Doctor of Medicine.—The examination for this degree takes place twice in each year, commencing on the first Monday in December and on the first Monday in July. Candidates must have taken the degrees of M.B., B.S. not less than two years previously, but for those who have taken the M.B., B.S. degrees with honours, or have done certain original work, this period of delay may be reduced to one year. Candidates who have obtained their M.B. degrees in or before May, 1904, will not be required to hold the degree of B.S. before seeking the doctorate. They may present themselves for examination in one of the following branches, namely: (1) Medicine; (2) Pathology; (3) Mental Diseases; (4) Midwifery and Diseases of Women; (5) State Medicine; and (6) Tropical Medicine. Any candidate for the degree of M.D. may transmit to the Registrar, not less than two months before the commencement of the examination, a thesis or published work embodying the result of his own independent research in the branch of Medicine in which he is a candidate, and if the thesis be approved by the examiners, the candidate may be exempted from the written examination in that subject. The fee is £20, and for re-examination £10.

Master in Surgery.—The examination takes place twice in each year, and commences on the first Mondays in December and July. Candidates must produce certificates of having taken the degrees of M.B. and B.S. not less than two years previously (with certain exceptions, as in the examination for the M.D.) and of having subsequently held for at least six months a resident or non-resident Surgical hospital appointment. The fee is £20, and for re-examination £10.

Full details can be obtained free on application to the Academic Registrar, University of London, South Kensington, S.W. Students should apply direct to the University for this detailed information.

UNIVERSITY OF LONDON, UNIVERSITY COLLEGE.—FACULTY OF MEDICAL SCIENCES.—The Faculty of Medical Sciences comprises Physics, Chemistry, Botany and Zoology, also the Departments of Anatomy, Physiology, and Pharmacology (the Intermediate Medical Sciences), and the Departments of Hygiene and Public Health, and of Pathological Chemistry (Post-graduate Study). Full Preliminary and Intermediate Courses of study are provided for students desirous of obtaining the medical degrees of the University of London and as well as for students seeking the qualifications of other Universities and licensing bodies. University and King's Colleges have been constituted University Centres for the teaching of the Medical Sciences. A student can enter the College directly, and at the end of the first and second courses select the Medical School and Hospital.

Scholarships and Exhibitions.—Five annual University Entrance Exhibitions of £40 a year, six similar scholarships of £50 a year each in science subjects are annually awarded, and three Andrews' Entrance Scholarships. The Bucknill Scholarship of 135 guineas and two Exhibitions of 55 guineas are awarded on the results of an examination held in July. The Cluff Memorial Prize, value £15, is awarded for proficiency in Anatomy, Physiology, and Chemistry; the Schäfer Prize in Physiology, value £18, for proficiency in Physiology; the Sharpey Physiological Scholarship, value £150, for Research in Physiology.

Composition Fees.—Course for the first Medical Examination, 26 guineas; course for the second Medical Examination, 58 guineas; course for the first Examination of the Conjoint Board, 21 guineas; course for the second Examination of the Conjoint Board, 58 guineas.

The London Medical Schools recognised by the University with the title of "University of London," are:—University College, King's College, St. Bartholomew's Hospital Medical School, St. Thomas's Hospital Medical School, Westminster Hospital Medical School, Guy's Hospital Medical School, London Hospital Medical College, Middlesex Hospital Medical School, Charing Cross Hospital Medical School, St. Mary's Hospital Medical School, Royal Army Medical College, London School of Tropical Medicine, School of Medicine for Women, and the Lister Institute of Preventive Medicine.

UNIVERSITY OF LONDON—KING'S COLLEGE, LONDON, STRAND.—In the medical division of the Faculty of Science students are prepared for their first examination (Chemistry, Physics, Biology), and for their second examination (Anatomy, Physiology, and Pharmacology), by the University Professors attached to King's College, London, and their assistants. At present four medical schools, viz., those attached to King's College Hospital, Westminster Hospital, St. George's Hospital, and Charing Cross Hospital, the teaching in which is restricted to the subjects of the final examinations, send their students to King's College for the purpose of tuition in the above-mentioned preliminary and intermediate studies. Numerous Scholarships and Prizes are offered.

Department of Public Health and Bacteriology.—This department of King's College is carried on in large laboratories in the Charing Cross Hospital Medical School Building, Chandos Street.

Full particulars as to courses of study, laboratory accommodation, hours, fees, etc., can be obtained on application to the Dean, Professor Halliburton, or the Secretary, Mr. Walter Smith, at the College.

UNIVERSITY OF DURHAM.

Two diplomas, one Licence and six degrees in Medicine and Hygiene are conferred—*viz.*, the degrees of Bachelor of Medicine, Bachelor of Surgery, Master of Surgery, Doctor in Medicine, Bachelor of Hygiene, and Doctor of Hygiene, Diploma in Public Health and Diploma in Psychiatry and the Licence in Dental Surgery. These degrees, diplomas and licence are open to both men and women.

For the degree of Bachelor of Medicine (M.B.), there are four professional examinations. The subjects are: For the first: elementary anatomy, biology, chemistry, and physics. For the second: Anatomy and physiology. For the third: Materia medica and pharmacy, pathology and elementary bacteriology, medical jurisprudence and public health; and for the fourth: Medicine, clinical medicine and psychological medicine, therapeutics, surgery and clinical surgery, midwifery, and diseases of women and children, and clinical gynæcology.

It is required that one of the five years of professional education shall be spent in attendance at the University College of Medicine and the Royal Victoria Infirmary, Newcastle-upon-Tyne. First and second year students (dating from registration) are not required to comply with the regulation regarding attendance on hospital practice. Candidates who have passed the First and Second Examinations of the University will be exempt from the First and Second Examinations of the Conjoint Board.

For the degree of Bachelor of Surgery (B.S.) every candidate must have passed the examination for the degree of Bachelor of Medicine of the University of Durham, and must have attended one course of lectures on operative surgery, and one course on regional anatomy. Candidates will be required to perform operations on the dead body, and to give proof of practical knowledge of the use of surgical instruments and appliances.

For the degree of Master of Surgery (M.S.) candidates must not be less than twenty-four years of age, and must satisfy the University as to their knowledge of Greek or German. In case they shall not have passed in either of these subjects at the Matriculation Examination for the M.B. degree, they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they can proceed to the higher degree of M.S. They must also have obtained the degree of Bachelor of Surgery of the University of Durham, and must have been engaged for at least two years subsequently to the date of acquirement of the degree of Bachelor of Surgery in attendance on the practice of a recognised hospital, or in the naval or military services, or in medical or surgical practice.

For the degree of Doctor of Medicine (M.D.) candidates must be not less than twenty-four years of age, and must satisfy the University as to their knowledge of Greek or German. In case they shall not have passed in either of these subjects at the Matriculation Examination for the M.B. degree, they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they proceed to the higher degree of M.D. They must also have obtained the degree of Bachelor of Medicine of the University of Durham, and must have been engaged for at least two years, subsequently to the date of acquirement of the degree of Bachelor of Medicine, in attendance on the practice of a recognised hospital or in the naval or military services, or in medical or surgical practice.

Candidates for any of the above degrees must give at least twenty-eight days' notice to the Secretary of the College of Medicine, Newcastle-on-Tyne. In the case of the M.D. (Essay) Examination, candidates must send in their essays six weeks before the date of the examination.

The New Royal Victoria Infirmary, containing 400 beds, was opened by the late King, in July, 1906. In the new infirmary adequate accommodation is provided for the study of the various special subjects, in addition to the ordinary clinical work. Practical midwifery can be studied at the Newcastle Maternity Hospital. Opportunities for practical study are also afforded by the Dispensary, City Infectious Diseases Hospital, Eye Infirmary, and at the Northumberland County Lunatic Asylum.

There are various appointments open to students, whilst the scholarships available are numerous and of considerable value.

Fees.—(*a*) A composition ticket for lectures at the college may be obtained—1. By payment of 72 guineas on entrance. 2. By payment of 46 guineas at the commencement of the first sessional year and 36 guineas at the commencement of the second sessional year. 3. By three annual instalments of 36, 31, and 20 guineas, respectively, at the commencement of the sessional year. A Composition Ticket for the course of lectures and practical work of the first two years of the curriculum may be obtained by the payment of 40 guineas on entrance. (*b*) Single courses of lectures, five guineas. (*c*) Fees for attendance on hospital practice: For three months' medical and hospital practice, six guineas; for six months, ten guineas; one year, fifteen guineas; composition fee in one payment, thirty-five guineas; or by two instalments—*viz.*, first year, twenty guineas; second year, eighteen guineas. In addition, two guineas yearly up to three years must be paid to the Committee of the Royal Infirmary. (*d*) Composition fee for lectures, &c., at the College for the Licence in Dental Surgery, 34 guineas. Composition fee for dental practical work at Newcastle Dental Hospital, 35 guineas.

A Licence in Dental Surgery has been instituted. Before admission to the Final Examination, each candidate must furnish evidence, (1) of having attained the age of 21 years, (2) of having undergone a three-years' pupilage in mechanical dentistry with a registered dentist, and (3) of having been engaged in professional study for at least four years subsequent to registration as a dental student. He must also sign such declaration as the University may determine, binding himself not to advertise for professional purposes. Examinations are held concurrently with the medical examinations, and the fees payable by candidates amount to £15.

The Senate of the University has decided to grant a Diploma in Psychiatry, full particulars of which may be obtained from the College Calendar.

Further particulars will be given on application to Prof. Howden, Secretary, University of Durham College of Medicine, Newcastle-on-Tyne.

UNIVERSITY OF MANCHESTER.

Candidates for degrees in medicine and surgery (M.B., Ch.B., M.D., Ch.M.) must attend classes in the University during at least two years, and for three years must pursue a course of medical study at any college or medical school recognised by the University.

They are required to have passed the Matriculation Examination, or such other examination as may from time to time be recognised for this purpose by the University. The Matriculation Examination is held in July and in September.

Before admission to the Degrees of Bachelor of Medicine and Surgery candidates are required to send in the usual certificates of age and study as at the other Universities. All candidates for these Degrees must have attended approved courses of both lectures and laboratory work, and must pass four examinations.

The final examination cannot be taken before the fifth year of medical study. The subjects of examination are as follows: 1, Medicine, systematic and clinical, including mental diseases and diseases of children; 2, Surgery, systematic, clinical, and practical; 3, Obstetrics and diseases of women; 4, Forensic medicine and toxicology.

The regulations relating to the M.D. and Ch.M. Degrees can be obtained on application to the Registrar.

The first M.B and Ch.B. is held in March, June, September, and December. The second examination is held in December, and in March; the third examination in March, June and December; the Final in June and December; the examination for Ch.M. in June only.

Fees.—Matriculation examination, £2, subsequent examination in the same year, 30s. First examination, £5; for any subsequent examination, £2. The fees for the Second Examination and for the Third and Final Examinations are the same as for the First Examination. A fee of £10 is payable on the conferring of the degree of M.D., a fee of £5 on the conferring of the degree of Ch.M.

The buildings include large laboratories, dissecting-rooms, library and reading-rooms, and are on the most modern principles. Students wishing to engage in anatomical, physiological, or pathological research will find excellent opportunity for study in the complete and well-furnished laboratories. Hospital practice is taken out at the Royal Infirmary, which contains 592 beds. The Cheadle Lunatic Asylum, St. Mary's Hospitals, the Southern Hospital, and other special hospitals also afford teaching facilities of great importance.

The numerous appointments are of considerable monetary value. The principal are:—The Leech fellowship of £100; Honorary Research Fellowships; Junior Research Fellowships in Public Health, two of the value of £50, each annually; Entrance scholarships in medicine, £100 (towards University and Infirmary fees); Ashby Memorial Research Scholarship in Diseases of Children, £100, awarded triennially; Dreschfeld Memorial Scholarship £30, awarded annually; Turner Medical scholarship of £20 to students who have completed a course of medical study in the University; Robert Platt physiological scholarship of the value of £50; Robert Platt zoological and botanical scholarship, £50; Professor Tom Jones memorial surgical scholarship of £100, awarded triennially; two Dauntesey medical scholarships, one of £45 and one of £35; John Henry Agnew scholarship in diseases of children, value £30, awarded annually; Graduate scholarship in medicine, £25, awarded annually; and many prizes. Robert Platt Exhibitions in Physiology, £15, awarded annually; Robert Platt Biological Exhibitions, £15, awarded annually; Sidney Renshaw Exhibitions in Physiology, £15, awarded annually; Professor Tom Jones Exhibition in Anatomy, £25, awarded annually.

Fees.—For courses of instruction for the degrees of M.B., and Ch.B., of the University:—For the first M.B. examination the total cost amounts to about 30 guineas payable on entry. A composition fee of 70 guineas, payable in three instalments of 30, 20, and 20 guineas, at the commencement of the second, third, and fourth years of studentship respectively, admits to the courses of instruction required for the degrees of M.B. and Ch.B.

Dental Fees.—The composition fee for candidates for the University degree of Bachelor of Dental Surgery is 60 guineas, and for candidates for the University diploma in Dentistry is 55 guineas, payable in two equal instalments at the beginning of the first and third years of studentship.

UNIVERSITY OF BIRMINGHAM.

The University of Birmingham grants Degrees of M.B., Ch.B., M.D., Ch.M., and also a B.Sc. in the subject of Public Health. As a rule, in order to obtain any of these Degrees it is necessary that a student shall have passed at least the first four years of his curriculum in attendance upon the classes of the University, but the Senate has power of recognising attendance at another University as part of the attendance qualifying for these degrees.

Degrees of Bachelor of Medicine and Bachelor of Surgery.—The student must have passed either the Matriculation Examination of the University or one of the following examinations, which will be accepted in lieu thereof for the present:—(*a*) The previous examination of the University of Cambridge; (*b*) Responsions of the University of Oxford; (*c*) The matriculation examination of any recognised University; (*d*) The leaving certificate (higher) of the Oxford and Cambridge Boards; (*e*) The Oxford or Cambridge senior local examination.

Matriculation Examinations are held in July and September each year.

Degrees of Doctor of Medicine and Master of Surgery.—At the end of one year from the date of having passed the Final M.B., Ch.B. Examination, the candidate will be eligible to present himself for the higher Degrees of either Doctor of Medicine or Master of Surgery or both, the regulations for which may be had upon application to the Dean. The University also grants a Degree and a Diploma in Public Health, and provides adequate instructions for the same.

The Composition Fee for University Courses for Degrees of M.B., Ch.B. is £85; the Composition Fee for Clinical Instruction at the General and Queen's Hospitals is £42; *total* cost for the full M.B., Ch.B. Curriculum including Examination Fees is £158 2s. 6d.

Dental Department.—The University grants the Degrees of Bachelor and Master of Dental Surgery (B.D.S. and M.D.S.), and a Diploma in Dental Surgery (L.D.S.). The whole of the instruction for which may be taken out in the University, with which is associated the Birmingham Dental Hospital. The Clinical instruction of Dental Students is carried out under the direction of the University Dental Clinical Board.

The fees for L.D.S. Diploma courses are as follows:—Composition Fee (University Courses), £60; Clinical Fees for Dental and General Hospital Instruction, £31 10s.; total cost for L.D.S. including Examination Fees, £114 15s.*

The total cost for Degree of B.D.S. and Diploma of L.D.S. is £149 1s.

THE GENERAL AND QUEEN'S HOSPITALS.—The practices of these hospitals are amalgamated for the purpose of clinical instruction under the direction of the University Clinical Board, by whom all schedules will be signed and all examinations conducted. The hospitals have a total of upwards of 500 beds. 8,000 in-patients and 80,000 out-patients are treated annually, and many valuable posts are open to students at both.

---

* Does *not* include fee for Mechanical Pupilage, which is 85 gns

Further information can be obtained from Professor Peter Thompson, Dean of the Medical Faculty.

UNIVERSITY OF LIVERPOOL.

The Degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), and Master of Hygiene (M.H.). The course of study for the Degrees of Bachelor of Medicine and Bachelor of Surgery is of five years' duration, and of this period two years must be spent at the University, the remaining three years can be taken in any medical school approved by the University.

For the Degree of M.D., a thesis is required which may be presented not earlier than one year after graduation, as M.B., Ch.B.

The degree of Ch.M. is given after a period of at least one year of further study after graduation as M.B., Ch.B., on the results of an examination.

The degree of M.H. is given after two years' study and examinations, and includes the D.P.H.

Diplomas.—Diplomas have been instituted in Public Health (D.P.H.), Ophthalmic Surgery (D.Ch.O), Tropical Medicine (D.T.M.), and Veterinary Hygiene (D.V.H.). Special diplomas are also granted in Anatomy, Bacteriology, Bio-chemistry, and Parasitology after a course of study of three terms in the subject chosen and allied subjects.

Students may enter for the degrees of the University of Liverpool, or may study for the degrees, diplomas and qualifications of the other licensing bodies.

Hospitals.—The Clinical School of the University consists of four general hospitals—the Royal Infirmary, the David Lewis Northern Hospital, the Royal Southern Hospital, and the Stanley Hospital; and of five special hospitals—the Eye and Ear Infirmary, the Hospital for Women, the Infirmary for Children, St. Paul's Eye Hospital, and St. George's Hospital for Skin Diseases. These hospitals contain in all a total of 1,076 beds. The organisation of these hospitals to form one teaching institution provides the medical student and the medical practitioner with an unrivalled field for clinical education and study, and all are within easy access from the University. The period of hospital practice extends over the last three years of medical study. There are a large number of appointments to House Physicianships and Surgeonships both at the general and special hospitals, which are open to qualified students of the School. These appointments (20) in most cases carry salaries varying from £60 to £100 per annum.

Fellowships and Scholarships.—Fellowships, Scholarships, and Prizes of over £1,000 are awarded annually. Eight Fellowships, each of the value of £100, are awarded annually for research in Anatomy, Physiology, Pathology, Bacteriology, Gynæcology, and Bio-Chemistry, and in one or two cases are renewable. Two Lyon Jones scholarships, of the value of £21 each for two years, are awarded annually—a Junior Scholarship, open at the end of the first year of study to Liverpool University students in the subjects of the first M.B. Examinations, and a Senior Scholarship, open to all students in the school at the end of the second or third year of study, in the subjects of Anatomy, Physiology, Materia Medica, and Pharmacology. A University Scholarship of £25 awarded on the results of the second examination for the degree. The Derby Exhibition of £15 for one year is awarded in Clinical Medicine and Surgery in alternate years. Students may compete in their fourth and fifth years. A Clinical School Exhibition of £15 awarded under similar conditions. The Torr Gold Medal in Anatomy, the George Holt Medal in Physiology, the Kanthack Medal in Pathology, and the Robert Gee Book Prize, of the value of £5, for Children's Diseases.

Entrance Scholarships.—Two Robert Gee Entrance Scholarships, of the annual value each of £25 for two years, are offered annually for competition. The holder is required to take out the First M.B. Course for the University Degree in Medicine.

The University also grants a Diploma in Dental Surgery (L.D.S.) and Degrees in Dental Surgery (B.D.S. and M.D.S.). The courses of systematic instruction are given in the University buildings, five minutes walk from the Dental Hospital.

Communications should be addressed to the Dean, Mr. K. W. Monsarrat, F.R.C.S., the University, Liverpool.

LIVERPOOL SCHOOL OF TROPICAL MEDICINE.

The Diploma of Tropical Medicine, University of Liverpool.—The school is affiliated with the University of Liverpool and the Royal Southern Hospital of Liverpool. The instruction given occupies six hours a day for five days a week during thirteen weeks. Each Course consists (1) of a systematic series of lectures on tropical medicine and sanitation delivered by the Professor of Tropical Medicine at the University; (2) of additional lectures on special African and other diseases delivered at the University; (3) of systematic lectures and demonstrations on tropical pathology, parasitology and bacteriology by the Walter Myers Professor, at the University; (4) of similar instruction on medical entomology by the Professor of Entomology at the University; (5) of clinical lectures and demonstrations delivered at the Royal Southern Hospital by the Physician in charge of the Tropical Ward, the Professor, and the Walter Myers Lecturer; and of lectures or demonstrations by assistant teachers.

In December and April an examination is held by the University for its Diploma of Tropical Medicine (D.T.M.), which is open only to those who have been through the course of instruction of the school. The examination lasts three days, and consists (1) of papers on tropical medicine, tropical pathology, and tropical sanitation and entomology respectively; (2) of a clinical examination; and (3) of an oral examination.

The fee for the full course of instruction is thirteen guineas, with an extra charge of ten shillings and sixpence for the use of a microscope, if required. The fee for the examination is five guineas. Applications should be made to the Dean of the Medical Faculty, University of Liverpool, from whom prospectuses may be obtained.

Two University Fellowships of £100 a year each are open to students of the school, amongst others. Accommodation for Research work is to be had, both at the University laboratory of the school, and at its Research Laboratories at Runcorn (sixteen miles distant from Liverpool).

Since it was instituted ten years ago the school has employed thirty different investigators paid out of its funds, and has despatched to the tropics thirty scientific expeditions, many of the workers having been taken from among its students. The work done by them has been published in twenty-one special memoirs with many plates and figures, besides text books and numerous articles in the scientific press. From the beginning of 1907, however, the Memoirs have been succeeded by the Annals of Tropical Medicine and Parasitology, published by the Committee, and open to outside contributors. (Apply to the Secretary, B10, Exchange Buildings, Liverpool). The Mary Kingsley Medal is awarded by the School for distinguished work in connection with tropical medicine, and has been given to Colonel Bruce, Professor Koch, Dr. Laveran, Sir Patrick Manson, Lord Lister, Professor Looss, Professor Danielewsky, Dr. Charles Finlay, Mr. W. M. Haffkine, Professor Golgi, Colonel Gorgas, Professor Theobald Smith, and Rt. Hon. Joseph Chamberlain, M.P., and others.

UNIVERSITY OF BRISTOL.

The University grants the conjoined degrees in the Faculty of Medicine of M.B., Ch.B., the degree of M.D., Ch.M., B.D.S., and M.D.S.; also diplomas in Public Health (D.P.H.) and in Dental Surgery (L.D.S.).

The conjoined Degrees of M.B., Ch.B.—The curriculum occupies five years and a half. The University lectures and laboratory courses are attended in the large and well equipped new wing of the University. Hospital practice and Clinical instruction are provided in the allied hospitals, which together afford upwards of six hundred beds and a very large external midwifery department. Three years at least must be spent in the University, and two of them subsequently to passing the second examination.

Degree of B.D.S.—The curriculum occupies five years. Mechanical Dentistry may be studied in the new and well equipped University Laboratory under the supervision of a skilled mechanic. In this laboratory the whole of the mechanical work for both the Bristol Royal Infirmary and the Bristol General Hospital is done by the pupils. Lectures and ordinary laboratory work are attended in the University, the Metallurgical laboratory is in the Chemical department, and has been specially fitted for the purpose.

Diploma in Dental Surgery, L.D.S.—The curriculum occupies four years, and runs on very similar lines to that for the B.D.S. It is not, however, necessary to pass the matriculation examination, and some subjects required for the degree are omitted. Candidates for either the B.D.S. or L.D.S. must be registered Dental students.

Diploma in Public Health.—The necessary laboratory work is done in the University in the Chemical and Pathological departments. The remainder of the curriculum is taken under the Medical Officer of Health for the City and County of Bristol (Lecturer in Public Health) and the Assistant Medical Officer for the Port of Bristol (Demonstrator in Public Health).

N.B.—*Although the various courses are primarily designed for the University degrees and diplomas, equal attention is paid and equal facilities are offered to students who enter for the degrees of other Universities, such as the University of London, and for the diplomas of the various examining bodies.*

Women are admitted to all degrees and diplomas, and to the courses of study necessary for them. The University Hall of Residence is situated at Clifton, within a short distance of the University. Particulars of residence may be obtained from Miss M. C. Staveley, M.A., at the University.

Inclusive Fees.—For the M.B., Ch.B. curriculum, 140 guineas; for the B.D.S. curriculum (including mechanical pupilage), 190 guineas; for the B.D.S. curriculum (excluding mechanical pupilage), 115 guineas; for the L.D.S. curriculum (including mechanical pupilage), 168 guineas; for the L.D.S. curriculum (excluding mechanical pupilage), 93 guineas; for the D.P.H., 30 guineas. Arrangements can be made for paying these fees by instalments.

Appointments (Undergraduate).—Clinical Clerkships, Dresserships, also Ophthalmic, Obstetric, and Pathological Clerkships are tenable at the Bristol Royal Infirmary and the Bristol General Hospital. In these institutions the Dressers reside in rotation free of charge.

Appointments (Post-Graduate).—At the Bristol Royal Infirmary:—Two House Surgeons, £100 each per annum; two House Physicians, £100; Resident Obstetric and Ophthalmic House Surgeon, £75; Throat, Nose, and Ear House Surgeon, £75; Casualty Officer, £50: Dental House Surgeon, £100. All these appointments are made for twelve months, except that of Casualty Officer, which is for six months. From the resident officers a Senior Resident Officer is appointed at an additional salary of £30. At the Bristol General Hospital:—Senior House Surgeon, £150 per annum; Casualty House Surgeon, £105 per annum if another resident appointment has been previously held; two House Physicians, £80; House Surgeon, £80; Dental House Surgeon, £200 per annum. All these appointments are for six months, except that of Dental House Surgeon, which is for two years.

The Winter Session opens on September 30th.

UNIVERSITY OF LEEDS.

The school of medicine attached to this University was founded in 1831 as the Leeds Medical School. The building, erected on a site contiguous to the infirmary, contains one of the finest dissecting-rooms in the United Kingdom, extensive laboratories for physiology and pathology with the most recent improvements in fittings and apparatus, ample lecture-room accommodation, a large library, and separate museums for pathology and anatomy. Professors and lecturers are attached, and the clinical teaching is given by the physicians and surgeons attached to the Leeds General Infirmary, one of the largest in the United Kingdom, having 520 beds, with a staff of physicians and surgeons of considerable eminence. Ophthalmic demonstrations and demonstrations of skin diseases are given in the infirmary by surgeons in each department, where also are obtainable various clinical clerkships, dresserships, and other appointments; and an extern maternity charity is attached, at which the necessary attendance at labours can be taken. Besides the infirmary there is a large dispensary, a large hospital for infectious diseases, a hospital for women and children, and a maternity hospital, all of which are open to students of the school.

Scholarships, Prizes, etc.—(1) An entrance scholarship of £73 2s. 6d. There is also a Hardwick prize in clinical medicine, a McGill prize in clinical surgery, each of the value of £10. Thorp scholarship of about £25 a year in forensic medicine and hygiene, and a Scattergood prize of £5 in midwifery, besides silver and gold medals and other class prizes. The composition fee for attendance upon all the required courses of school lectures is £73 2s. 6d. for University students who have attended the preliminary scientific courses, and the same for non-University students, exclusive of chemistry and biology.

The composition fee for medical and surgical practice and clinical lectures is £42 in one sum, or two instalments of £22 each. These fees are not included in the composition fees for lectures and are payable separately.

A scholarship of £42 to cover the cost of medical and surgical practice is offered annually by the University.

Degrees and Diploma in Dental Surgery are obtainable at this University, being Bachelor of Dental Surgery (B.Ch.B.), and Master of Dental Surgery (M.Ch.D.). Candidates for the degree of Bachelor of Dental Surgery are required to have passed the Matriculation Examination, to have pursued thereafter approved courses of study for not less than five academic years, two of such years at least having been passed in the University subsequently to the date of passing Parts I. and II. of the first examination, and to have completed such period of pupilage or hospital attendance, or both, as may be prescribed by the Regulations of the University. No candidate shall be admitted to the degree who has not attained the age of twenty-one years on the day of graduation.

Candidates for the diploma in Dental Surgery are required to present certificates showing that they have attained the age of twenty-one years, that they have attended courses of instruction, approved by the University, extending over not less than four years, two of which must be spent in the University, and that they have completed a pupilage of three years, two of such years at least having been taken before the First Professional examination. Candidates are required to satisfy the Examiners in the several subjects of the following examinations: A preliminary examination in Arts; a Preliminary examination in Science; the First Professional examination; and the Final examination.

A Diploma in Public Health (D.P.H.) is granted after examination under the usual regulations, also a Diploma in Psychological Medicine.

UNIVERSITY OF SHEFFIELD.

By the Charter granted in 1905, this University is permitted to grant degrees in medicine. All its courses and all its degrees are open, without restriction, to both sexes. The new buildings of the University, opened by his late Majesty King Edward in 1905, are situated at the west end of the city, overlooking on two sides the adjoining Weston Park. The medical department occupies the entire north wing of the University quadrangle, and is within easy reach of the various hospitals, with which it is connected for clinical purposes.

These are as follows:—The Royal Infirmary contains 326 beds, and the Royal Hospital 191 beds. The practices of the two Institutions are amalgamated for the purpose of clinical instruction, giving a total of over 500 beds for the treatment of medical, surgical and special cases. During the last year over 6,000 patients passed through the wards of the two institutions, while those attending as out-patients numbered over 45,000. The Jessop Hospital for Diseases of Women contains 80 beds, with about 900 in-patients, and over 3,000 out-patients; also a Maternity Department, with about 450 in-patients per annum, and about 700 out-patient cases attended. Special courses on fevers are held at the City Fever Hospitals (570 beds), and on Mental Diseases at the South Yorkshire Asylum (1,610 beds).

Appointments.—The following are open to all students who have passed their examinations in anatomy and physiology:—Casualty Dresserships, Surgical Dresserships, Medical Clerkships, Pathological Clerkships, Ophthalmic Clerkships, Clerk to the Skin Department, etc.

Fees.—Composition fee of £80, payable in three instalments, viz.:—£24 at commencement of first year of study; £28 at commencement of second year of study; £28 at commencement of third year of study. This composition fee entitles the student to attendance on all the courses of lectures and practical classes, required for a degree course in the University, or for the ordinary qualifications in medicine and surgery of the examining boards.

Composition Fee for Medical, Surgical, Gynæcological and Obstetrical Hospital Practice (except Pharmacy).—Fee for the full period of hospital practice required by the examining boards:—£49 17s. 6d., payable in three instalments.

Dental Department.—In connection with the University there is a complete dental department, which is fully recognised by the various examining bodies, and students are able to get their full curriculum here.

Scholarships and Fellowships.—Entrance Medical Scholarship of the value of from £122 to £130, open to both sexes, awarded in June each year. Four Town Trustees' Scholarships, value £50, tenable for three years. Town Trustees' Fellowship, value £75, open to graduates of the University, tenable for one year. Mechanics' Institute Scholarship, value £50, tenable for one year, and renewable for a second year. The Frederick Clifford Scholarship, value about £50 per annum, tenable for two years, open to graduates of the University; and the Kaye Scholarship, value about £22 10s. A Gold Medal is offered annually for the best student in clinical medicine and clinical surgery. A Bronze Medal is awarded annually to the student who has gained first place in the examination for the full course in each year.

Degrees.—Candidates for a medical degree must have matriculated in the University or have passed such other examination as may be recognised for this purpose by the University and sanctioned by the Joint Matriculation Board. The subjects required by the General Medical Council must be included in the matriculation examination, or its recognised substitute. The degrees in medicine obtainable are Bachelor of Medicine and Bachelor of Surgery (M.B., Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.); conditions and particulars of which may be obtained on application to the Dean.

At the University of Sheffield post-graduate courses are held annually. These courses are specially arranged for practitioners, and the work done is mainly clinical and practical.

A Diploma in Public Health is also granted by the University.

UNIVERSITY OF WALES.

The School of Medicine, in University College, Cardiff, which is one of the constituent colleges of the University of Wales, has since its foundation, in 1883, prepared students for the Preliminary Scientific Examination of the University of London, and for the corresponding examinations of other licensing bodies. Chairs of Anatomy, Physiology and Pathology and Bacteriology and Lectureships in Materia Medica and Pharmacy and Histology and Embryology have been established, making it possible for students of medicine to spend three out of the five years of prescribed study at Cardiff. Arrangements with the managing committee of King Edward VII.'s Hospital, Cardiff, give students of the College the privilege of attending this large and well-ordered hospital, which is situated within five minutes' walk of University College. Many students, especially from Wales and Monmouthshire, avail themselves of the opportunities thus afforded to pursue the earlier part of the medical curriculum near home. All classes are open alike to both men and women students over sixteen years of age. The courses of instruction given at Cardiff are recognised as qualifying for the examinations of the Universities, Royal colleges, and other licensing bodies of Great Britain and Ireland. Having spent at least three years in study at Cardiff, and having passed the examinations in these years, a student may proceed to London or elsewhere and complete his qualifying course for a University degree or for a college diploma.

Students preparing for the first and second examinations of the Conjoint Board for England, or for the corresponding examinations of the Conjoint Board for Scotland, may compound for their classes by paying a single composition fee of £41 10s., or by paying £20 and £24 10s. at the beginning of their first and second years respectively. Those preparing for the First and the Second Examinations for Medical Degrees of the University of London may compound for their three years' instruction at Cardiff by paying a single composition fee of £63, or by paying £20, £28 and £21 at the beginning of their first, second and third years respectively.

In 1899 a department of Public Health was established, and lecturers in bacteriology and in public health and hygiene were appointed. Medical men preparing for the diploma in Public Health and Hygiene of the University of Wales can attend complete courses of lectures and laboratory instruction in this department. These courses are also recognised by the University of Cambridge, by the Royal Colleges of Physicians and Surgeons, by Victoria University, and other Examining Boards.

In the case of medical students, attendance on the class of hygiene and public health is accepted by the Universities of London and Cambridge, and by the Conjoint Examining Board of England

Courses of lectures to midwives, adapted to the requirements of the Central Midwives Board, under the Midwives Act, are commenced in October, January, and April. The lectures are suitable both for pupil midwives and practising midwives, as well as for nurses who desire to enter for the examination for certification under the Act.

Scholarships and Free Studentships.—The attention of students about to matriculate is drawn to the entrance scholarships and Free Studentships which are offered at the college for competition in April, most of which may be held by medical students. Full particulars of the examination for these may be obtained from the Registrar, or from the Dean of the Medical Faculty.

THE ENGLISH COLLEGES.

The medical corporations in England are the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Society of Apothecaries of London. The two Royal Colleges now co-operate to hold a series of examinations, on passing which the candidate receives the diploma of Licentiate of the Royal College of Physicians (L.R.C.P.), and Member of the Royal College of Surgeons (M.R.C.S.). The Society of Apothecaries grants a complete diploma (L.S.A.) in medicine, surgery, and midwifery.

Conjoint Examining Board in England.

Candidates for the above licences are required to complete five years of professional study at recognised medical schools and hospitals, after passing the preliminary examination, of which six months may be spent at an institution recognised by the Board, to comply with the following regulations and to pass the examinations hereinafter set forth.

Professional Examinations.—There are three examinations, each being partly written, partly oral, and partly practical. These examinations are held in the months of January, April, July, and October, unless otherwise appointed, fourteen clear days' notice before the day on which the examination commences being required, the candidate transmitting at the same time the required certificates. The subjects of the first professional examination are Part I., Chemistry; Part II., Physics; Part III., Elementary Biology; and Part IV., Practical Pharmacy. Candidates may present themselves immediately after passing the preliminary examination in general education, provided they are able to produce the certificates required. They must present themselves for examination in Parts I. and II. together, until they have reached the required standard to pass in both or in one of these parts, but they will not be allowed to pass in one part unless they obtain at the same time at least half the number of marks required to pass in the other part. Candidates may take Parts III. and IV. separately, or they may present themselves for the whole examination at one time. Practical Pharmacy may be taken with, or at any time before Part I. of the Final Examination. Candidates who shall produce satisfactory evidence of having passed an examination for a degree in medicine in any of the subjects of this examination conducted at a University in the United Kingdom, India, or in a British Colony, will be exempt from examination in those subjects in which they have passed.

The fee for admission to the first examination is as follows:—For the whole examination, £10 10s.; for re-examination after rejection in Parts I. and II., £3 3s.; and for re-examination in each of the other parts, £2 2s.

The subjects of the second examination are anatomy and physiology. Candidates will be required to pass in both subjects at one and the same time. The study of anatomy and physiology will not be recognised until candidates have passed in two of the first three parts of the first examination. Candidates will be admissible to the second examination fifteen months from the date of passing the required subjects of the first examination.

Candidates referred at the second examination will be required, before being admitted to re-examination, to produce certificates that they have pursued, to the satisfaction of their teachers, in a recognised place of study, their anatomical and physiological studies during a period of not less than three months subsequently to the date of their reference.

The fees for admission to the second examinations are: £10 10s. for the whole examination, and £6 6s. for re-examination after rejection.

The subjects of the third and final examinations are:—Part I. Medicine, including medical anatomy, pathology, practical pharmacy, therapeutics, forensic medicine and public health. Candidates who have passed in practical pharmacy at the first examination will not be re-examined in that subject at the third examination. Part II. Surgery, including pathology, surgical anatomy, and the use of surgical appliances. Part III. Midwifery and gynæcology. Candidates may take this examination in three parts separately, or they may present themselves for the whole examination at one time, provided that Midwifery may not be taken until the whole curriculum is completed.

Fees for admission to the third or final examination are as follows:—For the whole examination, £21 0s. Part I.—For re-examination in medicine, including medical anatomy, pathology, therapeutics, forensic medicine and public health, £5 5s.; for re-examination in practical pharmacy (if taken at this examination), £2 2s. Part II.—For re-examination in surgery, including pathology, surgical anatomy, and the use of surgical appliances, £5 5s. Part III.—For re-examination in midwifery and gynæcology, £3 3s.

Candidates referred on the third or final examination, or on one or more of the three parts into which they may have divided it, will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and will be required, before being admitted to re-examination, to produce a certificate, in regard to medicine and surgery, of having attended the medical and surgical practice, or the medical or surgical practice, as the case may be, during the period of his reference; and in regard to midwifery and diseases peculiar to women a certificate of having received, subsequently to the date of his reference, not less than three months' instruction in that subject by a recognised teacher. A candidate who possesses a registrable qualification is admissible to re-examination without producing additional certificates.

Regulations for Colonial, Indian, and Foreign Candidates, and University Candidates.

Persons holding a Colonial, Indian, or a foreign qualification entitling them to practise medicine in the country of origin, and conferred after a course of study and examinations equivalent to those required by the Royal Colleges, are admissible to the second and third (final) examinations forthwith.

Members of a University in the United Kingdom and Graduates of Medicine of certain recognised Colonial or Foreign Universities are, under certain conditions, eligible for admission to the third (final) examination two years after passing at the University in the subjects included in the first and second examinations of the Board.

Royal College of Physicians of London.

Members.—The membership of the College is granted after examination to persons above the age of 25 years who do not engage in trade, do not dispense medicine, and do not practise in partnership. This diploma is only granted to persons already registered, or who have passed the final examination for the licence.

Medical graduates of a recognised University are admitted to a pass examination, but others must have passed the examinations required for the licence of the College. The examination, which is held in January, April, July, and October, is partly written and partly oral. It is directed to medicine, and is conducted by the president and censors. Candidates under 40, unless they have obtained a degree in arts in a British University, are examined in Latin, and either Greek, French, or German. Candidates over 40 are not so examined, and the examination in medicine may in their case be modified under conditions to be ascertained by application to the Registrar. The fee for the membership is £42, but if the candidate is a licentiate £15 15s. is deducted. In either case £6 6s. has to be paid before examination.

Royal College of Surgeons of England.

Membership.—The candidates are now subject to the regulations of the Conjoint Board.

Fellowship.—The Fellowship of the College of Surgeons is granted after examination to persons at least 25 years of age, who have been engaged in professional studies for six years. There are two examinations—the first in anatomy and physiology, which may be passed after the third winter session; the second chiefly directed to surgery, which may be passed after six years of professional study. The second examination may be passed before attaining the age of 25, but the diploma is not granted until that age is reached. Candidates for this part of the examination must have passed the final examination of the Conjoint Board in England, and have been admitted members of the College before they can be admitted thereto, except in the case of graduates in medicine and surgery of recognised Universities of not less than four years' standing. The diploma of Fellow is granted to successful women candidates subject to the provisions of the Medical Act, 1876, and of the Bye-Laws of the College.

Fees.—First examination, £5 5s.; second examination, £12 12s. The total fee payable on admission to the Fellowship is £31 10s., except for members, when the fee is £21. (The examination fees to the extent of £17 17s. count as part of the total fee.) Further information can be obtained on application to the Secretary of the Examining Board in England, Examination Hall, Queen Square, Bloomsbury, London, W.C.

Society of Apothecaries of London.

Primary Examination.—This examination consists of two parts: Part I.—Elementary biology, Chemistry, Chemical physics, including the elementary mechanics of solids and fluids; Heat, Light, and Electricity. Practical chemistry, Materia medica, and Pharmacy. A synopsis indicating the range of the subjects may be obtained on application. Part II.—Anatomy and Physiology and Histology. The examination is held in January, April, July, and October.

The final examination is held monthly, except the month of September, and is divided into Sections 1 and 2.

Section 1 consists of three parts:

Part I. includes: Principles and Practice of Surgery, Surgical Pathology, and Surgical Anatomy, Operative Manipulations, Instruments and Appliances.

Part II. includes: (*a*) The Principles and Practice of Medicine, including Therapeutics, Pharmacology, Pathology, and Morbid Histology. (*b*) Forensic Medicine, Hygiene, Theory and Practice of Vaccination; and Mental Diseases.

Candidates passing either (*a*) or (*b*) will not be re-examined therein.

Part III. includes: Midwifery, Gynæcology, and Diseases of New-born Children, Obstetric Instruments and Appliances. Candidates may enter for Parts I., II., and III. together or separately.

Section 1 of the Final Examination, or any part thereof, cannot be passed before the expiration of 45 months from the date of commencement of medical study.

Section 2.—This section consists of two parts:

Part I.—Clinical Surgery.

Part II.—Clinical Medicine and Medical Anatomy. Section 2 cannot be passed before the expiration of the fifth year.

Fees.—Primary examination, £5 5s.; final examination, £15 15s.; total fee, £21.

Further information, with particulars as to the course of study and of the certificates required, can be obtained from the Secretary to the Court of Examiners, Apothecaries' Hall, E.C.

This licence is a registrable diploma in Medicine, Surgery, and Midwifery, and qualifies the holder to compete for medical appointments in the Army, Navy, and Indian Services, also for Poor-law, Civil, and Colonial appointments.

The Gillson scholarship in Pathology of the annual value of £90, tenable for one year, is open to Licentiates of the Society and to candidates for the diploma who obtain it within six months of election to the scholarship. An examination in the art of prescribing is held annually, in January, at which the following prizes are awarded:—A gold medal of the value of £6; a silver medal, and a prize of books.

LONDON SCHOOLS.

The Schools of Medicine in the Metropolis are the following, the scholarships, prizes, students' appointments, fees, &c., being set forth in connection with each place named. The names of the hospital staff, lecturers, residential terms, and detailed information will be found, as a rule, in our advertisement columns.

St. Bartholomew's Hospital.—This hospital has 750 beds, and for many years past the school attached has had a larger number of students than any other medical school in London. Laboratories have been specially equipped for the study of pathology, bacteriology, public health, chemistry, biology, physics, and chemical pathology, and two additional operation theatres, new casualty and out-patients' departments, eight special departments, quarters for the junior staff, a dining-hall and a common-room for students have recently been built. Collegiate residence is permissible, subject to the ordinary rules.

Appointments.—Ten house physicians and ten house surgeons are appointed annually. During the first six months of office they act as "junior" house physicians and house surgeons, and receive a salary of £25 a year. During their second six months they become "senior" house physicians and house surgeons, and are provided with rooms by the hospital authorities, and receive a salary of £80 a year. A resident midwifery assistant, an ophthalmic house surgeon, and a house surgeon for diseases of the throat and nose are appointed every six months, and are provided with rooms and receive a salary of £80 a year. Two assistant anæsthetists are appointed, and receive salaries of £120 and £100 a year respectively. An extern midwifery assistant receives a salary of £80 a year. Chief assistants and clinical assistants are also appointed in each of the special departments.

Scholarships, &c.—There are three open scholarships in science, £75, £75, £150, tenable for one year, and an Entrance Scholarship in Arts, value £100, and the Jeaffreson exhibition, value £50; at the end of first year four junior scholarships of £30, £20, £25, £15, respectively; Treasurer's prize for practical anatomy; Foster prize in practical anatomy; senior scholarship, value £50, for anatomy, physiology, and chemistry; Wix prize, Hichens prize, two Brackenbury scholarships, of £39, in medicine and surgery; Bentley prize, for reports of cases; the Kirkes gold medal for clinical medicine, with scholarship of £30. Shuter scholarship of £50; Skynner prize of £15; Sir G. Burrows' prize of £10; Matthews Duncan prize, medal and about £20; Willett medal and Walsham prize; Holden Research Scholarship in Surgery, value £105; Lawrence Research scholarship and gold medal, value £115 for pathology.

Composition Fees.—(1) For students commencing their medical studies, one sum on entrance, 165 guineas; or by four instalments of 45 guineas. (2) For students who have passed an examination in preliminary science, in one sum on entrance, 145 guineas; or by instalments. (3) For students who have finished two years of medical study but have not passed an examination completing their anatomical and physiological studies; if paid in one sum on entrance, 110 guineas; or by annual instalments. (4) For students who have completed three years of medical study but have not passed an examination in anatomy and physiology, 90 guineas; or by annual instalments. (5) University students who have passed an examination completing their anatomical and physiological studies, in one sum, 80 guineas; or by instalments.

Fees for preliminary scientific students:—20 guineas; for laboratory instruction for D.P.H., 15 guineas. Fuller details will be supplied on application to the Dean.

Charing Cross Hospital.—The School attached to this Hospital is situated in Central London, and contains new pathological and bacteriological laboratories, pharmacological, materia medica, and public health, laboratories, theatre. Clinical instruction is given in medicine, surgery, and obstetrics, and in the special departments, diseases of the skin, diseases of children, mental disorders, the throat, the eye, nose and ear, and in the orthopædic, Röntgen and electrical departments.

The school arranges for a complete education in all departments, with special teachers for all preliminary and intermediate subjects.

By arrangement with the University of London, all students for the Primary and Intermediate portions of the curriculum carry out the necessary courses of instruction at King's College Laboratories, situated within a few minutes' walk from the Hospital. The entire teaching of the school is devoted to pathological, clinical and other subjects of final studies.

Appointments.—Salaried resident medical officer, medical and surgical and obstetric registrars (annual). Twelve resident house physicians, twelve house surgeons, and two obstetric officers are appointed each year, after competitive examinations.

Fees.—The fees for the five years' curriculum may be paid either by composition fee, in one sum, on joining, or by sessional payment system.

London University Students.—10 guineas entrance, and 25 guineas annually. Composition fee (5½ years) 120 guineas.

Conjoint Diploma Students.—10 guineas entrance, 22 guineas annually. Composition fee (5 years), 110 guineas. Payment may also be made for individual classes and hospital practice when taken separately.

Final Students.—Students of any university in the United Kingdom who have passed the examinations in anatomy, physiology, chemistry, and other preliminary subjects, may here complete their studies on payment of an annual fee of 25 guineas, or of 55 guineas (3 years' course) in one sum.

The fees for *Dental Students* for the two years' curriculum may be paid :—(*a*) in one sum of 45 guineas on entry (2 years' course) ; (*b*) in two instalments—one of 27 guineas on entry, and the second of 22 guineas at the commencement of the second twelve months.

Prospectus and further information can be obtained on application to the Dean (Dr. William Hunter, F.R.C.P.), Medical College, Charing Cross Hospital, W.C.

St. George's Hospital. — This hospital is situated in the West End, facing Hyde Park, and is readily accessible from all parts of London or the suburbs. It has recently undergone extensive alterations and improvements, has a service of 436 beds, of which 100 are at the Atkinson-Morley Convalescent Hospital at Wimbledon, and contains special wards for ophthalmic cases and diseases of women.

Appointments.—Eight house physicians and eight house surgeons, entitled to reside and board in the hospital free of expense ; twelve general assistants, six assistants in the special departments. Candidates for the above offices are selected quarterly by competition from among the perpetual pupils, sixteen pupils being in office at any one time. Obstetric assistant with a yearly salary at the rate of £50 and board and residence in the hospital ; curator of the museum with a salary of £200 ; assistant curator with a salary of £100 ; a medical registrar, with a salary of £200 per annum ; a surgical registrar with a salary of £200 per annum ; a resident anæsthetist with a salary of £100 per annum ; an administrator of anæsthetics with a salary of £50 and two with salaries of £30 per annum. All offices are open to candidates without additional fee.

There are two Scholarships open to University students, of 70 guineas and £50, particulars of which will be furnished by the Dean.

The St. George's Hospital Club has smoking and luncheon rooms on the Hospital premises and an athletic ground of 14½ acres at Wimbledon, and a football and tennis courts have been laid out.

Fees.—For first year, £21 or £26 5s., according to the course. For second and third years, £63 in two instalments. Students entering their names on the books before commencing the preliminary or intermediate subjects pay no entrance fee. Fees for clinical students : Entrance fee, 10 guineas ; annual composition fee, 30 guineas.

Guy's Hospital.—This hospital is situated on the South side of London Bridge, and contains 617 beds in constant occupation. There are special wards for ophthalmic and obstetric cases, eight beds in the latter being appropriated for difficult cases of labour. Some beds have also been set apart for diseases of the ear and throat, and an "isolation" ward for cases of infectious diseases arising in the hospital. Attached to the hospital is a large residential college with rooms for about sixty men, whilst for students who prefer to live in the suburbs, no other hospital is so conveniently placed, the railway accommodation being good and close at hand. There is a complete School of Dental Surgery at this Institution, which is recognised by the Royal College of Surgeons of England ; the facilities thus afforded of completing the whole course of dental study including the pupilage in mechanical dentistry within the walls of one hospital will be appreciated by those intending to practise dentistry.

Appointments.—Eight house surgeons, eight house physicians, sixteen out-patient officers, sixteen assistant house surgeons, twelve obstetric residents, two ophthalmic house surgeons, twenty-four clinical assistants, and ninety-six dressers are selected annually from the students according to merit, and without payment. There are also a large number of junior appointments, every part of the hospital practice being systematically employed for instruction.

Scholarships.—Open scholarships of £100 and £50 in classics, mathematics, and modern languages. Open scholarships of £120 and £60 in chemistry, physics, and biology, and an open scholarship of £50 for University students in two of the following subjects :—Anatomy, physiology, organic chemistry, zoology, physics. The following are the scholarships, prizes, and medals open to students of the hospital :—Junior prizes for general proficiency, £20, £15, £10 ; Hilton prize for dissection, £5 ; Michael Harris prize for anatomy, £10 ; Sands Cox scholarship for physiology, £15 ; Wooldridge prize for physiology, £10 ; Beaney prize in pathology, £34 ; Golding-Bird prize in bacteriology, gold medal and £20 ; Treasurer's gold medal in clinical medicine ; Treasurer's gold medal in clinical surgery ; Beaney studentship in materia medica (tenable for 3 years), annually £31 10s. ; Gull studentship in pathology (tenable for 3 or 5 years), annually £150. The Arthur Durham travelling scholarship of the value of £100, triennially ; Oldham Prize in Ophthalmology, £30 annually

Fees.—A new system for payment of composition fees has been instituted at this school. Particulars may be obtained on application to the Dean, Guy's Hospital, London Bridge, S.E.

King's College Hospital.—The hospital is now situated at Denmark Hill, S.E., and will open on October 1st with 220 beds. The student, who pays a composition fee for the whole medical curriculum, carries out his preliminary and intermediate medical studies at King's College, Strand, and enters the hospital when he has passed his examination in anatomy and physiology. The hospital contains special beds for diseases of women, children, eye, ear and throat cases. There are also dental, skin, X-ray, and photographic departments. There are well-equipped pathological laboratories, and the collection of pathological specimens has recently been moved from King's College to the hospital. The various athletic clubs, students' societies, and the Common Room are now under the management of the Clubs and Societies' Union.

Scholarships.—Four of £50 : one in arts and one in science, and two entrance scholarships for university students ; a senior scholarship for fifth year students, and many special and class prizes are open for competition amongst students.

Appointments.—Senior medical, surgical and obstetric tutorships, Sambrooke medical and surgical registrarships, tenable for two years, each £50 per annum. Resident hospital appointments—*viz.*, senior and junior house physicians, physician accoucheur's assistant and assistant house accoucheur, and three house surgeons with free board and residence at the hospital ; house anæsthetist ; and senior and junior clinical assistants in special departments every six months.

F.R.C.S. Examinations.—Special classes are arranged for the final F.R.C.S. examinations. Further particulars can be obtained post free from the Dean, Dr. H. Willoughby Lyle, or the Secretary, Clifton Kelway, Esq., King's College Hospital Medical School, Denmark Hill, S.E.

Fees.—The fees payable by full students for the Course of Advanced Studies, whether for the University Degrees or for the Examinations of the Conjoint Examining Board, are : 80 guineas if paid in one sum ; 82 guineas if paid in instalments, as follows : 10 guineas at entrance ; first payment, 40 guineas on entering the Hospital ; 32 guineas at commencement of second year.

These fees also include membership of the Hospital Clubs and Societies' Union for three years.

Composition fees have been arranged for the complete medical courses.

(1) University of London Course, including the Preliminary Scientific, Intermediate, and Final Course. Fee, 150 guineas.

(2) Conjoint Examining Board Course, including the courses for the 1st, 2nd, and 3rd examinations. Fee, 150 guineas.

The London Hospital.—This hospital is the largest in Great Britain, containing, as it does, 922 beds. It has, moreover, wards and a teaching staff for every special department in the domain of medicine; the scholarships and prizes are many and valuable.

Appointments.—The salaried appointments open to students are those of medical registrars three, surgical registrars three, obstetric registrars one, aural registrars two, medical, surgical and obstetric tutors; senior dressers to out-patients; clinical assistants in the medical, surgical, ophthalmic, aural, light and skin, orthopædic, and electrical departments. There are also six resident house physicians and nine resident house surgeons, two accoucheurs, seven receiving-room officers, two emergency officers, and three pathological assistants. Also unpaid clinical assistantships in the various special departments. In addition there are numerous assistantships and clerkships and dresserships in the various departments.

Scholarships and Prizes.—At Entrance: Price scholarships in science, £100; in anatomy and physiology, £52 10s.; entrance scholarship in science, £50; Epsom scholarship, £126; Buxton scholarships in arts, £31 10s. After Entrance: anatomy and physiology prize, £25; Letheby prizes, £25; prizes in clinical medicine, surgery and obstetrics, £20 each; Duckworth Nelson prize, £10; Hutchinson prize, £40; Sutton prize, £20; Sir Andrew Clark prize, £26; Anderson prizes, £9; dressers' prizes, £40; practical anatomy prizes, £10; Douro Hoare prize, £5; Wynne Baxter prize, £5 5s.

Special classes for the 1st and 2nd M.B.Lond., the primary and final Fellowship, and other examinations are held. Those for the final and primary F.R.C.S. commence on September 2nd.

Fees for Full Course.—Entrance Fee 20 guineas; annual Fee 30 guineas.

Special entries can be made either for single courses of lectures or for hospital practice. The Students' Hostel has recently been extended. Residential accommodation is obtainable at a very reasonable rate close by, or in the suburbs a few minutes' distant by train.

A Dental School is attached to the Hospital and provides the Course of Instruction for the Dental Diploma examinations.

Fuller particulars can be obtained of the Dean, Professor William Wright, M.B., D.Sc., F.R.C.S.

St. Mary's Hospital.—This Hospital is situated at Paddington, near the terminus of the Great Western Railway, and at present contains 301 beds, of which 31, in the Clarence Wing, are devoted to treatment by Therapeutic Inoculation. An additional Operating Theatre has recently been opened in this wing. The Inoculation Department, instituted in 1906, has greatly expanded, and occupies a series of rooms in the new wing of the Hospital.

The Department is under the personal supervision of Sir Almroth Wright, F.R.S.

During the past year a new Casualty Department has been opened, with increased accommodation.

The Athletic Ground is situated at Park Royal, Acton, within easy reach of the Medical School. This provides ample accommodation for the various athletic clubs, and possesses a good pavilion.

Appointments.—All clinical appointments in the hospital are free to students of the Medical School, and the resident medical officers are chosen by competitive examination. Six house physicians, six house surgeons, four obstetric officers, and two resident medical officers to the inoculation wards are appointed in each year, and receive board and residence in the Hospital. Four casualty house surgeons, and two resident anæsthetists are appointed annually, the term of office being six months. They receive a salary at the rate of £100 per annum with board and residence.

Scholarships, &c.—One scholarship in natural science of the value of £100, open to any gentleman who has not completed a winter session of study at a medical school. One scholarship of the value of £50 and one of the value of £26 5s., under the same conditions. Two scholarships, each of 50 guineas, open to University Students. The scholarships will be awarded by examination on September 22nd, 23rd, and 24th.

Fees.—Fee for attendance on the full five years' curriculum of hospital practice and all lectures, demonstrations, and special tutorial classes, £140, paid in one sum on entering the school; or in instalments, £145.

Students who have completed their examinations in anatomy and physiology at the Universities of Oxford, Cambridge, or other University, are admitted as perpetual pupils on payment of a fee of 65 guineas in one sum, or 70 guineas in two annual instalments.

Complete Curriculum.—The Medical School provides complete instruction for the various medical degrees and diplomas, including courses of preliminary scientific and intermediate subjects, which are recognised by the University of London as approved courses for internal students. Students may join in October, January, or April.

The Middlesex Hospital.—The Hospital and Medical School are centrally situated, and within a few minutes' walk of the principal tube and railway lines of the Metropolis.

The Hospital contains 440 beds, including special wards for cancer cases, maternity and gynæcological cases, and for diseases of the skin and eye. The cancer wing (containing 90 beds) and special investigation laboratories offer unrivalled opportunities for the study of cancer, both in its clinical and pathological aspects. In the electro-therapeutical department students obtain instruction in the treatment of lupus and cancer by the X-ray method.

The Hospital and Medical School are fully equipped for the theoretical and practical teaching of all the subjects of the medical curriculum, and for the Diplomas in Public Health. Ample laboratory and class-room accommodation is provided, and there is a clinical laboratory where every facility is given for original research. Special classes are held to prepare students for the intermediate examinations of the Universities, and for the primary and final examinations for the F.R.C.S. (England) Diploma. There is a residential college in the hospital for a limited number of students.

Hospital Appointments.—All appointments are made without fee of any kind, and the following appointments are made annually:—Six house physicians, eight house surgeons, two obstetric and gynæcological house surgeons, two casualty medical officers, two casualty surgical officers, and two resident officers to the special departments. Non-resident qualified clinical assistants are appointed to assist in the various out-patients' departments.

Scholarships, Prizes, etc.—Three entrance scholarships, value £100, £50, and £25, and a University Scholarship, value £50 (for Oxford and Cambridge students), are awarded annually in September. A Freer Lucas Scholarship, value £126, for students of Epsom College, is awarded annually on the nomination of the headmaster. There are also two Broderip Scholarships, value £60 and £40 respectively; the Lyell Gold Medal and Scholarship, value £55 5s.; the John Murray Medal and Scholarship, value £25 (awarded every third year); the Freeman Scholarship, value £30; the Hetley clinical prize, value £25; the Leopold Hudson prize, value 11 guineas; and the second year's exhibition, value 10 guineas. There are also numerous class prize examinations. In connection with the cancer investigation department, the following scholarships are awarded:—"Emden" Cancer Research Scholarship, value £100, tenable for three years; Richard Hollins Research Scholarship, value £105; Salters' Company Cancer Research Scholarship, value £100; and a Cancer Research Scholarship, value £60.

Fees—The composition fee for general students is 135 guineas; for London University students, 145 guineas; for those who have passed the first examination for medical degrees, 120 guineas; those who have completed their anatomical and physiological studies, 70 guineas. The fee for dental students is 54 guineas. The fees may be paid by instalments.

The Amalgamated Students' Club includes: The Medical Society, The Common Room Society, The Cricket and Football Clubs, etc. The Athletic Ground, which is eight acres in extent, is situated within easy access of the Hospital—at Park Royal. A subscription to the Amalgamated Students' Club is payable by all General and Dental Students.

The Winter Session 1913-14 opens on October 1st at 3 p.m. The Introductory Address will be delivered by W. Sampson Handley, M.D., M.S., F.R.C.S., after which the prizes will be presented by Sir Squire Bancroft.

St. Thomas's Hospital.— This Hospital, with medical school attached, is situated on the southern Embankment of the Thames, facing the Houses of Parliament, and contains 602 beds, in constant use. The school buildings, which are separated from the Hospital by a quadrangle, comprise numerous theatres, laboratories, and class rooms, which are well adapted for the modern teaching of large bodies of students in all subjects of the medical curriculum. There is a large library and reading-room, and a very complete museum and gymnasium.

Appointments are open to all students. A resident assistant physician and a resident assistant surgeon are appointed annually at a salary of £150 with board and lodging. Four hospital registrars, two at an annual salary of £100 each, and two at £50 each, are appointed yearly. The tenure of these offices may be renewed for a term not exceeding two years. Four resident house physicians, four house surgeons, eight casualty officers, two resident obstetric house physicians, and two ophthalmic house surgeons are appointed each six months, also out-patient officers, and clinical assistants in the special departments.

Scholarships, Prizes, etc.—Five entrance scholarships are offered for competition in July and September—*viz.*, one of £150 and one of £60 in chemistry, physics, and biology at the commencement of the second year; one of £50 open to University students who have passed in anatomy and physiology, for a medical degree in any of the Universities of the United Kingdom, and have not entered as students in any London Medical school, and two scholarships in arts giving free tuition for the first year of curriculum. Numerous scholarships, prizes, and medals are open to competition throughout the whole career of a student, including a Fellowship of £100 given by the Salters' Company for research in pharmacology, and the Louis Jenner research scholarship, £60, for pathological research.

Special courses of instruction for the First Professional Examination and Intermed., M.B.Lond., for the Oxford and Cambridge examinations, and for the Primary and Final F.R.C.S. are held throughout the year.

The prospectus of the school may be obtained on application to Mr. G. Q. Roberts, Secretary of the Medical School.

Fees.—A system for payment of composition fees is in operation. Full details may be obtained of the Secretary.

University College Hospital and Medical School.—*Entrance.*—A student may enter the school as soon as he has passed the University of London Matriculation Examination, or one of the other qualifying preliminary examinations. In this case he will pursue his preliminary and intermediate studies at University College, and his final medical studies at University College Hospital Medical School. The student who has completed his preliminary and intermediate medical studies elsewhere, may enter the University College Hospital Medical School for his final medical studies only. Qualified medical men and others who can produce evidence of sufficient qualifications may be admitted to special departments for the purposes of research, or to hospital practice for certain definite periods.

University College Hospital now accommodates 305 in-patients, and possesses extensive out-patient and special departments.

Thirty-eight clinical appointments, eighteen of which are resident, are filled up by competition during the year, and are open to students at the hospital without extra fee.

The new medical school provides for lectures, demonstrations and practical work in all the final subjects of the medical curriculum. There are three lecture demonstration theatres for the teaching of morbid anatomy, bacteriology, and chemical pathology; also rooms equipped for the teaching of operative surgery and surgical anatomy, and two large lecture theatres.

The Medical Society, founded in 1828 for promoting the study of medical and surgical sciences amongst students, and for social intercourse, has rooms set apart for reading and recreation, and there is a large gymnasium with baths attached in the school buildings.

Scholarships, &c. — Entrance scholarship of 135 guineas, and two of 80 guineas each, the subjects being anatomy and physiology; the Graham scholarship in pathology, £200 per annum; the Atkinson-Morley surgical scholarship of £45 a year, tenable for three years; the Atchison scholarship, value £55, tenable for two years; Filliter exhibition for proficiency in pathological anatomy, value £30; Erichsen prize, operating case, value £10 10s., awarded for practical surgery; Fellowes gold and silver medals, the Liston gold medals, Alexander Bruce gold medal, Tuke medals for pathology, and other prizes, as well as certificates of honour, are awarded after competitive examinations in particular branches of study.

Composition Fees.—The Preliminary Scientific Course at University College, 26 guineas; Intermediate Course at University College, 58 guineas; final M.B. Course at University College Hospital Medical School, 80 guineas if paid in one sum, or 82 guineas paid in two instalments of 50 and 32 guineas.

Westminster Hospital.—This hospital is conveniently situated, facing the Abbey, and is readily accessible from all parts of the Metropolis. It contains 205 beds for general cases, and all the special departments. New school buildings have been erected close by, which afford accommodation for 150 students. The class rooms, museum, laboratories, and lecture theatre are excellent samples of modern erections, affording ample scope for study.

Appointments.—Medical and surgical registrars, each £50 per annum; two house physicians, three house surgeons, one assistant house physician, one assistant house surgeon, and a resident obstetric assistant. These officers, except the two first named, are all boarded free of expense. Qualified students are appointed to be clinical assistants in the various departments.

Scholarships, &c.—(*a*) Winter Session—The Guthrie scholarship, £60; subjects, Latin, mathematics, English, and either Greek, French or German. Two University scholarships, £50 each; subjects, anatomy and physiology. Natural science scholarship, £60; subjects, same as for Preliminary Science of University of London. Natural science scholarship, £30; subjects, chemistry and physics. (*b*) Summer Session.—Governors' scholarship in Chemistry and Physics, £40, Two University scholarships as for Winter Session. (*c*) Prizes to be competed for by unqualified men. Chadwick prize in Medicine and Surgery, 20 guineas, for students of any year not exceeding fifth. Bird medal and prize, in Obstetric Medicine, £14, for students who have completed fourth winter session. Sturges prize in Clinical Medicine, about £6, clinical surgery prize, £5. Abrahams prize in Clinical Pathology, 5 guineas. And class prizes in the various subjects.

Fees.—(*a*) The Annual Composition Fee is 25 guineas. This includes the subscriptions for membership of the Clubs' Union. (*b*) For shorter periods or for single courses the fees may be learned on application to the Dean. Fees for dental students, payable in one sum on entrance, 50 guineas, or in two instalments of £27 10s. each.

London (Royal Free Hospital) School of Medicine for Women.—The school is situated in Hunter Street, and the Royal Free Hospital is in Gray's Inn Road, close by. Students are prepared for the London University examinations and for the examinations of other Universities. A course of study is also arranged for the work required by the Royal Colleges of England, the Conjoint Colleges of Scotland and the Society of Apothecaries of London. The Royal Free Hospital contains 165 beds available for clinical study; and there is a large out-patient and casualty department. In addition to the ordinary systematic lectures at the school, clinical lectures are given at the hospital in Medicine, Surgery, Obstetrics, Ophthalmology, Dermatology, Rhinology, and Laryngology. Students hold clerkships and dresserships in each department.

Appointments.—House physicians, house surgeons, and a senior and junior resident obstetric assistant are appointed yearly. There are also non-resident appointments, including the anæsthetists and assistant anæsthetist, assistant and clinical pathologists, medical and surgical registrars, curator of museum and clinical assistants.

Fees.—The fee for the University of London course and the course for the Royal Colleges of England is £160 in one sum, or £170 if paid in five instalments. The fee for the course for the Scotch Colleges or Society of Apothecaries, including Elementary Science, is £140 in one sum, or £150 in four annual instalments. Particulars as to scholarships, etc., can be obtained from the Secretary and Warden, Miss L. M. Brooks, 8 Hunter Street, W.C.

London School of Tropical Medicine.—The next session of the School commences on the 1st of October. The past year has been one of the most successful on record, and for the session ending in July 64 students entered. The course is so arranged as to equip men for the Cambridge Diploma in Tropical Medicine and Hygiene, the London Diploma in Diseases and Hygiene of the Tropics, as well as for the London University M.D. Special facilities are now afforded for advanced students in entomology, helminthology and protozoology. A new course in Tropical Sanitation and Hygiene will be started in the winter session, and the new resident accommodation for students will be made available at the same time. The Wandsworth Scholarship of £350 and the Hon. Edward John Stanley Memorial Scholarship of £50 are awarded annually. The School provides three sessions each year.

INTRA-ACADEMICAL INSTITUTIONS IN LONDON.

The Royal Dental Hospital.—The teaching and hospital practice at this institution (situated in Leicester Square) are recognised by the various examining bodies. The new hospital and school, which was opened seven years ago, is complete in every detail with modern appliances. The clinic of the hospital is unrivalled, no fewer than 105,000 operations being performed in one year. The following scholarships and prizes are open to all full-term students:—Entrance scholarships, of the value of £50 and £25, being awarded in October. Subjects: Chemistry and Physics, Saunders scholarship, of the value of £20, awarded to the student obtaining the highest aggregate number of marks in a special examination of the subjects of the final examination for the Dental half of the L.D.S. A scholarship of £25, the subjects being Dental Mechanics and Metallurgy. There is also an Entrance Scholarship of £25 open to those who have studied "Dental Mechanics" under the tuition of a private practitioner. Storer-Bennet Research Scholarship, of the value of £50, awarded once in three years; the Alfred Woodhouse Scholarship of £35, and the Robert Woodhouse Prize of the value of £10, for practical dental surgery. Class prizes are awarded by the various lecturers. Provision is made for teaching Dental Mechanics, as required by the Royal College of Surgeons, the pupils being under the guidance of the staff of dental surgeons assisted by specially appointed demonstrators. The school contains an excellent library and a well-arranged museum.

Fees.—For the two years' hospital practice and lectures as required by the Royal College of Surgeons of England, the fee is £53 3s. in one instalment, or £55 13s. in two yearly instalments. The fee for the complete curriculum—namely, two years' instruction in Dental Mechanics and two years' hospital practice and lectures, is £150 if paid in one sum, or 150 guineas if paid in three instalments of 50 guineas each. For one year's instruction in Dental Mechanics the fee is 50 guineas. For one year's hospital practice, £21. For the courses in Chemistry and Physics for the Preliminary Science Examination, £10 10s. The necessary course of two years at a general hospital can be taken simultaneously with that at the Royal Dental Hospital. Further particulars can be obtained on application to the Dean.

National Dental Hospital (The Dental Department of University College Hospital).—This institution is situated in Great Portland Street, and excellent teaching facilities and hospital practice are here obtainable, special demonstrations being given by members of the staff. There are also a mechanical laboratory, bacteriological laboratory, X-Rays Department, museum, students' common room, a metallurgical laboratory, extraction and stopping rooms, lecture hall, regulations room, &c., all lighted by electricity, and warmed and ventilated after the most approved requirements; in fact, this institution may be pronounced a model dental department of a general hospital and school. The winter session commences at the same time as at the medical school, on October 1st. The medical tutor holds special classes before each college examination. The prizes include two entrance exhibitions, value £40 and £20, and the Rymer prize of £5 5s., the examinations for which are held in May and October. The fee for two years' hospital practice required by the full curriculum, including lectures, is £200.

For qualified medical men the two years' training in dental mechanics, required by the R.C.S. Curriculum, can be taken in the Mechanical Laboratory, and there is a "Composition Fee" including all the dental subjects of the curriculum of £120.

Medical students are admitted to the practice of the following Metropolitan general hospitals to which no medical school is attached, but each contains over 100 beds. Detailed particulars will be supplied on application to the various secretaries.

Prince of Wales's Hospital, Tottenham.—This hospital contains medical and surgical wards and a ward for children, having in all 125 beds, with a very large out-patient department. There are special departments for gynæcological cases, diseases of the eye, ear, throat and nose, medical electricity and radiography, and skin diseases. It is authorised by the University of London to give certificates of post-graduate study for the M.D. and M.S. degrees. (Post-graduates of both sexes are admitted to the practice of this Hospital.)

Great Northern Central Hospital, Holloway Road, N.—This institution has been greatly enlarged, contains 182 beds, cases in various special departments are treated, and the hospital is now recognised for study during the fifth year by the Conjoint Board. The Pathological Department has been extended and a Director of Clinical Pathology appointed. The practice of the hospital is open to practitioners and senior students, and clinical and pathological assistants are appointed in the wards and out-patient departments, as in the larger general hospitals.

Bethlem Royal Hospital.—In this Royal institution only cases of lunacy are received, and students intending to pursue this special branch have the best possible opportunities afforded here. The hospital contains 300 beds, and two resident house physicians who have recently obtained their diplomas to practise medicine and surgery are elected every six months, and are provided with apartments, complete board, attendance, washing, and an honorarium of 25 guineas per quarter. The students of certain specified London medical schools receive clinical instruction in the wards of the hospital, and qualified practitioners may attend for a period of three months on payment of a fee. Post-graduate lectures are also given.

National Hospital for Epilepsy and other Diseases of the Nervous System, Queen Square, W.C., contains, with its country branch, 200 beds and cots. It is recognised by the Conjoint Board where part of the fifth year of study may be devoted to clinical work. Clinical clerks are appointed to the physicians for out-patients, and courses of lectures and clinical demonstrations are given each year.

West End Hospital for Diseases of the Nervous System, Paralysis, and Epilepsy, Welbeck Street, W.—Graduates in medicine and senior students may attend demonstrations in the Out-patient Department. No fees are charged. The Savill Prize and Medal is awarded to the student who makes the best *viva-voce* examination and presents the best thesis after attending at least 25 demonstrations.

London Temperance Hospital.—This Institution is situated in the Hampstead Road, and contains 100 beds, and is conducted, as its name implies, on non-alcoholic principles by an excellent staff. The medical and surgical practice is open to students and practitioners. Appointments (vacancies for which are advertised in the medical journals): Surgical and medical registrars, resident medical officer, and one assistant resident medical officer.

Metropolitan Hospital, Kingsland, N.E.—This was until recently known as the Metropolitan Free Hospital, is situated in the north-eastern district of the Metropolis, and contains 123 beds, besides 18 beds at a convalescent home. It is a general hospital, with a large medical and surgical staff, in which various special departments for the treatment of diseases of the eye, throat, ear, diseases of women, etc. will be found.

SPECIAL HOSPITALS.

Hospitals for Consumption.

Hospital for Consumption and Diseases of the Chest, Brompton.—The largest institution for the treatment of affections of the chest in the United Kingdom, there being 333 beds in the two buildings. There are six house physicians who reside in the hospital, each for a period of six months. Lectures and demonstrations are given by members of the medical staff on Wednesdays at four o'clock, save during the vacations. Terms, £2 2s. for three months; £5 5s. perpetual. A special course of instruction in the diagnosis and treatment of pulmonary tuberculosis will be held in November. This hospital is recognised by the Conjoint Board, the University of London, and the Apothecaries' Society.

Mount Vernon Hospital, Hampstead and Northwood.—This institution, formerly called the North London Consumption Hospital, now carries on its work at Hampstead with 120 beds, and at Northwood with 106 additional beds, where treatment is carried out on the most modern lines, including the "open air" and other systems. Students are admitted to the practice of the hospital under certain conditions, and post-graduate courses are regularly delivered during the year.

City of London Hospital for Diseases of the Chest, Victoria Park.—This is a large and well-equipped hospital at the East End, containing 170 beds. Clinical lectures and demonstrations are given by the members of an exceptionally experienced staff. Fee for three months' attendance on hospital practice, 2 guineas; six months, 3 guineas.

Royal Hospital for Diseases of the Chest, City Road.—This hospital was established 100 years ago, and has been from time to time enlarged by the addition of a very complete out-patients' department, and also by the erection of a new wing, which provides accommodation for 80 in-patients.

Throat and Ear Hospitals.

Metropolitan Ear, Nose, and Throat Hospital.—This hospital was founded in 1838, and is situated in Fitzroy Square. The out-patient department is opened daily at 2.30 p.m. to practitioners and students desirous of acquiring clinical instruction and technical knowledge. Operations are performed on in-patients on Tuesdays, Wednesdays, Thursdays and Fridays at 10 a.m. Fee for one month's attendance at the hospital one guinea, and for three months two guineas.

Hospital for Diseases of the Throat, Golden Square, W.—This hospital contains 48 beds. Clinical instruction is given daily in the Out-patient Department on diseases of the nose, throat, and ear, and systematic courses of lectures are given during the winter session. There are nine clinics weekly, and an annual out-patient attendance of nearly 60,000. Major and minor operations daily (Mondays excepted) in different theatres. Thirty-six junior clinical assistants are appointed from among the students to assist the surgeons. Students are admitted to the practice of the hospital at the following fees:—Three months, £5 5s.; six months, £7 7s.; longer periods, £10 10s. Further details can be had by applying to the Hon. Med. Secretary.

Central London Throat and Ear Hospital.—This hospital contains accommodation for 30 in-patients. It has a very extensive out-patient department (over 50,000 attendances yearly), which is open daily to all medical practitioners and students, for the purpose of clinical demonstration and instruction. Courses of practical teaching are held twice weekly by members of the staff, which are open to qualified practitioners and advanced students. Each course is of about seven weeks' duration, and includes hospital attendance for that period.

Operations are performed daily (Saturday excepted) at 2 p.m. Special attention is devoted to scientific work in the newly-equipped laboratory. Full particulars will be supplied on application to the Dean.

Women and Children.

Hospital for Sick Children, Great Ormond Street, Bloomsbury, and Cromwell House, Highgate. This is the largest Children's Hospital in the United Kingdom, and contains 240 beds.

The practice of the Hospital is open to qualified medical men, and to students who have completed four years of medical study, the Hospital having been recognised by the Conjoint Board of England as a place where six months of the fifth year may be spent in clinical work. There are special ophthalmic, aural, dental, and electrical departments. There is also a Museum and Library in connection with the School. —Fee for three months' general hospital attendance, £5 5s.; perpetual, £10 10s.; £1 1s. for students satisfactorily undertaking clinical clerkships for not less than three months. Facilities are afforded for obtaining theoretical and practical instruction in Clinical Pathology and Bacteriology by daily attendance in the Pathological Laboratories, the fees for which are: For one month, £3 3s.; three months, £6 6s. For tickets and further information, apply to the Secretary, by letter, or by calling at the Hospital.

Queen Charlotte's Lying-in Hospital, Marylebone Road, N.W.—Qualified medical practitioners and medical students are admitted to the practice of this hospital. Certificates of attendance are recognised by all universities, colleges and licensing bodies. Fee for the course of four weeks, £8 8s. Students are accommodated at the new Residential College (5 Cosway Street) opposite the hospital.

Arrangements have also been made for the preliminary instruction in midwifery now required by the General Medical Council. This will include:—(1) Practical instruction in the methods of examination of pregnant women; (2) delivery of women in labour under the direct supervision of a medical officer of the hospital; (3) practical instruction in the treatment of the mother and child during the puerperium, including clinics held four times weekly by the visiting medical staff. Fee for this special course will be £5 5s. per month.

East London Hospital for Children, Shadwell.—This institution was founded about sixty years ago in one of the poorest quarters of the East End of London and contains 124 beds, with special departments for electric treatment. ophthalmic and dental surgery, etc.

Royal Waterloo Hospital for Children and Women.—This important institution situated in South London, has been rebuilt and appointed on completely modern lines, and now provides 90 beds.

The Samaritan Free Hospital for Women, Marylebone Road, N.W., has 56 beds, and offers excellent opportunities to qualified medical men for clinical study and training in the details of operative gynæcology. Fee: Three months, £3 3s. The success of the staff in this department has gained for them a European reputation. There are 51 beds.

The Hospital for Women, Soho Square.—The hospital contains 67 beds. In connection with this institution there is now an organised school of gynæcology open to qualified medical men and to students after their third year. Clinical assistants to the physicians and surgeons in the in-patient and out-patient departments are appointed every three months. Fee for the three months' course, and certificate, £8 8s.

Chelsea Hospital for Women, Fulham.—This institution contains 50 beds, and is served by a staff of considerable eminence. In connection with it there is a Convalescent Home at St. Leonards, in which 22 additional beds are at the disposal of the authorities.

Eye Hospitals.

Royal Eye Hospital, St. George's Circus, Southwark, S.E.—There are 40 beds and two cots at this Institution. Lectures, demonstrations, instruction in refraction work, and demonstrations on the specimens in the Museum are given throughout the year by the teaching staff. Patients are seen in the out-patient department and operations are performed in the theatres daily, morning and afternoon. There are annually upwards of 21,000 new out-patients attending the Hospital. Fees: For three months' practice and tuition, £3 3s.; perpetual, £5 5s. Further particulars of the Dean.

Royal Westminster Ophthalmic Hospital, adjoins Charing Cross Hospital in King William Street, It has about 40 beds and a very large out-patient *clinique*. The lectures and demonstrations are arranged with special reference to the requirements of practitioners and senior students. Fee, six months, £3 3s.; perpetual, £5 5s.

Royal London Ophthalmic Hospital, formerly in Moorfields, and recently rebuilt in the City Road, is the largest hospital devoted to this specialty in Great Britain, and contains 138 beds. Students and practitioners are admitted to the practice daily at 9 o'clock. Operations, 10 o'clock and after. Fee for six months, £3 3s.; perpetual, £5 5s. Further particulars of the Secretary.

Royal Eye Hospital, St. George's Circus, Southwark.—There are 40 beds and two cots. Fees, £2 2s. for three months, £3 3s. for six months, and £5 5s., perpetual. Courses are held on ophthalmoscopy, refraction, and diseases of the eye; fee, £1 1s. for each course, but perpetual students may attend each course once without extra fee. Pathology class, £1 1s. extra to cover cost of materials.

Central London Ophthalmic Hospital.—This hospital is situate in Judd Street, St. Pancras, has 26 beds and a large out-patient *clinique*. The post of clinical assistant is open to both men and women, who must be duly qualified and registered practitioners. During the winter session commencing in October lectures and demonstrations are given in all the branches of ophthalmology. A course lasting three weeks, comprising about forty lectures, will commence on September 15th, embracing all the branches of Ophthalmology—viz., Anatomy, External Diseases, Medical Ophthalmology, Use of the Ophthalmoscope, Refraction, Operative Surgery, Pathology, Bacteriology, and X-Ray. The Classes will be given by various members of the Staff, and are limited to a certain number of Students. Early application is therefore desirable. Syllabus and further particulars of the Dean of the School.

Skin Hospitals.

St. John's Hospital for Diseases of the Skin.—Out-patient department, 49 Leicester Square; In-patient department, 262 Uxbridge Road, W. This hospital has a well-equipped in-patient department, with 40 beds. It has a School of Dermatology at 49 Leicester Square, which is conducted by the medical staff of the hospital. During the past year the free course of Chesterfield Lectures have been well attended. The Out-patient Department has recently been rebuilt at a cost of £10,000, and contains a spacious laboratory and special electrical department which can be seen in operation every afternoon except Saturday. Special Courses in Pathology and Bacteriology can be arranged for. Clinical demonstrations are given every day at 2 p.m., on Selected Cases.

The Western Skin Hospital.—This is one of the oldest institutions of the kind in the metropolis, and was started as long ago as 1851. It has recently been removed to larger premises in the Hampstead Road, and the practice of the hospital is open to students and practitioners, who have the opportunity of seeing daily a large number of out-patients.

The Hospital for Diseases of the Skin, Stamford Street, Blackfriars.—This was the first hospital to be established for the treatment of cutaneous disorders in London. It has an extensive out-patient department, which is open to qualified practitioners. The hospital is shortly to be rebuilt.

METROPOLITAN POST-GRADUATE INSTITUTIONS.

Medical Graduates' College and Polyclinic.—This institution affords to medical practitioners special facilities for acquiring technical skill and advancing their medical and scientific knowledge. The building, which is large and commodious, is situated in Chenies Street, Gower Street, and contains lecture and consulting rooms, pathological and clinical laboratories, Röntgen ray room, an ophthalmoscope room, a library and museum, and reading and smoking rooms. *Cliniques*, at which patients are shown, are given every day of the week except Saturday, at 4 p.m. Lectures on Medicine, Surgery, and other allied subjects are delivered on Mondays, Tuesdays, Wednesdays, and Thursdays at 5.15 p.m. Four sessions of practical classes, each lasting six weeks, and two vacation sessions each of three weeks' duration, are held during the year, the subjects taught comprising anæsthetics, clinical examination of nervous system, clinical microscopy, clinical methods and physical diagnosis, clinical examination of stomach contents, cystoscopy, electro-therapeutics, gynæcology, intestinal surgery, laryngology, massage and medical electricity, ophthalmology, otology, orthopædics, rhinology, Röntgen rays, sigmoidoscopy, surgical anatomy and diagnosis. There are, in addition, extra-mural classes in operative surgery and practical anatomy with dissecting. Special tutorial classes in medicine, surgery, midwifery, and pathology for gentlemen reading for the higher qualifications have recently been instituted, and are conducted regularly throughout the year. The annual subscription for medical practitioners of either sex is One Guinea. Full information may be obtained from the Medical Superintendent, 22 Chenies Street, Gower Street, W.C.

West London Post-Graduate College.—The West London Hospital, Hammersmith, contains 160 beds; the post-graduate course was started in 1895. Instruction is given in the out-patient department daily at 2.15 p.m. by the assistant physicians and assistant surgeons. The physicians and surgeons attend daily at 2.30 p.m., when post-graduates can accompany them in their visits to the wards. Operations are performed daily at 2.30 p.m. Demonstrations are held every morning and there are lectures every evening at 5 p.m. (Saturdays excepted). Special classes are held in bacteriology, vaccine therapy, diseases of the eye, throat, X-rays, anæsthetics, intestinal surgery, tropical medicine, cystoscopy, venereal disease, operative surgery, &c.

Fees.—The fee for the hospital practice, including all the ordinary lectures and demonstrations, is £1 1s. for one week; £3 3s. for one month; £6 6s. for three months; £10 10s. for six months; £15 15s. for one year, and £30 for a life ticket. A course of attendance on either the medical or surgical practice alone may be taken out for the fee of £4 4s. for three months. The fee for three months' attendance in any one special department, other than medicine or surgery, is £3 3s. A prospectus containing full particulars will be forwarded on application to Mr. D. Armour, Dean.

West London Hospital, Hammersmith Road, W.—(Only qualified medical men are admitted to the practice of this Hospital). This hospital contains 160 beds, and has an extensive out-patient department. Three house surgeons and three house physicians are selected every six months. There are special departments for diseases of the throat, nose and ear, skin, women and children, and deformities. Electrical and X-ray departments have also been added.

North-East London Post-Graduate College.—This post-graduate school is established in connection with the Prince of Wales's General Hospital, Tottenham, N., which is recognised by the University of London as a place of post-graduate study for the M.D. and M.S. degrees, and by the Admiralty and the India Office for purposes of study leave. Facilities are here afforded to qualified medical practitioners for taking part in the work of an active general hospital, and for attending demonstrations in various branches of medicine, surgery, and gynæcology, with opportunities for clinical instruction in diseases of the eye, ear, throat, nose, skin, in fevers, psychological medicine, the administration of anæsthetics, radiography and dentistry. Cliniques, lectures and demonstrations are given by members of the teaching staff in the lecture room, in the wards, in the various out-patient departments, and in certain affiliated institutions. Operations are performed every afternoon of the week, except Saturday. Special classes, the attendance at which is limited, are arranged in gynæcology, the surgical diseases of children, including orthopædic surgery, diseases of the throat, nose and ear, diagnosis of diseases of the nervous system, ophthalmoscopy and refraction, clinical pathology, diseases of the skin, abdominal surgery, radiography, bacteriology (which is accepted by the University of Cambridge for the D.P.H. diploma) vaccine therapy, pathological chemistry and medical electricity. The fee for a three months' course of study, which may be begun at any time, in any single department, is one guinea. A fee of three guineas admits to the whole practice of the hospital for a similar term (one month, 2 guineas), and a perpetual ticket for the practice of the hospital may be obtained on payment of a fee of 10 guineas. The opening lecture of the Winter Session will be given by Sir Arbuthnot Lane, Bart., towards the end of October. Additional information with a syllabus of lectures, demonstrations, and special classes, may be obtained from the Dean of the Post-Graduate College, Dr. A. J. Whiting, at the Hospital, or at 142 Harley Street, W.

London School of Clinical Medicine is entirely reserved for qualified practitioners, no unqualified students being allowed to attend its cliniques and classes. The school is held at the Seamen's Hospital, Greenwich, with which are affiliated for teaching purposes the Royal Waterloo Hospital for Children and Women, the Bethlem Hospital, and the General Lying-In Hospital, all within the South-Eastern district. The Dreadnought Hospital is situated at Greenwich, and contains 250 beds, which are continually occupied by patients suffering from every variety of disease. It provides annually for 2,000 in-patients and 19,000 out-patients. The out-patient department at the Dreadnought Hospital is supplemented by the Society's dispensaries in the East India Dock Road, and at Gravesend, at which the present annual attendance is approximately 4,000 patients. Out-patient cliniques are held in surgery, medicine, and the special departments every morning; whilst in the afternoons ward cliniques are given in medicine, in surgery, and in one of the special departments. Operations are performed daily. The fee for attendance on the ordinary practice of the hospital provides for admission to the wards, operating-theatres, post-mortem rooms, out-patient rooms, and cliniques. Most of the practical clinical classes, such as those in laryngology, ophthalmology and dermatology are included in the fee for Clinical Teaching, but may be omitted if desired. Other practical classes, such as operative surgery and pathology, are arranged each session. The hospital is reached from London in a few minutes by rail and electric tramway.

The following are some of the principal provincial hospitals having the greatest number of beds, to which students are admitted, where clinical instruction can be obtained, but to which there is no medical school attached :—

Bath Royal United Hospital, Bath.—This hospital contains 130 beds and possesses an extensive library. Considerable alterations and re-arrangements are contemplated in the out-patient department during the coming year, and also a complete installation of heating by hot water.

Royal Berkshire Hospital.—The town of Reading, in which this hospital is situated, has a very large working-class population, and excellent opportunities for clinical instruction in the wards and extensive out-patient department are afforded here. This hospital, which contains 188 beds, has been recently enlarged, and there is also a splendid library, in which the Reading Pathological Society holds its meetings.

Bradford Infirmary.—The hospital contains 210 beds. Non-resident pupils are received and abundance of clinical material is obtainable in all the special departments of Medicine and Surgery. One year's attendance is recognised by the Examining Boards. Fee, perpetual, £10 10s.

Royal Devon and Exeter Hospital, Exeter.—This hospital contains 200 beds (including special children's wards), and numbers on its staff several well-known names; has a good library. Attendance on the practice of this hospital qualifies for all the examining boards, and students can attend Midwifery on application to the House Surgeon. Arrangements may also be made by which practitioners may have the use of the museum and library, and other facilities.

Leicester Infirmary is duly recognised by the various examining bodies, and contains 230 beds, and at the Children's Hospital in connection, 42. A new wing containing 100 beds has recently been added, together with a new Nurses' Home.

Liverpool.—The principal hospitals in this city, four in number, now form a combination for teaching purposes, in connection with the Liverpool University. These are referred to in another column, under "Universities," and are the Liverpool Northern Hospital, the Royal Southern Hospital, the Royal Infirmary, the Stanley Hospital, together with five special hospitals, the whole containing a total of 1,127 beds.

The Liverpool Skin Hospital and Extra-Mural School of Dermatology, in Pembroke Place, has eight beds and an Out-patient Department where over two thousand different patients are registered annually, and is open to Senior Students and Practitioners of Medicine. There is an excellently equipped "Light" Department where instruction is given in X-Ray and Finsen Light Therapy, and attached to the Hospital is a Museum of Dermatology. Terms for private instruction, 10 guineas per month. Dr. Stopford Taylor will give a course of twelve demonstrations, commencing September 14th. Fee for the course, 1½ guineas.

Norfolk and Norwich Hospital.—This hospital is recognised by the Colleges, and contains 230 beds. Fees, £10 10s. for six months, £15 15s. for twelve months' medical and surgical practice. Pupils, resident and non-resident, are admitted.

North Staffordshire Infirmary, Hartshill, Stoke-on-Trent.—This institution is built on the pavilion plan, and has accommodation for 216 patients, including children's wards, women's wards, and a special department for the treatment of diseases of the eye, so that there are excellent facilities here for acquiring a practical knowledge of the profession.

Nottingham General Hospital.—As a large commercial and industrial centre, Nottingham boasts of a large general hospital and several special institutions. The General Hospital contains 254 beds, and is staffed by several well-known physicians and surgeons. The practice is open to qualified members of the profession, and house appointments obtained hereat yield valuable material for study, especially in the direction of accidental injuries.

The Royal Sussex County Hospital, Brighton.—This hospital possesses about 196 beds, as well as a large out-patient department, and a well-appointed clinical research and bacteriological department. Hospital practice may be gained here for a period not exceeding two years on payment in advance of a fee of 20 guineas. There is also an excellent library attached.

Wolverhampton and Staffordshire Hospital.—This is one of the largest hospitals in the Midlands, and contains 212 beds. Situated as it is in the centre of the great coal and iron industries, it affords ample material for clinical study, and as the Hospital is recognised by the Royal Colleges, and has an excellent staff, its position is excellent.

Ireland.

THE IRISH MEDICAL SYSTEM.

The system of medical teaching in Ireland differs from that in England in important particulars. In London each clinical hospital has its attached medical school, fully equipped, which educates the students of that hospital and very seldom those of any other. In Dublin, on the contrary, the hospitals and schools are entirely separate (except that Sir Patrick Dun's Hospital is officially connected with Trinity College), and a student of any school is free to enter for the whole or any part of his course at any school or hospital he pleases.

COST OF MEDICAL EDUCATION IN IRELAND.

The cost of obtaining a medical qualification depends to some extent on the qualification sought. In this connection the following tables may be of use to the prospective student:—

COST OF MEDICAL EDUCATION.

School of Physic, Dub. Univ. ..	£122 17s.
Royal College of Surgeons School	£124 19s.
University Colleges	About £125.
Queen's University, Belfast ..	£105

COST OF DIPLOMAS OR DEGREES.

Dublin University	£27 (to this must be added £83 4s., the cost of obtaining an Arts degree).
National University	£25.
Queen's University, Belfast ..	£19 19s.
Conjoint Royal Colleges ..	£42.
Apothecaries' Hall	£22 1s.

Thus, the absolute payment will amount to somewhere between £125 and £233 1s. according to the course chosen. For the Conjoint Colleges the entire cost is £166 19s., taking the minimum mode of payment. So that, assuming that extras or voluntary costs are incurred the total will vary, say, from £170 to £200. "Grinding," although not officially recognised, occupies a position similar to that of the extra-mural instruction of other schools. Its cost must be reckoned among the expenses of the course, for, while not essential, it has become customary for almost all students to obtain aid in their studies in this way. As a rule, this private instruction costs about £5 5s. for each of the four examinations.

The above sum, or something like it, may be expended by the student or his parent in paying for lectures, &c., and examination fees as they fall due, and there is no difficulty in obtaining the needful information for his guidance if he likes to pay for his course in this fashion.

All the schools require fees for each course to be paid in advance.

Women are admitted to all the courses, degrees, and licences on the same terms as men.

DATE OF ENTRY.

The entry of names and commencement of study in Ireland is *supposed* to date from the 1st of October in each year, but entries are accepted up to the end of that month, or in some schools even later. It should be remembered that no credit is given for studies or attendance until the entry is regularly made. The student must attend three-fourths of the lectures delivered, and if he loses any time at the beginning he must make up for it afterwards by constant attendance.

The student begins work by attending a recognised medical school each morning at ten o'clock, and occupying his day, to five p.m., between lectures and dissections. His vacations are a fortnight at Christmas and a fortnight at Easter, and the academic year ends at the end of June.

PRELIMINARY EXAMINATIONS.

The first act of the student is to pass a preliminary examination, without which he cannot get credit for any medical studies pursued. The next is to commence medical study. This he does by entering for lectures at a medical school. From the school registrar he gets a form of certificate, and his third act is to take it or send it to the Branch Medical Council, 35 Dawson Street, Dublin, unless, as is usually the case, this duty is undertaken for him by the school registrar. He is thereupon placed upon the Register of Medical Students (without fee), and his period of study counts from that date. He must register at the earliest possible moment, or he may lose credit for his work.

The only preliminary examination held specially for medical students is that held conjointly by the Royal Colleges of Physicians and Surgeons, but other examinations—*e.g.*, the public entrance at Trinity College, the matriculation of the National and Queen's Universities, the Intermediate Examination passes in the required subjects, and certain other examinations recognised by the General Medical Council, are accepted as equivalent.

The subjects of examination as prescribed by the General Medical Council are as follows:—1. English language, including a specified author, dictation, grammar, and composition; also parsing and analysis from a book specified. 2. Latin, including grammar, translation from specified authors, and translation of easy passages not taken from such authors. 3. Elements of mathematics, comprising (*a*) arithmetic, including vulgar and decimal fractions; (*b*) algebra, including simple equations; (*c*) geometry, Euclid, Books I., II., and III., with easy deductions. 4. One of the following optional subjects:—(*a*) Greek, (*b*) French, (*c*) German.

THE IRISH LICENSING BODIES.

The Medical Licensing Bodies of Ireland are five in number, and, as a rule, students will gravitate into one or other of six classes:—*a.* Those who enter Trinity College, and take a full graduation in Arts in addition to their professional degrees. *b.* Those who take the conjoint licence of the Royal Colleges of Physicians and Surgeons. *c.* Those who take their qualifications at the National University of Ireland, where graduation in Arts is not necessary. *d.* Those who enter Queen's University, Belfast, and take their course and degrees there. *e.* Those who take the licence of the Apothecaries' Hall. *f.* Those who pursue their studies in Ireland, but who migrate to London, Edinburgh, or Glasgow for their licences.

We do not attempt to give details as to the requisite courses of instruction for degrees or diplomas, as our epitome must necessarily be insufficient for the information of the student, and we can occupy our available space with information more useful to him. The official information upon which students may depend can be obtained by sending a note to the Registrars of the Licensing Bodies or Schools.

THE UNIVERSITY OF DUBLIN.

The University of Dublin grants the degrees of M.B., B.Ch., and B.A.O. to students who have obtained their B.A. degree, and who have been for at least five academic years on the books of the Medical School, and the higher degrees of M.D., M.Ch., and M.A.O. to graduates of certain standing who hold the degrees of M.B., and B.Ch. It does not grant degrees to any but graduates in Arts, and consequently its degrees hold a high rank, and are sought for by those who look forward to occupying the best positions in the profession.

The expense of obtaining the degrees of M.B., B.Ch., and B.A.O. is approximately as follows:—Lectures, £67 4s. 0d.; Hospitals, £55 13s.; Degree Fees, £27.—Total, £149 17s. 0d.

The expense of the B.A. degree, amounting altogether to £83 4s., should be added, making the total cost £233 1s. 0d.

Diploma in Medicine, Surgery, and Midwifery.—Candidates for the diplomas in Medicine, Surgery, or Obstetric Science must be matriculated in Medicine, and must have completed two years in Arts and five years in medical studies. The medical course and examinations are the same as for the degrees. Fees for the diplomas in medicine, surgery, and midwifery, £21. A diplomate, on completing his course in Arts and proceeding to the degree of B.A., may become a Bachelor of Medicine on paying the degree fees.

In addition to its ordinary qualifications the University grants the following degrees and diplomas:—

Doctor of Medicine.—To obtain this the candidate must have passed the final examinations, and be of M.A. standing. He must then read a thesis before the Regius Professor of Medicine. Fee for this degree, £13.

Master of Surgery.—The candidate must be a Bachelor in Surgery of three years' standing, and must then pass an examination in clinical surgery, operative surgery, surgical pathology, surgery, and surgical anatomy (on the dead subject). Fee for this degree, £11.

Master in Obstetric Science.—The candidate must have passed the M.B. and B.Ch. examinations, and have completed, in addition to the courses for M.B., B.Ch., a course of obstetric medicine and surgery. He is then required to pass an examination in the following subjects:—Practice of midwifery, gynæcology, anatomy of female pelvis and elementary embryology, and clinical gynæcology. Fee for this degree, £5.

Diploma in Public Health.—The candidate must be a Registered Medical Practitioner; must have completed, subsequent to obtaining a registrable qualification, four months' practical instruction in a laboratory in practical work in chemistry and bacteriology applied to public health; he must have studied practically outdoor sanitary work for six months under an approved officer of health; and have attended, after qualification, for three months, the practice of a hospital for infectious diseases.

Degrees in Dental Science.—Candidates for the B.Dent.Sci. degree in dental science must have taken a degree in Arts, and must have had their names in the books of the Medical School for four years. Three examinations must be passed—namely, the Preliminary Scientific at the end of the first year, the Intermediate at the end of the third year, and the Final Dental at the end of the fourth year. The total fees are £280 2s.

QUEEN'S UNIVERSITY, BELFAST.

The Queen's University confers the degrees of M.B., B.Ch., and B.A.O., on students who have followed the prescribed course of studies for five academical years, and passed the prescribed examinations. At least three of the years are spent in attendance on courses at the University. The expense is about £105.

Degrees of M.D., M.Ch., and M.A.O.—These degrees are not conferred until the expiration of at least three academic years, or, in the case of graduates of the University in Arts or Science, of at least two academic years, after admission to the primary degrees in the Faculty of Medicine. Every candidate must show that in the interval he has pursued such courses of study, or been engaged in such practical work as may be prescribed. These degrees may be conferred by the Senate either (*a*) after an examination, which includes written, oral, clinical, and practical examinations; or (*b*) on the submission of a thesis or other evidence of original study or research, to be approved by the Faculty of Medicine, after an oral or other examination of the candidate on the subject thereof. On application for these degrees a fee of £2 2s., and on admission to them a fee of £8 8s., must be paid.

The subjects of the examination for the degree of M.D. are:—The Principles and Practice of Medicine, and one other special subject to be selected by the candidate from: (i.) Human Anatomy, including Embryology; (ii.) Physiology; (iii.) Pathology; (iv.) Pharmacology and Therapeutics; (v.) Sanitary Science and Public Health; (vi.) Forensic Medicine and Toxicology; (vii.) Mental Diseases.

The subjects of the examination for the degree of M.Ch. are:—(1) Surgery, Theoretical and Practical, including Ophthalmology and Otology. (2) Surgical Pathology. (3) Surgical Anatomy and Operative Surgery, with the use of surgical instruments and appliances.

The subjects of the examination for the degree of M.A.O. are:—(1) Midwifery. (2) Diseases of Women and Children. (3) Pathology in its special bearing on Midwifery, and Diseases of Women and Children.

Diploma in Public Health.—This diploma is given after examination to registered medical men, on similar conditions to those obtaining elsewhere.

NATIONAL UNIVERSITY OF IRELAND.

The National University of Ireland confers the degrees of M.B., B.Ch., and B.A.O., on students who have followed the prescribed course for five academic years, and passed the prescribed examinations. At least three years must be spent at one of the constituent colleges of the University, viz., the University Colleges at Dublin, Cork, and Galway. The University also confers the higher degrees of M.D., M.Ch., M.A.O., B.Sc. (Public Health), D.Sc. (Public Health), B.D.S., and M.D.S.

The expense of obtaining the degrees of M.B., B.Ch., and B.A.O., is approximately:—Lectures, £68 5s.; Hospitals, £56 14s.; University Fees, £19. Total, £143 19s.

The conditions for the higher degrees are:—

Doctor in Medicine.—Candidates may present themselves for the examination for this degree after an interval of three academical years from the time of obtaining the M.B., B.Ch., B.A.O. degrees; but in the case of candidates who have obtained a degree of the University in the Faculty of Arts, an interval of two academical years is sufficient.

Candidates must at the same time produce a certificate of having been, for at least two academical years, engaged in hospital or private medical, surgical, or obstetrical practice respectively, or in the military or naval medical service.

Candidates at this examination must answer in Medicine and Pathology.

The examination in each subject consists of:—

(*a.*) A Written Examination.
(*b.*) An Oral Examination.

In addition every candidate must diagnose at the bedside at least three medical cases, and prescribe treatment. He must also write detailed reports on at least two cases, to be selected by the examiners, and discuss the questions arising thereon. Fee, £10.

Master in Surgery.—The following are the subjects of examination:—

Surgery, theoretical and practical, including Ophthalmology and Otology; Surgical Pathology; Surgical Anatomy and Operative Surgery, with the use of Surgical Instruments and Appliances.

The other conditions are the same as for the M.D. degree. Fee, £10.

Master in Obstetrics.—Academic standing is as for the two previous degrees.

Each candidate must furnish satisfactory evidence that since graduating in medicine he has (1) had personal charge of at least *twenty* cases of labour; and (2) attended during a period of three months the practice of a clinical hospital for diseases of women, where at least six beds are in constant occupation, or in a special ward of a general hospital, where such cases only are treated, and containing at least six beds in constant occupation.

Candidates at this Examination must answer in the following subjects:—Midwifery, Diseases of Women and Children, Pathology, the Use of Instruments and Appliances. The Examination in each subject consists of—(*a*) an Oral Examination, with practical illustrations, including use of instruments and appliances; (*b*) a written Examination; (*c*) a clinical Examination, as far as practicable. Fee, £10.

Bachelor of Science, Public Health.—A candidate shall not be admitted to receive the Degree of Bachelor of Science, Public Health, unless he—(*a*) shall have received the Degrees of M.B., B.Ch., and B.A.O. at least one year previously; (*b*) shall have pursued an approved course of study in the Faculty of Medicine; and (*c*) shall have passed the prescribed examination. Fee, £7.

Courses.—In addition to D.P.H. Course:—(1) Special Pathology (three months). (2) Bacteriology, second course (three months). (3) Advanced Course in Hygiene (three months).

Doctor of Science, Public Health.—The regulations are not yet published. Fee, £10.

Diploma in Public Health.—This Diploma may be granted to matriculated students of the University who shall have completed courses of study, approved for the purpose, and shall have passed the prescribed examinations: provided that it shall not be granted except to a registered medical practitioner.

The conditions and examination are similar to those already quoted for the University of Dublin.

Degrees in Dentistry.—Candidates for the Degree of B.D.S. shall be required to pass, after matriculation, four University Examinations, namely:—A First University Examination in Medicine, as for medical students; a Second University Examination in Medicine, as for medical students; an Intermediate University Examination in Dental Surgery; a Final Examination for the Degree of B.D.S.

Students must follow a definite course of instruction, and must be, for at least two years, apprenticed to a registered dentist.

The regulations for the degree of M.D.S. are not yet published.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.

Examinations are held conjointly by the two Colleges. The course, as in other bodies, extends over five years, with examinations at the end of the first, second, third, and final years. These examinations are conducted by examiners chosen by each of the Colleges for the subjects appropriate to them. The curriculum has recently been revised, and made of a more practical nature. As in the English Colleges, the subjects of the First Professional Examination may be studied either at a medical school or at an institution other than a medical school which is recognised by the Colleges, after due inspection, for instruction in these subjects. We recommend students to apply for the official programme to the Secretary of the Committee of Management, Royal College of Surgeons, or to the Registrar of either College. In the case of the Preliminary Examination seven clear days' notice must be given to the Secretary; fourteen days' notice is required from candidates for the Professional Examinations.

The total of the examination fees, spread over the four examinations, is £42, while the school and hospital fees, if taken in Dublin, amount to £124 19s., making altogether £166 19s., exclusive of re-examination fees, which have to be paid in case the candidate fails to pass his examination.

The Colleges also confer a Diploma in Public Health, of which information will be found on page lvi

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

This College issues a Licence in Medicine and a Licence in Midwifery to registered medical practitioners.

Licence in Medicine.—The subjects of examination are:—Practice of Medicine, Clinical Medicine, Pathology, Medical Jurisprudence, Midwifery, Hygiene and Therapeutics.

Licence in Midwifery.—The subjects of examination are:—Gynæcology and Midwifery. A Registered Medical Practitioner of five years' standing is exempted from the examination by printed questions.

Fees.—Fee for the Licence to Practise Medicine, £15 15s. Fee for the Licence to Practise Midwifery, £5 5s.

Membership.—The Membership is open to University Graduates in Medicine and to Licentiates of the Royal Colleges of Physicians of the United Kingdom. The Examinations for Membership are held in January, April, July, and October, and such other times as the President may appoint. Fee to Licentiates of the College, £21, to others £36 15s.

Fellowship.—Fellows are elected from among the members of at least one year's standing. Fee £60.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

This College grants a Licence in Surgery to registered medical practitioners.

The subjects, methods, times, and places of examination are those of the surgical group of the Final Professional Examination of the Conjoint Board in Ireland of the Royal College of Physicians and the Royal College of Surgeons. (See their regulations.) Candidates must pass in all the subjects at one examination. Special examinations will not be granted under any circumstances.

A candidate whose name is entered either on the Medical Register for the United Kingdom, the Colonial Medical Register, or the Foreign Medical Register of the year in which he presents himself for examination, and who satisfies the Council that he has passed through a course of study and examinations equivalent to those required by the regulations of the Conjoint Board of the Royal College of Physicians of Ireland and the Royal College of Surgeons in Ireland, preceded by the passing of an examination in Arts recognised by the General Medical Council, may, at the discretion of the Council, be admitted to the examination.

Candidates are required to lodge their applications, declarations, and certificates with the Registrar, at least twenty-one days before the date of the examination.

The fee for examination is for each admission five guineas. Of these fees five guineas will be reckoned as part of the fee payable upon admission to the Licence in Surgery. The fee to be paid upon admission to the Licence in Surgery is twenty-five guineas.

Fees will not be returned under any circumstances.

All applications with reference to the examination for the Licence in Surgery should be addressed to the Registrar, Royal College of Surgeons in Ireland, Dublin.

Fellowship.—The examination for the Fellowship is divided into two parts,—viz.: The Primary and the Final. The subjects of the primary examination are—anatomy, including dissections, physiology, and histology. The examination is partly written, partly *viva voce*, and partly practical. Candidates must pass in all the subjects at one examination. The subjects of the final examination are—Surgery, including surgical anatomy, and pathology. The examination is partly written, and partly *viva voce*, and includes the examination of patients, and the performance of operations on the dead body. Candidates must pass in all the subjects at one examination. The examinations are held three times in each year, commencing :—The primary on the first Monday in March, the third Monday in July, and the third Monday in November. The final on the second Monday in March, the third Wednesday in July, and the fourth Monday in November. Special examinations will not be granted under any circumstances. Candidates are required to lodge their applications, certificates, and receipts for fees with the Registrar, at least seven days before the date of the examination.

Fees.—1. The fees for examinations are as follows :—Primary examination, each admission, 5 guineas ; final examination, each admission, 5 guineas. 2. Of these examination fees ten guineas will be reckoned as part of the fee payable upon admission to the Fellowship. 3. The fee to be paid upon admission to the Fellowship is forty guineas, except when the candidate is a Licentiate of the College, in which case the fee is twenty-five guineas.

All applications with reference to the examinations for the Diploma of Fellow should be addressed to The Registrar, Royal College of Surgeons in Ireland, Dublin.

Licence in Dental Surgery.—Candidates for the licence in Dental Surgery are required to pass two professional examinations. They must have passed a recognised Preliminary Examination in general education, and been registered as medical or dental students by the General Medical Council. They must have been engaged during a period of two years in acquiring a practical familiarity with the details of mechanical dentistry under the instruction of a registered dentist, or under the direction of the superintendent of the mechanical department of a recognised dental hospital where the arrangements for teaching mechanical dentistry are satisfactory to the Council of the College. This instruction may be commenced or attended before the candidates register as medical or dental students. They must have been engaged during four years in the acquirement of professional knowledge subsequently to the date of registration as a medical or dental student. One year's *bona fide* apprenticeship with a registered dental practitioner, after being registered as a medical or dental student, may be counted as one of the four years of professional study. Candidates must produce evidence of having followed a prescribed course of study. There are special exemptions in the case of persons already holding a surgical or dental qualification. All applications with reference to the examination for the Diploma in Dental Surgery should be addressed to The Registrar, Royal College of Surgeons in Ireland, Dublin.

APOTHECARIES' HALL OF IRELAND.

The Licence of this Hall is granted to students who present certificates of having completed the course of study as laid down in the curriculum, and who pass the necessary examinations. The diploma of the Apothecaries' Hall of Ireland entitles the holder to be registered as a practitioner in medicine, surgery, and midwifery, and possess the privileges of an apothecary.

There are three professional examinations, the total fees for which amount to thirty guineas. Women are eligible for the diploma.

Registered medical practitioners receive the diploma of the Hall upon passing an examination in the subject or subjects not covered by their previous qualification, and on paying a fee of fifteen guineas.

The fees payable for each examination are as follows : Professional Primary, £5 5s. ; Intermediate, £10 10s. ; Final Examination, £15 15s.

Applications and schedules, together with bank receipt for the fee, must be lodged with the Registrar, Apothecaries' Hall, 40 Mary Street, Dublin, at least fourteen clear days before the day of examination.

Each candidate before receiving his diploma must produce evidence that he has attained the age of 21.

Each candidate must produce evidence of having before entering on medical studies passed a preliminary examination in general education.

The details of the course of education required and syllabus of the examinations will be supplied on application to the Registrar at 40, Mary Street, Dublin.

THE DIPLOMA IN PUBLIC HEALTH.

This diploma is granted by Dublin University, the National University, Queen's University, and the Conjoint Royal Colleges. Every candidate must be a registered medical practitioner. The examination is in :—(1) Chemistry (including chemical physics). (2) Engineering and architecture. (3) Sanitary law and vital statistics. (4) Hygiene. (5) Bacteriology. (6) Meteorology. The General Medical Council recommend that all candidates shall have studied in a special bacteriological laboratory, also for six months as pupil of a working medical officer of health, described, for Ireland, as " the medical officer of health of a county or of one or more sanitary districts having a population of not less than 30,000 ; or a medical officer of health who is a teacher in Public Health of a recognised medical school."

THE IRISH MEDICAL SCHOOLS.

The Irish Medical Schools are as follows :—

The School of Physic of Dublin University.—Every student of the school must be matriculated in Medicine, for which a fee of 5s. is payable, but he need not attend any of the Arts courses unless he desires to obtain a University licence or degree in medicine, surgery, and midwifery. No student is permitted to matriculate unless he has passed the Entrance Examination of Trinity College, or some other examination recognised by the General Medical Council. Two medical scholarships are given annually at the School of Physic, value £20 per annum, tenable for two years, the examinations for which are held each year in June ; one scholarship is given in anatomy and institutes of medicine ; the other in zoology, chemistry, botany, and experimental physics. A prize of £100 is awarded by the Board to the successful candidate at a special examination in alternate years in medicine or in surgery, provided that the merit be deemed sufficient. The successful candidate is required to spend three months in the study of medicine or surgery, as the case may be, in Berlin, Paris, or Vienna. Before he can obtain the first instalment of £50 he must satisfy the Senior Lecturer that he possesses sufficient knowledge of a Continental language to derive full benefit from the prize. The examination is held in June, and is open to students who have passed the Final Examination in Medicine or in Surgery, as the case may be, within two years of the examination.

In order to obtain the second sum of £50 the prizeman must have furnished to the Regius Professor his formal report on the hospitals attended by him within two years from the time of obtaining the prize.

The Sir John Banks Medal and Prize, founded by the late Sir J. Banks, M.D., formerly Regius Professor of Physic, are awarded to the best and second best answerers at the Medical Travelling Prize Examination.

The Edward Hallaran Bennett Medal and Prize, founded by pupils of the late Dr. E. H. Bennett, formerly Professor of Surgery, are awarded to the best and second best answerers at the Surgical Traveling Prize Examination.

Class prizes are given at the end of the session of between £5 and £10 in value. The John Mallet Purser Medal, founded by Prof. Purser's past pupils, is awarded annually to the student who, at the ordinary June Intermediate Medical Examination, Part I., in Anatomy and Institutes of Medicine, obtains highest marks in Physiology and Histology, provided that he passes the examination in full, and the Cunningham Medal, *in memoriam* of the late Prof. D. J. Cunningham to the student, who, at the same examination, obtains highest marks in Anatomy, and passes the examination.

Fitz-Patrick Scholarship.—This scholarship consists of the interest on £1,000. It is awarded annually to the student who obtains the highest aggregate marks at the five sections of the Final Examinations, provided that he has completed his medical course in the prescribed period of five years.

A School of Dental Science has been organised in connection with the School of Physic in Trinity College. Lectures are given in anatomy, chemistry, surgery physics, physiology and histology, dental mechanics, orthodontia and anæsthetics.

Post-Graduate Classes.—A short post-graduate course is now given annually in September in connection with Trinity College Medical School. It includes special work on Diseases of the Eye, Nose, and Throat, Gynæcology, Diseases of the Skin, X-ray work, Medicine, Surgery (clinical and operative), and Clinical Pathology.

The Royal College of Surgeons in Ireland. Schools of Surgery.—These schools are attached by Charter to the Royal College of Surgeons, and have existed as a department of the College for over a century. They are carried on within the College buildings, and are subject to the supervision and control of the Council. The buildings have been reconstructed, the capacity of the dissecting room nearly trebled, and special pathological, bacteriological, public health, chemical, and pharmaceutical laboratories fitted with approved appliances, in order that students may have the advantage of modern methods of instruction. There are special rooms set apart for women students.

All the lectures and courses of practical instruction may be attended by medical students who are otherwise unconnected with the College.

All the diplomas of the College are open to students of either sex. Separate rooms have been provided, and careful provision made for the instruction and comfort of women students.

Prizes.—The Barker Prize, £26 5s.; the Carmichael Scholarship, £15; the Mayne Scholarship, £8. The Gold and Silver Medals in Surgery and the Stoney Memorial Gold Medal in Anatomy.

Class Prizes of £2 and £1, accompanied by silver medals if sufficient merit is shown, will also be given in each subject. Prospectus and Student's Guide can be obtained on application to the Registrar, Royal College of Surgeons, Dublin.

University College, Dublin.—This College is a constituent college of the National University of Ireland, for whose examinations and degrees it trains students. The examinations are conducted by the professors in the College, in conjunction with extern examiners appointed by the University.

Medical students must be registered with the Branch Medical Council at the commencement of their period of study. Forms of application can be obtained and filled up in the College. Information in respect of the necessary conditions for registration may be obtained from the Registrar of the College at the Medical School. The student must bring with him the certificate of his Matriculation examination, or of the Senior Grade examination of the Intermediate Education Board in the necessary subjects, and his birth certificate. Non-matriculated students intending to study medicine must have passed a Preliminary Examination, accepted by the General Medical Council, in English, Latin, Mathematics, and a Modern Language or Greek. Intending medical students who, for any reason, cannot begin the study of Medicine in the Winter Session, may do so in the Summer Session, but will not be able to complete the lectures of the first medical year until the following Winter Session.

The Scholarship Regulations provide for Six Scholarships of £30 each, tenable for one year in each of the 2nd, 3rd, 4th and 5th years of study. The Examinations for the Scholarships are held in October, the subjects being those studied in the previous year which Candidates must have attended in the College. Scholarships tenable for one year are offered at entrance at an Examination common to all Faculties.

There are Exhibitions of the value of £20 and £10 offered to students of the College at each of the Medical Examinations of the University; and a Gold Medal to the most distinguished answerer at the M.B., B.Ch., and B.A.O. Examination of the year.

Courses of lectures in Dental Surgery and Dental Mechanics are given to Dental students.

The Queen's University of Belfast.—This University provides all the classes required for a complete medical curriculum. The University contains laboratories in connection with the departments of Biology, Chemistry, Physiology, Pathology, Anatomy, Physics, and Materia Medica. In connection, too, is a Students' Union, which gives students the advantage of dining-rooms, reading-rooms, a library, and various recreation rooms. Women are eligible as students. Clinical instruction is given at the Royal Victoria Hospital, which was rebuilt a few years ago, and has 300 beds, and at the Mater Infirmorum Hospital, which has 160 beds. Other hospitals open to the students of the University are: The Maternity Hospital, the Ulster Hospital for Women and Children, the Hospital for Sick Children, the Ophthalmic Hospital, the Benn Ulster Eye, Ear, and Throat Hospital, the Union Infirmary and Fever Hospital, the Fever Hospital, Purdysburn, and the District Lunatic Asylum.

Scholarships.—(1) Twelve Entrance Scholarships, value £40, open to students of Art, Science and Medicine; (2) two Dunville Studentships (one each alternate year), value £150 each; (3) one Andrews Studentship each alternate year, value £145; (4) numerous sessional prizes.

Sixteen scholarships, value £15-£40, are now open for competition at the medical examinations in March and June. There is also a Post-Graduate Research Fund open to all graduates of not more than three years' standing. Information regarding these scholarships, etc., may be obtained on application to the Secretary of the University.

Fees.—The cost of the curriculum intended for students proceeding to the degrees of the Queen's University of Belfast is, approximately, £105. This includes examination fees and a perpetual ticket for attendance at the Royal Victoria Hospital or the Mater Infirmorum Hospital, but not fees for the special hospitals.

A pamphlet containing full information regarding the new regulations for courses, fees, etc., can be had free of cost on application to the Secretary, Queen's University, Belfast.

The University Colleges—Cork and Galway.—These important academic institutions educate students for all degrees and licenses, and are maintained, as hitherto, by Government grants. Various exhibitions and scholarships are available. Each college has the disposal of about £1,500 per annum in scholarships and prizes. The colleges are equipped with students' reading rooms and lending libraries and refreshment rooms, and with all adjuncts to collegiate life, such as literary societies and athletic organisations. The expense of living in the collegiate towns is quite moderate. The scholarship examinations are held in October.

These Colleges are now constituent colleges of the National University of Ireland, and conduct examinations admitting to its degrees.

University College, Cork.—The arrangements in the Faculty of Medicine are made chiefly with reference to the requirements of the National University of Ireland, but students proceeding for the examinations of the Conjoint Boards of England, Scotland, or Ireland, can arrange the course of lectures which they attend, and the order in which they attend them, to meet the requirements of those bodies. Certificates of attendance in the college are also accepted by the University of London. The total fees for the college lectures and hospital attendances required by the National University of Ireland are about £104.

Clinical instruction is given at the North and South Infirmaries and at the Cork Union Hospital. Students can also attend the Mercy Hospital, the County and City of Cork Lying-in Hospital, the Maternity Hospital, the Hospital for Diseases of Women and Children, the Fever Hospital, the Ophthalmic and Aural Hospital, and the Eglinton Lunatic Asylum. The winter session commences on October 1st, and ends at the end of April. The courses of the summer session are delivered in the months of April, May, and June.

Between forty and fifty scholarships open to Medical Students are awarded annually (values £20-£50), as well as the Blayney Scholarship. This Scholarship, worth about £32, will be awarded to the candidate obtaining the highest marks in Honours at the M.B., B.Ch., B.A.O. Examination, held in Autumn at the College.

Further information can be obtained in the College Regulations, or on application to the Registrar, University College, Cork.

University College, Galway.—Clinical teaching is carried on in the Galway Hospital, established as a Public General Hospital (in the place of the County Galway Infirmary) by Act of Parliament 1892. The Galway Fever Hospital and Galway Union Hospital are also open to students. The conditions of residence required by the National University for graduation may be observed in Galway. The lectures qualify for the other licensing bodies.

Prizes.—There are eight Junior Scholarships in Medicine of the annual value of £25 each. Two are tenable by matriculated students of the first, second, third, and fourth years respectively. There are, besides, private Foundation Scholarships open to medical students and tenable with medical scholarships. Sessional prizes are offered in each subject.

Like the sister college of Cork, this college is now a constituent college of the National University of Ireland.

ROYAL COLLEGE OF SCIENCE FOR IRELAND.

This College, situate in St. Stephen's Green, Dublin, supplies a complete course of instruction in science applicable to the industrial arts, especially those which may be cast broadly under the heads of Agriculture, Chemical Manufactures, Engineering, Physics, and Natural Science. A Diploma of Associate of the College is granted at the end of the three years' course. Non-associate students may join for any course required. There are several entrance scholarships, (*a*) in Agriculture, and (*b*) in Science and Technology, tenable for three years, of the value of £50 each yearly, with free tuition. There are four Royal scholarships of the value of £50 each yearly, with free education, tenable for two years. Two are competed for by the first year associate students at the end of each session. All the laboratories and drawing schools are open daily for practical instruction. The Science Scholarship Examinations are held during the first week in July, the Examinations for Agricultural Scholarships in the first week in September, and the Entrance Examination for intending Associates in the third week of September. For further particulars and copy of college programme apply to the Registrar.

THE DUBLIN HOSPITALS.

The clinical hospitals in Dublin are ten in number, exclusive of three lying-in hospitals. There are also two children's hospitals, an orthopædic hospital, a fever hospital, an ophthalmic hospital, a dental hospital, and other special institutions. Some of the clinical hospitals, though they have no actual or official connection with any school, are in close affinity with certain teaching bodies; while others, again, are without any special connection with any school. While, however, such association of school and hospital may exist, it should be remembered that the Dublin schools and hospitals are open to all comers, and the student is free to attend any hospital or any school he wishes, and to change his hospital from year to year as he may see fit.

The Irish licensing bodies require attendance on hospitals for twenty-seven months—*i.e.*, three winter sessions of six months and three summers of three months, within the five years of study. The fee at all general hospitals is £8 8s. in winter, and for the summer £5 5s., or £12 12s. for the entire session of nine months if taken together. All the Dublin hospitals receive students as residents.

GENERAL HOSPITALS.

Richmond, Whitworth, and Hardwicke Hospitals.—These hospitals contain over 300 beds. They are visited each morning at nine o'clock by the physicians and surgeons, and, in addition to the usual bedside instruction, clinical lectures are delivered on the most important cases. Instruction is also given on various special branches of medicine and surgery. The Truss Establishment, for the distribution of trusses to the ruptured poor of Ireland, is connected with these hospitals. There are ophthalmic, aural, throat, and gynæcological dispensaries, and instruction in these important subjects is given. A modern pathological laboratory, and a new mortuary have been opened recently. Twelve resident clinical clerks are appointed each quarter, and provided with furnished apartments, fuel, &c. The appointments are open not only to advanced students, but also to those who are qualified in medicine and surgery. A house surgeon for the Richmond Hospital and a house physician for the Whitworth and Hardwicke Hospitals are elected every six months, and receive a salary. The Richmond Lunatic Asylum, containing 1,200 beds, adjoins the hospital.

Meath Hospital and Co. Dublin Infirmary.—This hospital was founded in 1753, and now contains 160 beds available for clinical teaching. A new building for the isolated treatment of fevers, containing 40 beds, has recently been added. The certificates are recognised by all the universities and licensing bodies of the United Kingdom. Medical and surgical resident pupils and clinical clerks and dressers are appointed every three months, and two house surgeons are elected annually. A prospectus giving the complete arrangements for medical and surgical classes for the coming session may be obtained from the Secretary of the Medical Board, Mr. Henry Stokes, F.R.C.S.I., 32, Upper Pembroke Street.

The Adelaide Medical and Surgical Hospitals occupy a central position within a few minutes' walk of the College of Surgeons and Trinity College. From October 1st, the physicians and surgeons visit the wards and give instruction at the bedside at the advertised hours. There is a large detached fever hospital, and there are wards for infants and children. Operations are performed, at 10 a.m. on Tuesday, Thursday, and Friday. Special hours are devoted to clinical instruction in the diseases peculiar to women; also special instruction is given on practical pathology and X-ray photography. Two House Surgeons are elected annually and four resident pupils half-yearly. Prize examinations for the Hudson Scholarship of £30 and a gold medal, and Hudson prize of £10 and a silver medal, and for surgical, medical and dermatological prizes, are held at the termination of the session. The large dispensaries afford facilities for the study of ear, throat, and cutaneous diseases, as well as of minor surgery and dentistry. Further particulars from Dr. H. T. Bewley, 89 Merrion Square.

The Royal City of Dublin Hospital.—This hospital has recently been enlarged and improved. A special course of instruction is given in ophthalmic and aural diseases. There are special wards for the treatment of diseases of the eye, of children, and of women, and practical instruction is given on diseases peculiar to women; there is also a separate building for infectious diseases. Clinical clerks to the physicians and dressers to the surgeons are appointed from the most deserving of the class. A new operation theatre, sterilising room, and anæsthetic room have been constructed in accordance with modern surgical requirements. A department for Röntgen-ray and light treatment of lupus has been added. A resident medical officer is elected annually, and resident medical and surgical pupils are appointed from among the past and present students of the hospital. Operations are performed on Tuesdays, Thursdays, and Saturdays, at 10 a.m. Special classes for first year students. Full particulars can be had on application to Hon. Sec. Med. Board.

Sir Patrick Dun's Hospital is situated on the south-eastern side of the city, and about a quarter of a mile from the University School of Physic. It is officered almost exclusively by the professors in that school. Formerly all University students were compelled to attend this hospital, which was purely a medical institution, but many years ago the obligation was removed, and the hospital was opened for surgical cases. It is now open to all students. There is a special wing devoted to fever cases, and regular clinical instruction is given by the members of the medical staff throughout the winter and summer sessions. Special classes for students commencing their hospital studies will be held in the wards during the months of October, November, and December. They will embrace the elements of medicine and surgery, including note-taking. Opportunities are also afforded to students for examining cases of throat, ear, and eye diseases, as well as for performing minor surgical operations and bandaging. In the X-ray Department opportunities are given the members of the hospital class of seeing the various applications of the X-rays to the diagnosis and treatment of injury and disease. Arrangements have been made for practical instruction in anæsthetics. A department for dentistry has lately been added.

*Mater Misericordiæ Hospital, Dublin.—This hospital, at present containing 345 beds, is open at all hours for the reception of accidents and urgent cases. Clinical instruction is given by the physicians and surgeons at 9 a.m. daily. A course of clinical instruction on fever is given during the winter and summer sessions. A certificate of attendance upon this course, to meet the requirements of the licensing bodies, may be obtained. Ophthalmic surgery is taught in the special wards and in the dispensary. Surgical operations are performed on Mondays, Tuesdays, Fridays and Saturdays at 11 o'clock. Connected with the hospital are extensive dispensaries, which afford valuable oportunities for the study of general medical and surgical diseases and accidents. Instruction is given in pathology and bacteriology. Three house physicians, six house surgeons, and 16 resident pupils are elected annually. Dressers and clinical clerks are also appointed, and certificates are given to those who perform their duties to the satisfaction of the staff. Leonard Prizes are offered for competition annually. For further particulars see prospectus. Certificates of attendance upon this hospital are recognised by all the universities and licensing bodies in the United Kingdom. A training school and a home for trained nurses have been opened in connection with the Hospital.

Terms of attendance.—Nine months, £12 12s.; six winter months, £8 8s.; three summer months, £5 5s. Entries can be made with any of the physicians or surgeons, or with the Registrar, Dr. Martin Dempsey, 35 Merrion Square. A prospectus containing in detail the arrangements for clinical instruction, prizes, etc., may be obtained from the Secretary, Medical Board.

Mercer's Hospital.—This hospital, founded in 1734, is situated in the centre of Dublin, in the immediate vicinity of the Schools of Surgery of the Royal College of Surgeons, the National University School of Medicine, and Trinity College. It contains 120 beds for medical and surgical cases, and arrangements have been made with the medical officers of Cork Street Fever Hospital whereby all students of this hospital are entitled to attend the clinical instruction of that institution. There is a large out-patient department, and a special department for diseases peculiar to women. There are also special wards for the treatment and study of children's diseases. During the past few years the hospital has undergone extensive alterations in order to bring it up to modern requirements. A house surgeon is appointed annually. Five resident pupils are appointed, each for six months, and clinical clerks and dressers are appointed monthly from among the most deserving members of the class. The certificates of this hospital are recognised by all the licensing bodies. For further particulars apply to Mr. Seton Pringle, F.R.C.S., 7, Fitzwilliam Place, Dublin.

St. Vincent's Hospital was established in 1834. It has 160 beds, and in connection with it there is a largely attended dispensary, and a nurses' institute. In addition to the ordinary clinical instruction, systematic courses of lectures are given in each department of medicine and surgery, and are illustrated by cases in the hospital. The resident officers consist of two house surgeons, two house physicians, and six resident pupils. Three clinical lectures are delivered daily in the wards, illustrated by selected cases, and beginning at 9 a.m. Two gold medals and other valuable prizes and certificates of merit are awarded at the end of each session. A prospectus can be had from Mr. Kennedy, 68 Merrion Square.

*Dr. Steevens' Hospital, situated at Kingsbridge, is one of the oldest and largest clinical hospitals in Dublin, and contains over 200 beds. A new dispensary and out-patient department has been completed and opened to patients. There is accommodation for twelve resident pupils—four medical, six surgical, and two in the special departments, each of whom is supplied with a separate room. All information with regard to these appointments can be had from the Resident Medical Officer at the hospital. Licensing bodies recognise six months' residence as equivalent to a year's ordinary attendance at hospital. The manufactories and railway works in the neighbourhood supply this hospital with large numbers of accidents and other cases, while a special ward for venereal disease affords exceptional opportunities for the study of this important subject.

Jervis Street Hospital is the oldest established in Dublin. The present building was completed in 1896, since which time it has been open for the reception of patients. In addition to large medical and surgical dispensaries, the new out-patient department which is now completed, includes special, departments for the treatment of diseases of the skin, eye, ear, and throat, and diseases peculiar to women. Six resident surgeons are appointed annually. Clinical clerks and surgical dressers are selected from among the most attentive of the advanced students without the payment of any additional fee. Twelve resident students are appointed annually. Special certificates are given to resident pupils and dressers who have performed their respective duties to the satisfaction of the physicians and surgeons.

Students of Jervis Street Hospital are entitled to attend free of charge special courses in fevers at Cork Street Fever Hospital. Prospectus and all particulars may be obtained from the Hon. Secretary of the Medical Board, Dr. F. X. Callaghan, 25 Westland Row, Dublin.

SPECIAL HOSPITALS.

The chief of the special hospitals of Dublin are the Rotunda, the Coombe, and the National Lying-in-Hospitals, Cork Street Fever Hospital, the Royal Victoria Eye and Ear Hospital (amalgamation of St. Mark's Ophthalmic Hospital and the National Eye and Ear Hospital), the Dental Hospital, the Orthopædic Hospital, and the Children's Hospitals in Harcourt Street and in Temple Street.

The Rotunda Hospital.—This institution is the largest and the oldest gynæcological and maternity hospital in the British Empire. The work performed by it is about three times greater than that of any other hospital of its kind in Ireland. The number of patients admitted to the hospital, and of those attended in the extern maternity has increased enormously within recent years. The routine daily work comprises the attendance on lectures on midwifery and gynæcology; practice in abdominal palpation; personal conduction of parturition both in the extern and the intern maternities; cystoscopic examinations; and attendance at the operative work of the hospital, in which the students assist. The hospital affords exceptional advantages to qualified men and women, for they (if considered competent) are permitted a certain amount of practical operative work—viz., use of forceps, curettings, perinœorrhaphy, etc. A special afternoon class in gynæcology is held by the Senior Assistant, and one in special pathology by the Pathologist. Fee for each, £2 2s. per month. The pathological laboratory has become an important feature of the hospital. Students can enter at any time for periods of one month or longer. Certificates of attendance are accepted by all the licensing bodies. The L.M. certificate is obtained by attendance at the hospital for six months, with the subsequent passing of an examination. A special certificate in gynæcology is presented to students whose work meets with the Master's approval. Paid clinical assistants are selected (from amongst those who have obtained the hospital L.M. certificate), for periods of six months. Women students can also reside in the hospital under conditions similar to men. The grounds of the hospital contain grass courts for lawn tennis and croquet, and a skating rink. The entire students' quarters have been rebuilt and refurnished, with electric light, new bath-rooms, reading-room, new billiard table, etc.

Fees for Pupils.—Intern :—One month, £6 6s. two months, £9 9s.; three months, £12 12s.; six months, £21; single months other than the first, £4 4s.; board and lodging in the house per week, £1 5s. Night students (not resident in house), £6 6s. for first three months; £4 4s. for the second three months. For further particulars apply to the Master, Dr. Henry Jellett, Rotunda Hospital, Dublin.

Coombe Lying-in Hospital.—This hospital, which devotes itself to the care of lying-in women, and to the treatment of diseases peculiar to women, was founded in 1826. The original hospital was removed, and the present maternity hospital erected in 1875. An up-to-date labour theatre and waiting ward were added in 1904. The new Gynæcological Hospital was finished in 1903. It contains two modern operating theatres. The former Gynæcological Hospital has been converted into sleeping rooms for resident pupils. The Pembroke Dispensary was opened in 1911. The hospital is situated centrally in a most densely populated district. In addition to a very large gynæcological practice, over 2,000 women are delivered annually. The Master visits the maternity wards daily with the students at 9.30 a.m. This is followed by a lecture on midwifery. At 11 a.m. the gynæcological wards are visited; following this a lecture on gynæcology, physical examinations, and operations take place in the theatres. At 4 p.m. on Mondays, Wednesdays, and Fridays, the Master conducts the gynæcological out-patient dispensary. This dispensary affords students exceptional advantages of acquiring a thorough knowledge of gynæcological diagnosis. At 5 p.m. on Tuesdays and Thursdays, the Master conducts a special class in practical obstetrics, including palpation, auscultation, pelvimetry, and operations on the phantom. Lady medical students can reside in the hospital. Extern assistants are appointed from among the students as vacancies occur. These most responsible appointments afford the students every opportunity of making themselves competent in practical midwifery. Candidates for the diploma of the Coombe Hospital must have their names on the books of the hospital for six months, during which time they must attend as frequently as possible, and be present at 30 deliveries. They then present themselves for examination, and if found qualified receive the diploma. The catering for the residents is in the hands of a competent housekeeper. Board and lodgings, £1 1s. per week. The students' quarters are comfortably furnished.

Fees.—Extern pupils (for full course of six months), £8 8s. This includes one month's residence in hospital. Intern pupils—one month, £4 4s.; each consecutive month, £3 3s.; six months and L.M. diploma, £18 18s. Board and lodging in the hospital, 18s. per week. Lady students, intern—one month, £5 5s.; each consecutive month, £4 4s.; six months and L.M. diploma, £18 18s. Registration fee, 10s. 6d. There is no extra charge for attendance at any of the dispensaries. Certificates of attendance from this hospital are accepted by all the licensing bodies.

* National Maternity Hospital.—This institution, under the joint mastership of Sir A. Horne and Dr. R. White, is situated in Holles Street.

*Cork Street Fever Hospital contains 266 beds. It is supported by subscriptions, an annual Government grant, and capitation grants for patients. Regular clinical instruction is given during the winter and summer sessions to those who desire a special course in fevers. There are also courses for the Diploma in Public Health. All particulars may be obtained on application to the Medical Superintendent.

The National Children's Hospital for the treatment of all non-infectious diseases peculiar to children, with which the Pitt Street Children's Hospital, founded in 1821, was amalgamated, contains 45 beds for the reception of cases of deformity and all other forms of surgical disease. There is a general dispensary for extern patients held daily from 10 to 11. Operations are performed on Saturday at 12 o'clock. Practitioners and students can attend on application to Sir Lambert H. Ormsby, F.R.C.S.I.

*The Children's Hospital, Temple Street, Dublin (under the care of the Sisters of Charity).—This institution is the largest children's hospital in Ireland. There are 100 beds available for patients; about 1,000 cases are admitted to the wards annually; and about 7,000 or 8,000 seen in the dispensary. A new operating theatre has recently been opened. It is fitted and furnished in the best possible fashion for present-day surgery. Special attention is given to orthopædic surgery.

The hospital is recognised for clinical instruction in the diseases of children by those licensing bodies which require a certificate of instruction in this important branch of medical education. A nursing home is in connection with the institution, and trained nurses are always available for private cases. Senior students or others requiring a post-graduate course at the hospital should apply for full particulars to Dr. M. C. Staunton, hon. sec., or to any member of the staff.

The Incorporated Orthopædic Hospital, Ireland.—This hospital was founded in 1876, and contains 80 beds. It is available for every class of deformity Particulars may be obtained from the Secretary, at the Hospital.

The Royal Victoria Eye and Ear Hospital, Adelaide Road.—This hospital, which was opened in March, 1904, is an amalgamation of St. Mark's Ophthalmic Hospital and the National Eye and Ear Infirmary. The hospital contains 80 beds. Clinical instruction in diseases of the eye and ear, including the use of the ophthalmoscope and operations, is given daily from 10 till 1. Special classes for practical instruction in the use of ophthalmoscope, &c., and for the demonstration of cases, are formed from time to time.

The Incorporated Dental Hospital, Lincoln Place.—This hospital is the only special dental hospital in Ireland. It is officered by a strong staff of the leading dental surgeons of Dublin, and has a large *clientèle* and extensive practice among the Dublin poor. The fees are £12 12s. for each year's Dental Hospital practice, and proportionately smaller fees for shorter periods for surgeons and medical students. The term of pupillage in mechanical dentistry required by the various licensing bodies may be taken in the recently enlarged Hospital Laboratory. Particulars may be obtained from the Dean.

The City Hospital for Diseases of the Skin and Cancer, Holles Street.—Senior students are admitted free to the practice of this hospital, which has a large out-patient attendance, with 15 beds for intern cases. Classes of instruction will be given at regular intervals during the winter and summer sessions in the use of the Finsen light, X-rays, high frequency currents and radium, with demonstrations on (1) the production and use of the Röntgen rays, (2) electric currents, direct and alternating, with description of resistances, rectifiers and transformers; (3) accumulators, their construction, use, and methods in charging; (4) vacuum tube, choice of tube for particular kinds of work; fluorescent screen, and how to localise foreign bodies.

BELFAST HOSPITALS.

Royal Victoria Hospital.—Established 1791; incorporated by Royal Charter, 1875 and 1898. New hospital opened, September 17th, 1903. 300 beds; Convalescent hospital, 22 beds; Children's Hospital, 33 beds; Consumptive Hospital, 10 beds.

Clinical instruction in medicine and surgery is given each morning by the staff.

*Mater Infirmorum Hospital.—Established 1883. 160 beds. The New Mater Hospital, which was erected at a cost of over £50,000, was formally opened on April 23rd, 1900. During the year the intern patients numbered 1,525; accidents, 3,762, and cases treated in the Dispensary, 22,597; 389 surgical operations were performed. The total number of patients who received treatment was 27,884, being an increase of 1,517 as compared with the year 1904. A notable feature is in the number of accident cases, as the hospital is conveniently situated in proximity to a large working-class population, and within easy reach of most of the public works.

The Belfast Maternity Hospital (Incorporated).—Established 1794. 30 beds.—The practice of the Maternity Hospital, the certificate of which is recognised by all the universities and colleges, &c., is open to students. The fee for the session is £2 2s. Resident nurses are also received for training for a period of six months, and a diploma given which is recognised by public bodies. The hospital course is also recognised by the Central Midwives Board. Conditions for such on application to the Matron. During the year 1911, 567 patients were treated in the hospital, and 556 patients at their own homes. Besides this, 360 patients were dealt with in the extern gynæcological department. Clinical lectures and bedside demonstrations are given by members of the staff during both the winter and summer sessions. Students wishing to attend should apply to Dr. H. D. Osborne, 32 Lonsdale Terrace, Belfast, Hon. Secretary to Medical Staff.

Note.—Hospital was rebuilt in 1904 and removed to new premises in Townsend Street. A Resident Surgeon is elected periodically.

*Ulster Hospital for Children and Women, Mountpottinger, Belfast, is the only hospital in the large part of the city situated on the County Down side of the river. It is placed in a working-class district, and has a great field for its charitable operations. There are in the hospital about thirty beds for children and ten for women. There is an extern department for children open every week-day, except Saturday, from 9 till 10, and for women at 10.30, and a special department for diseases of the eye, ear, and throat on Tuesdays and Fridays from 9 till 10. During the summer and winter sessions, clinical instruction is given to students daily, operations being chiefly performed on Wednesday and Thursday. There is a resident midwife for extern work, and every facility is afforded students for attending their cases in the district.

Hospital for Sick Children (Incorporated), Queen Street.—This institution, erected by voluntary donations, and supported by voluntary contributions, was opened for the reception of patients on April 24th, 1879 It consists of a medical ward with twenty-eight beds, and one of a similar size for surgical cases. It is strictly non-sectarian in its principles, and is open to all denominations. Children from birth to the age of 12 years, and not suffering from contagious disease, are admissible as in-patients. A large extern clinic is conducted in the out-patient department between the hours of 9 and 10 a.m., where children from birth to 14 years are attended to. An operating theatre has been found necessary in the extern department, and has been erected. During the winter session systematic courses of lectures and demonstrations in the medical and surgical diseases of infancy and childhood are delivered in the wards on Wednesday and Saturday of each week at 9 a.m. At the close of the session an examination is held, and a gold medal awarded if sufficient merit has been shown. A Convalescent Home is maintained at Carrickfergus, Co. Antrim, in connection with the Hospital.

Ophthalmic Institution and Eye and Ear Hospital, Great Victoria Street, Belfast.—Established 1844. New hospital erected, 1867. Operation theatre added, 1902. New extern department, 1909. This hospital is situated on the main road between Queen's College and the Royal Victoria Hospital. It contains about 30 beds for intern patients, and a large extern department. The latter is open on Monday, Wednesday and Friday at 10 o'clock for eye cases, and on Monday and Thursday at 10 o'clock for ear cases. Special courses of instruction are given during the winter and summer sessions, but students can enter at any time, and can always obtain plenty of practice in ophthalmoscopic work. Full particulars may be had from Dr. J. Walton Browne, 10, College Square, N., Belfast.

Ulster Eye, Ear, and Throat Hospital.—Established 1871. New hospital opened 1874. 30 beds.

CORK HOSPITALS.

*North Charitable Infirmary.—Established 1774. 110 beds. Special wards for treatment of diseases of women and children. The extern department is largely made use of, and the number of accidents treated is very large. Clinical instruction is given daily from 9.30 a.m. to 12 noon. A new and thoroughly up-to-date operating theatre has recently been added at considerable expense.

Cork South Infirmary and County Hospital.—Founded 1773. The hospital contains 100 beds, available for clinical instruction, 40 medical and 60 surgical. There are also special wards devoted to the treatment of diseases peculiar to women and children, and a large medical and surgical extern department.

Clinical instruction is given daily during the session from 9.30 to 11.30, in both the medical and surgical wards, and clinical lectures are regularly delivered.

Students are regularly instructed in the methods of using the rays by practical demonstration on the cases requiring their use.

For further particulars apply to Norman I. Townsend, hon. sec.

Victoria Hospital for Women and Children.—Established 1874. 70 beds. A large amount of work is done in this hospital to relieve the poor of Cork, Kerry, and other counties.

* County and City of Cork Lying-in Hospital.—Established 1798. 17 beds.

* Eye, Ear, and Throat Hospital, Western Road.—Incorporated 1898. 35 beds. In-patients treated during year, 454; out-patients, 4,238. Clinical Instruction is given during college session. Special demonstrations in the use of the ophthalmoscope, laryngoscope, &c., are given from time to time.

* Fever Hospital and House of Recovery.—Established 1801. 110 beds.

* Maternity.—Established 1872.

* Mercy Hospital.—Established 1857. 80 beds.

GALWAY HOSPITALS.

* County Hospital.—Established 1786. 60 beds.

* No answer to our request for information received from these hospitals.

IRISH PUBLIC SERVICES.

The Poor-law Medical Service.

For several years past the unsatisfactory nature of the Irish Poor Law Medical Service, as a career for young practitioners, has been evident. In addition to the petty annoyances, the laborious and harassing duties, and the ever-increasing amount of clerical work which the new orders of the Local Government Board impose from time to time, the medical officers are underpaid, their salaries being totally out of proportion to the duties discharged, and in the majority of rural districts barely sufficent to cover the out-of-pocket expenses, such as are incurred in the keep of a horse and man, and other servants. So strictly is the poor law medical officer bound to the discharge of his duties that unless incapacitated by sickness or other cause, or with the permission of the guardians expressly granted, he cannot leave his district for a single day, even if he makes provision for the performance of his duties in his absence by a brother practitioner. It is right to point out to young practitioners the following facts: (1) That the Poor Law Medical Service is one in which there is no promotion. (2) That it is a service where few facilities exist for original research, and still less for further medical culture, especially in the rural districts. (3) That, while medical education has become wider in its requirements and more costly and difficult to procure, almost the same rate of payment as was given to less educated men forty years ago is still offered, and this, too, at a time when lucrative private practice is more difficult to obtain. (4) That there is no compulsory superannuation, and, as a consequence, many old and infirm men are forced to remain in the service long after they have become unfit to discharge the duties, seeing nothing but extreme poverty and perhaps the workhouse itself staring them in the face.

There are about 160 workhouse and about 810 dispensary medical officers. The salary is said to average about £114.

The dispensary medical officer is also *ipso facto* the registrar of births, marriages, and deaths, and medical officer of health for the district, under the Public Health Act, passed in 1873 and amended in 1878. The former office, in country districts, yields between £5 and £10 a year, and the emoluments of the latter appointment in very few cases reach £20, averaging about £12. The medical officer is also vaccinator for the locality, and is required to vaccinate everyone who applies. For each patient a fee of 2s. is paid, along with his salary, by the guardians, and the sum total of these fees varies, according to the populousness of the district, from £4 to £100, an average for the provinces being about £10.

Qualifications.—The qualifications required by the Local Government Board are a licence in surgery, in medicine, and in midwifery; but registration in the "Medical Register," if effected since the passing of the Medical Act, in 1886, fulfils all requirements. Candidates must also be 23 years of age. Candidates recently qualified must possess a certificate of competence in vaccination.

Duties.—The duty of the dispensary doctor is twofold. He has to attend his dispensary or dispensaries on a given day or days in the week. He has also to visit at any hour of the day or night a sick person for whose relief a visiting ticket has been issued and to continue his attendance as often as may be necessary to the termination of the case. Moreover, he has many books to keep and a multitude of returns to make, and in most districts he has to make up all the medicines for the poor.

Workhouse Hospitals.—The number of unions in Ireland is 159, to each of which is attached one or more medical officers, appointed and controlled by the board of guardians in the same manner as the dispensary medical officer. The salary is about the same as that of the dispensary doctor, and the duties of a more easy and satisfactory description, inasmuch as they are confined to daily attendance at the workhouse hospitals, and no night visits out of doors or long journeys across the country are involved.

The Irish Lunacy Service.

This service, at present, affords a comfortable livelihood for 22 resident medical superintendents and 32 assistants. The superintendents receive salaries and allowances ranging, according to the number of inmates of the asylum, from £500 to £1,000 a year, and the assistants receive salaries and emoluments averaging about £200 to £300 a year. There are also a few visiting physicians receiving about £120 a year, but this class of officer is being allowed to die out, and no new appointments will be made. The superintendents and assistants must devote their whole time to their duties.

The appointments of medical superintendents are in the hands of the asylum committees, with the proviso that no one shall be appointed who is not a registered practitioner with five years' service as assistant. The assistant is also appointed by the committee. In addition to these officers, there are, in certain larger asylums, clinical residents, who receive about £50 a year and full allowances. These appointments afford excellent introduction to the higher places in the service.

Tuberculosis Service.

Most of the county and county borough councils are proceeding to appoint tuberculosis officers to carry out work under the Tuberculosis Prevention Act (1908) and the National Insurance Act (1911). The duties proposed are usually (1) to act as superintendent of the county sanatorium; (2) to conduct one or more tuberculosis dispensaries; (3) to act as consultant with practitioners in regard to tuberculous patients; (4) to conduct a bacteriological laboratory; (5) to act as adviser to the local insurance committee and the county council in regard to tuberculosis; (6) to organise and conduct anti-tuberculosis work generally in the county or county borough.

The tuberculosis officers must give their whole time to their duties. The salaries offered vary from £350 to £500 a year, with an allowance for expenses. The lower figure must be regarded as quite inadequate, and candidates before applying for such posts should satisfy themselves that the conditions of service have been approved by the local medical profession.

National Insurance Work.

The National Insurance Act (1911) has provided a certain amount of employment for medical men. As the question of extending the medical benefit of the Act to Ireland is still under discussion, all present arrangements are of a purely temporary character. The conditions of many of the appointments made by the Insurance Commissioners are contrary to professional ethics, and before accepting any appointment in connection with the Insurance Act great care should be exercised to make sure that the conditions of service are satisfactory from a professional point of view. Inquiries on such matters may be directed to the Medical Secretary, Irish Medical Committee, Royal College of Surgeons, Dublin.

Other Appointments.

There are, in addition to those which we have mentioned, certain appointments open to medical practitioners in special localities. They are:—

(1) Surgeoncies to the county infirmaries. (2) Attendance on the Royal Irish Constabulary. (3) Attendance on the Coastguards. (4) Factory Surgeoncies. (5) Attendance upon the depot soldiers who are not otherwise provided for. (6) Attendance on Postal Officials. (7) Prison Surgeoncies.

In each county is an infirmary or public hospital, to which one or more surgeons are appointed. In most cases the surgeon receives a salary of about £120 a year, and the appointment is in the hands of the infirmary committee, which is nominated by the county council. Some of the recent appointments have been honorary. The position is a pleasant one, and gives scope for modern surgical work. It is considered the best introduction to county consulting work.

The Constabulary are paid for at the rate of 2s. per month for each member of the force on duty in the district, including the wives and children of the men, but not of the officers. This includes the supply of medicines. The appointment to this position rests with the Inspector-General of the Royal Irish Constabulary, who usually acts upon the advice of the local district inspectors as to the convenience of the men, and, of course, the emoluments depend on the number of Constabulary stations and the number of men in each.

The Coastguard Service.—The duty of the medical officer is to attend the men when sick and to examine candidates either for admission or for superannuation. The fees vary from 5s. to 2s. 6d. per visit. The appointments rest with the Admiralty, but are usually secured for the local Poor Law medical officer. The emoluments depend on the number of stations and men, which are now very few.

Factory surgeoncies are in the gift of the Chief Inspector of Factories in Whitehall. There is a set scale of payment by the factory owner to the inspector for this work, but we believe it is not adhered to, and, in some districts, at all events, the emolument is a matter of arrangement. The amount depends upon the size of the factory, the position being, in Dublin or Belfast, or in other large manufacturing centres, a lucrative one, but in other places scarcely worth taking. The attendance on the military depôts is not worth mentioning.

Attendance upon postal servants is badly paid, except in the large towns, and the inspecting and sanitary duties are onerous.

Surgeons to the prisons are appointed by the Lord Lieutenant. The salaries for visiting surgeons vary from about £40 a year to £150. In the larger prisons there are whole-time surgeons.

Scotland.

In London the hospital is the unit of the medical school; in Scotland medical education is centred round the four Universities. It is very much a matter of convenience, or of fancy, which University the student seeks. Naturally, to those with no local ties, the prestige attaching to the Edinburgh degree proves attractive, and the number of graduates from overseas who attend the University is proof that its reputation is not declining. In addition to the University degrees, one other qualification to practise can be obtained in Scotland—the joint licences of the Royal College of Physicians, the Royal College of Surgeons, Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow. The standard of examination for the triple qualification (as it is called), though lower than that of the Universities, is yet high enough to test the abilities of the candidates, if one may judge from the number of rejections. The standard, too, is being gradually raised. Of late years there has been a falling off in the number of candidates for the triple qualification, and the majority are not Edinburgh-trained students, but hail from other schools. The diminution of the number of Scottish students is generally ascribed to the operations of the Carnegie benefaction enabling men who formerly would have been unable to do so, to take the University course. One characteristic feature of the Scottish medical schools is the existence, side by side with the University, of extra-mural schools, independent in every respect of the University, and recognised by the latter as schools whose classes qualify for graduation. The extra-mural school has suffered, just as the triple qualification has, from the Carnegie bequest, and there is reason to believe that under modern conditions it is unlikely to occupy such a prominent place as in the past. The proposed introduction by the Universities of a composition fee for the medical curriculum is viewed by the extra-mural lecturers with dislike, because it is feared that if it comes into effect the number of extra-mural students will again decline. (*a*)

It must also now be admitted that the tendency towards concentration of teaching under the ægis of the University is stronger than in the past. The increased cost of equipment for teaching, in particular, renders it difficult, if not impossible, for an unendowed school to compete with a University. This applies especially to the preliminary and purely scientific subjects of the curriculum up to and including physiology and pathology. It is doubtful whether it will long remain possible for such subjects to be adequately taught by private individuals who have to depend largely or wholly on class fees for their remuneration.

During the last few years the medical curriculum has been subjected to the most careful scrutiny, and it has undergone, and is still undergoing, great changes for the better. An agreement has lately been entered into by the managers of the Infirmary and the University of Edinburgh, under which the facilities for clinical teaching, and for pathology, are much enhanced. It may now be said, without fear of contradiction, that the education given in the Scottish schools generally has no need to fear comparisons. The dispensary system is peculiar to Scotland; what we know as a dispensary differs entirely from a dispensary in the English sense of the word. A dispensary is an out-patient clinic, separate from any hospital, staffed by honorary medical officers, and attended for instruction by students. Not the least important part of the student's curriculum is his attendance for several months on outdoor patients in their own homes under the same conditions as obtain in practice among the lower working classes. University students have the privilege of working under extra- as well as intra-mural teachers, while men going up for the triple qualification are limited to the latter. It is not uncommon, however, for a man to come up intending to take the licence, and to change his mind and go in for a degree, or *vice versâ*, and this can usually be done without much trouble or added expense, provided the change is made early in the course. The maternity training is still a weak spot in the Edinburgh curriculum, and many students are in the habit of going to Dublin or Glasgow for their practical midwifery. Great difficulties apparently stand in the way of making the work in Edinburgh what all its teachers would like—among them the material which is required for training midwives under the new Act—and though amalgamation of various institutions, and the opening of a residency in connection with the maternity hospital, have done something to improve matters, they have, to a certain extent, fallen short of what was hoped. When all is said and done, however, the Scottish graduate or diplomate receives an excellent training in his profession, and it can no longer be said that his course, though good in theoretical subjects, is defective in practical work. It is impossible to make any very definite statement as to the relative cost of a medical education in the different schools, as compared with London and Dublin, as so much depends on the extra classes taken out, the mode of living, and so on. The minimum inclusive fees for the licence are £120, for the M.B. degree about £146; but almost every student finds it practically necessary to attend additional classes.

THE CARNEGIE TRUST.

Through the munificence of Mr. Andrew Carnegie, LL.D., payment is now made " of the whole or part of the ordinary class fees exigible by the Universities from students of Scottish birth or extraction, and of sixteen

---

(*a*) This aspect of the composition fee is dealt with in a separate article on page 300.

wa
size

years of age or upwards, or scholars who have given two years' attendance, after the age of fourteen years, at State-aided schools in Scotland, or at such other schools and institutions in Scotland as are under the inspection of the Scottish Education Department."

The Trust provides for the payment of the class fees of the above students proceeding to graduation in medicine or science. Application for payment of class fees under the conditions of the Trust should be made to the Secretary, Mr. W. S. McCormick, Merchants' Hall, Edinburgh.

UNIVERSITY OF EDINBURGH.

Four degrees in medicine are granted; Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The first two must be taken together, the last two may be taken separately.

No one is admitted to the degrees of Bachelor of Medicine and Bachelor of Surgery who has not been engaged in medical study for five years after passing a preliminary examination in general knowledge in accordance with the medical ordinances. A degree in Arts or Science of a British or other recognised University is held to supersede such preliminary examination. The subjects included in this general examination are English, Latin, elementary mathematics, and Greek, or French, or German.

The *annus medicus* of each year is constituted by at least two courses of not less than one hundred lectures each, or by one of such courses, and two courses of not less than fifty lectures each, exclusive of the clinical courses. Two years of the five must be spent at the University, the remaining three years at any other Medical School recognised by the University Court.

During the first four years the student must attend botany, zoology, physics, practical chemistry, practical physiology, practical pathology, and medical jurisprudence during courses of not less than 2½ months each; public health, not less than forty lectures; practical anatomy, during two courses of not less than five months each; chemistry, anatomy, physiology, pathology, surgery, materia medica, medicine and midwifery during courses of not less than five months each. He must attend a course of twenty-five lectures on practical pharmacy, or have dispensed drugs for a period of three months in a recognised hospital or dispensary. He must attend a nine months' course in clinical medicine and in clinical surgery. During the fifth or final year he must be engaged in clinical study for at least nine months. In all, before graduation, he must have done hospital work for at least three years, and have acted as clerk in the medical and surgical wards and attended for six months the practice of a dispensary, or of a physician and surgeon. He must also have studied (1) operative surgery; (2) mental diseases; (3) *post-mortems*, fevers, diseases of the eye, diseases of children, of the ear, nose and throat, and of the skin; (4) vaccination; (5) practical anæsthetics.

He must attend at least 25 cases of labour under the superintendence of a registered medical practitioner or 12 such cases, and, for at least three months, the practice of a midwifery hospital.

Each candidate is examined both in writing and *vivâ voce*:—

1. On zoology, botany, physics and chemistry.
2. On anatomy and physiology.
3. On pathology, and materia medica and therapeutics.
4. On medicine, surgery, midwifery, forensic medicine, and public health.

The order of examination (for students beginning in winter) is as follows:—Physics, end of first half of first winter; Chemistry, end of second half of first winter; Zoology and botany, end of first summer; Physiology, end of second summer; Anatomy, end of first half of third winter; Practical materia medica, end of second half of third winter; Pathology, end of third summer; Materia medica, end of second half of fourth winter; Medical jurisprudence and public health, end of fourth summer; Midwifery, Medicine and Surgery, end of fifth winter; Clinical medicine, surgery, and gynæcology, end of fifth summer. An interval of 3 months must elapse between the date of passing the systematic subjects and the date of appearing for the clinical subjects.

The degree of Doctor of Medicine may be conferred on any Bachelor of Medicine and Bachelor of Surgery, who is of the age of twenty-four years, and who produces a certificate of having been engaged, subsequently to his having received the degree of M.B. and Ch.B., for one year in attendance on a hospital, or in scientific work bearing directly on his profession, or in the military or naval medical services, or for two years in practice other than purely surgical. The candidate shall submit to the Faculty of Medicine a thesis on any branch of knowledge comprised in the professional examinations for the degrees of Bachelor of Medicine and Bachelor in Surgery. The candidate will also be examined in clinical medicine and must show practical acquaintance with advanced methods of diagnosis; he may take gynæcology, mental diseases, or diseases of children for one of his three cases. The degree of M.D. is conferred on holders of the degrees of M.B., C.M. (Old Regulations) on the submission of a thesis approved by the Medical Faculty, provided that the candidate has passed the preliminary examination in the subjects of Greek and logic or moral philosophy. Should the candidate elect to do so, he may, however, take the M.D. degree under the new regulations, *i.e.*, substituting an examination in clinical medicine for that in Greek and logic. This course is usually pursued by those who did not pass in these subjects with the rest of their preliminary examinations.

The regulations for the degree of Ch.M. are very similar.

Fees:—The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery is twenty-two guineas. The fee for the degree of Doctor of Medicine or of Master of Surgery is ten guineas (Old Regulations, £5 5s.).

The total expense of the curriculum, including examination and matriculation fee, is about £146.

Among scholarships, &c., open for competition during the session 1913-14, are the following:—Vans Dunlop scholarships value £100; Buchanan scholarship in midwifery, value £40; Mouat scholarship in practice of physic, £57; Allan Fellowship in clinical medicine and surgery, £55. There are also a great many other bursaries, fellowships and prizes open during the session of 1913-14 and for the details governing entry for these the University Calendar (James Thin, South Bridge, Edinburgh) should be referred to.

Graduation in Public Health.—Degrees (B.Sc. and D.Sc.) are also conferred in Public Health. Candidates must be graduates in medicine and must matriculate for the year in which they proceed for examination. They must (1) have worked at least twenty hours a week during a period of eight months in a recognised Public Health laboratory—five of these months must be spent consecutively in the Public Health Laboratory of the University of Edinburgh; and (2) have attended a course of lectures on physics in addition to that qualifying for graduation in medicine, and one on geology.

Candidates for the second examination are not admitted until eighteen months have elapsed after having passed M.B., Ch.B., or sooner than six months after the first examination. They must have attended two courses of Public Health, one dealing with medicine, the other with engineering in relation to public health. They must also have studied practical sanitary work under a Medical Officer of Health for six months, have had three months' instruction in a fever hospital, and three months' instruction in mensuration and drawing.

Fees for Science Degrees: B.Sc., first examination, £3 3s.; B.Sc., second examination, £3 3s.

Diploma of Tropical Medicine.—The University Diploma of Tropical Medicine and Hygiene is conferred only on those possessing a degree in medicine. The course includes practical bacteriology, tropical diseases and hygiene, the zoological character and life history of disease-carrying insects and venomous animals, clinical instruction at an hospital for tropical diseases. The examination is held in January and July, the fee being £ 4s. A special certificate in Tropical Diseases is also granted under less stringent regulations, and after a shorter course.

Diploma in Psychiatry.—The course extends over one year, during which candidates must attend classes on (1) Anatomy and (2) Physiology of nervous system, (3) Pathology, (4) Bacteriology in relation to nervous system, (5) Psychology, (6) Clinical Neurology, (7) Psychiatry, (8), Clinical Psychiatry. There are two examinations, one on anatomy, physiology, pathology and bacteriology; the second on the remaining subjects. The fees amount to about thirty-seven guineas.

University Hall, Edinburgh.—In Edinburgh there are numerous halls of residence for under-graduates. In each house there are private studies with or without bedrooms, and common sitting and dining rooms. The charges are moderate. It is a satisfactory indication of the comfort of the Hall that many graduates live in it and are willing to help or coach the undergraduates for moderate fees. To gain admission two references must be produced from past or present residents, or other suitable person. These are considered and voted on at a house meeting, and any unruly member may be expelled by a similar meeting of the residents

Medical School for Women.—Classes for women are carried on in the College of Surgeons and the New School, by Lecturers recognised by the University.

Information may be obtained, on application to the Dean, School of Medicine of the Royal Colleges, College of Surgeons, Edinburgh. Session begins October 1st, 1913. The classes qualify both for the Edinburgh University degree and for the Licence of the Triple Board, and are for women alone. The University of Edinburgh does not recognise certificates presented by female candidates for mixed classes without special cause shown. Women students are eligible for the benefits of the Carnegie Bequest.

UNIVERSITY OF GLASGOW.

The University of Glasgow is both a teaching and an examining body, but admits to examination only those candidates whose course conforms to its own regulations. Within certain limits provision is made for accepting instruction given by recognised medical schools and teachers; but not less than one half of the subjects other than clinical must be taken in this or some other recognised University entitled to confer the degree of M.D., and at least two years of the course must be taken in Glasgow University. Four degrees, open both to men and to women, are conferred—M.B. and Ch.B. (always conjointly), M.D. and Ch.M. A preliminary examination must be passed in (1) English, (2) Latin, (3) Mathematics, and (4) an Additional Language, namely, Greek, French, German, Italian, or other approved language, with possible options to students whose native tongue is not English, and, on passing, students must register in the books of the General Medical Council. For M.B. and Ch.B. a curriculum of five years is required. A syllabus with full details of the curriculum and of the preliminary examination may be had, post free, on application to the Registrar.

The fees for M.B. and Ch.B. are £23 2s.; for M.D. £15 15s., and for Ch.M. £15 15s. For hospital attendance there is an initial fee of £10 10s., with a further fee of £3 3s. for each winter session, and £2 2s. for each summer session, of clinical instruction. There are three very extensive general hospitals in the city, which afford exceptional opportunities for clinical work, while the Royal and other asylums, the City Fever Hospitals, the Maternity Hospital, the Sick Children's Hospital, the Eye Infirmary, &c., give facilities for the study of special branches.

The degrees of B.Sc. and D.Sc. in Public Health and of B.Sc. in Pharmacy, are also now conferred. Of late the University has made considerable efforts to extend its laboratory accommodation and equipment, to augment its teaching staff, and to encourage post-graduate and research work. Within recent years there have been provided new laboratories in the departments of pathology, anatomy (costing £13,000), chemistry, and surgery (costing £9,900); while new laboratories, costing, with equipment, upwards of £50,000, have been erected for the departments of physiology, materia medica, and medical jurisprudence and public health.

Bursaries and prizes to the annual amount of about £1,000 are appropriated to medical students, including an Arthur bursary for women, £20 for three years.

Several bursaries open to students in any faculty are not infrequently held by medical students, and Scholarships and Fellowships to the annual amount of £1,600 may be held by medical students who have gone through the Arts course.

Queen Margaret College for Women. — Founded in 1883 (by the Glasgow Association for the Higher Education of Women, which was formed in 1877 with the object of bringing University instruction, or its equivalent, within the reach of women), Queen Margaret College in 1890 added to its faculty of Arts a School of Medicine for Women. This was organised entirely on University lines, and with the view of preparing for University degrees; and when, in 1892, in consequence of the Ordinance of the University Commissioners authorising the Scottish Universities to admit women to instruction and graduation, Queen Margaret College became the Women's Department of the University of Glasgow, its classes in medicine taken previously to its incorporation with the University were recognised as preparing for the degree. A full course of study for M.B. and Ch.B. is given by University professors and lecturers, with excellent facilities for hospital and dispensary work in the Royal Infirmary and other hospitals. A Hall of Residence for the students was founded in 1894. Fees for the classes at Queen Margaret College may be paid by the Carnegie Trustees; and several bursaries are open to women students of medicine.

The Winter Session begins on 13th October. The prospectus can be obtained from the Mistress, Miss Melville, Queen Margaret College, Glasgow.

UNIVERSITY OF ABERDEEN.

The University of Aberdeen possesses under its charters the amplest privileges claimed or enjoyed by any academical institution. It confers degrees in the five faculties of Arts, Science, Divinity, Law, and Medicine. It also grants diplomas in Public Health, and Agriculture. It is, moreover, a teaching body equipped with twelve distinct chairs in the various branches of medicine and surgery. The majority of the professors devote their whole time to the work of the chairs. There are fully-equipped laboratories, the accommodation for which has recently undergone considerable extension. The degrees of M.B. and Ch.B. are conferred together; they cannot be obtained separately. The curriculum of study is nearly the same as in the University of Glasgow; the regulations in the preceding columns will therefore apply here. Two years must be passed at Aberdeen. With regard to fees, each candidate for the degrees of M.B. and Ch.B. must pay a fee of £5 5s. in respect of each of the first three professional examinations, and £7 7s. for the final examination. Total cost, exclusive of the fees for degrees, is about £130. Besides the Royal Infirmary students have the opportunity of attending several other local institutions where special courses of instruction are given. Perpetual fee for hospital practice £10. The professional examinations are held twice in each year, namely, in March and July, directly after the close of the winter and summer sessions.

Bursaries.—Bursaries, Scholarships, and Fellowships to the number of fifty, and of the annual value of over £1,180, may be held by students of medicine. (See "University Calendar.")

The Degree of M.D.—The degree of Doctor of Medicine may be conferred on any candidate who has obtained the degrees of M.B. and Ch.B., is of the age of twenty-four years, and has been engaged subsequently to his having received the degree of M.B. for one year in attendance in a hospital, or in scientific research bearing on his profession, or in military or naval medical service, or for two years in medical practice, and has presented a thesis which has been approved of by the Medical Faculty. Candidates are required to pass an examination in clinical medicine or another Department of Medical Science in addition to presenting a thesis. Similar regulations apply to a degree of Ch.M. (Master of Surgery).

A Diploma in Public Health is conferred after examination on graduates in medicine in any University in the United Kingdom. Regulations may be seen in the "Calendar," or obtained on application to the Secretary of the University.

Aberdeen Royal Infirmary.—This is a well-equipped institution, containing 250 beds, and affords excellent opportunities for clinical study to students at the Aberdeen University. The city, moreover, offers inducement in the way of cheaper living and comparative quiet to that obtained in Edinburgh and Glasgow, and will doubtless be preferred by some on this account.

ST. ANDREWS UNIVERSITY.

United College, St. Andrews, and University College, Dundee.

This University (session opens October 14th) grants the degrees of M.B., Ch.B., M.D., and Ch.M. The degrees of the University are open to either sex. For the degree of M.B., Ch.B., two of the five years of medical study must be spent in the University of St. Andrews; the remaining three may be spent in any University of the United Kingdom, or in any foreign, Indian, or Colonial University recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court. The preliminary examination and the professional examinations are of the same character as in the other Scottish Universities. A Diploma in Public Health is also granted by the University of St. Andrews to graduates in medicine of any University in the United Kingdom. Twelve months must elapse between the date of graduating in medicine and entering for the examinations for the diploma. The course of study required consists of (1) a six months' course of practical chemistry, bacteriology, and the pathology of diseases transmissible from animals to man in a laboratory of the University of St. Andrews; (2) six months' work with a medical officer of health; (3) three months' clinical instruction in infectious diseases. Subjects for first examination:—Chemistry, physics, bacteriology, and meteorology. Second examination:—Sanitation, sanitary law, vital statistics, medicine in relation to public health.

University College, Dundee, was affiliated and made to form part of the University of St. Andrews in 1897, and the whole medical curriculum may be taken at the medical school of that College. The United College, St. Andrews, offers classes for the first two years of professional study.

Bursaries and Scholarships.

United College, St. Andrews.—Nine Taylour Thomson bursaries for women, of the annual value of from £15 to £25 each—tenable for three years—preference to women medical students. Two Malcolm bursaries of the value of £25 each, tenable by men or women, for five years. Seventeen additional bursaries, including two of £50, one of £40, one of £30, six of £20, one of £15, and six of £10, are open to competition by students of medicine, arts, or science.

University College, Dundee.—Twelve entrance bursaries of the value of £15 each, and fourteen second and third year's bursaries of the value of £20 and £15 are open to competition. Two fourth and two fifth year's bursaries of £20 each are open to students who take the complete curriculum in Dundee. These are all tenable for one year. Other bursaries, of which the patronage is vested in trustees, are available.

The fees for the complete course, exclusive of the examination fees, amount to about £130.

Preliminary Examination.—The preliminary examination in Medicine will take place at the United College, St. Andrews, on September 13th, 15th, 16th, 17th, and 18th. Each candidate must apply to the Secretary for a schedule, to be filled up and returned not later than August 31st. The subjects of examination are: English, Latin, Elementary Mathematics, and Greek, or French or German, and the fee is half-a-guinea.

Fees.—Clinical medicine and clinical surgery, £4 4s. winter session; clinical medicine and clinical surgery, £3 3s. summer session; clinical obstetrics, £3 3s. winter session; £2 2s. summer session.

Fees for Degrees.—Total fees for M.B., Ch.B., are the same as at other Scottish Universities—*i.e.*, 22 guineas (payable in instalments). Fee for the degree of M.D., and also for that of Ch.M., is 10 guineas in each case. For the Diploma of Public Health examinations the fee is £5 5s. for each of the two examinations.

Class Fees.—The fee payable in each of the following classes is 4 guineas, *viz*:—Chemistry, physics, zoology, botany, physiology, anatomy, materia medica, pathology, forensic medicine, and public health, medicine, surgery, and midwifery. The fee for the practical classes in these subjects is 3 guineas each. In clinical surgery and clinical medicine, the fee is £4 4s.; ophthalmology, diseases of the throat, nose, and ear, diseases of the skin, and mental diseases, the class fees are 2 guineas each. The fee for Public Health chemistry required for the D.P.H. is 7 guineas. A special class in Bacteriology is also held for the D.P.H. for which the fee is 3 guineas.

Dundee District Asylum.—The appointments include two qualified resident assistants and two resident clinical clerks. Clinical instruction is given.

Dundee Royal Infirmary.—Clinical instruction is given at the Infirmary which contains 400 beds, with an annual average number of over 4,000 in-patients, and an annual daily residence of 280, with special wards for maternity cases, diseases of women, diseases of children, diseases of the eye, diseases of the ear, throat and nose, cancer, incipient insanity, and for cases requiring electric treatment. Six resident qualified assistants and an outdoor obstetric assistant are appointed annually. Clinical clerks and dressers are attached to the physicians and surgeons, and students are appointed to assist in the post-mortem room. The instruction given at the Infirmary is recognised for purposes of graduation by the Scotch Universities, the University of London, the University of Cambridge, the Royal University of Ireland, and by the Royal Colleges of England and Scotland. Hospital Tickets for the Infirmary, £2 2s. each session, or £3 3s. a year. Perpetual, £10 in one payment, or £10 10s. by instalments.

Further information will be found in the Calendar of the University published by Messrs. Blackwood and Sons, Edinburgh, the "Calendar of University College," Dundee (obtainable from the Secretary), or can be had from the Dean of the Medical Faculty, Professor J. A. Kynoch.

THE COLLEGES.

The Royal Colleges of Physicians and of Surgeons of Edinburgh, and Royal Faculty of Physicians and Surgeons of Glasgow have arrangements by which the student may obtain the diploma of the co-operating bodies, and can register three diplomas under the Medical Acts—*viz.*, Licentiate of the Royal College of Physicians of Edinburgh, Licentiate of the Royal College of Surgeons of Edinburgh, and Licentiate of the Faculty of Physicians and Surgeons of Glasgow.

The three bodies grant their *single* qualifications only to candidates who are already registered as possessing another and opposite qualification in medicine and surgery as the case may be.

Regulations of the Conjoint Board of the Royal Colleges of Physicians and of Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons, Glasgow.—The candidate must produce certificates of having attended the following course of lectures, the certificate distinguishing the sessions and the schools in which the courses were attended.

Anatomy, six months; practical anatomy, twelve months; chemistry, six months; practical chemistry, three months; materia medica, three months; physiology, six months; medicine, six months; clinical medicine, nine months; surgery, six months; clinical surgery, nine months; midwifery, three months; medical jurisprudence, three months; pathology, three months. The candidates must also produce the following certificates:—(*a*) Of having attended six cases of labour under the superintendence of a registered practitioner. (*b*) Of having attended for three months instruction in practical pharmacy. The teacher must be a member of the Pharmaceutical Society of Great Britain, or the Superintendent of a laboratory of a public hospital or dispensary, or a registered practitioner, or a teacher to a class of practical pharmacy. (*c*) Of having attended for twenty-four months the medical and surgical practice of a hospital, containing eighty patients, and possessing distinct staffs of physicians and surgeons. (*d*) Of having attended for six months the practice of a public dispensary, or of having assisted for six months a registered practitioner. (*e*) Of having been instructed in vaccination.

First Examination, Fee £5.—The First examination shall embrace chemistry, physics, and elementary biology, and shall take place not sooner than the end of the first year, including a winter and summer session. Candidates who desire to enter for the first professional examination must produce certificates of attendance on chemistry, practical chemistry, anatomy, and six months' practical anatomy.

Second Examination, Fee £5.—The Second examination embraces anatomy and physiology and shall not take place before the termination of the summer session of the second year of study. Candidates must produce certificates of attendance on anatomy, practical anatomy, and physiology.

Third Examination, Fee £5.—Comprises the subjects of pathology, materia medica, and pharmacology and advanced anatomy.

Final Examination, Fee £15.—The Final examination embraces medicine (including therapeutics and medical anatomy, clinical medicine); surgery (including surgical anatomy and surgical pathology); clinical surgery; midwifery and gynæcology, medical jurisprudence and hygiene; and shall not take place before the termination of the full period of study.

Subjects of Preliminary Education: (1) English grammar and composition; (2) Latin, grammar, translation from specific authors and easy unseen translation; (3) (*a*) arithmetic, to vulgar and decimal fractions; (*b*) algebra, to simple equations; (*c*) geometry, to the first two books of Euclid; (4) elementary mechanics of solids and fluids, comprising the elements of statics, dynamics, and hydrostatics; (5) one of the following:—(*a*) Greek; (*b*) French; (*c*) German; (*d*) Italian; (*e*) any other modern language; (*f*) logic; (*g*) botany; (*h*) zoology; (*i*) elementary chemistry.

Qualification in Public Health.—The College of Physicians, in association with the Royal College of Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow, confers a certificate of competency in public health. The examinations are held in April and October. Fee, £10 10s.

For the special regulations of the Royal College of Surgeons of Edinburgh, intending candidates should apply to Mr. James Robertson, 48 George Square, Edinburgh; and for those of the Royal College of Physicians, to the Secretary.

The Fellowship of the Royal College of Physicians of Edinburgh is conferred only by election, and the candidate must have been a member of the college for at least three years, and have attained the age of twenty-seven years.

The Membership is conferred only on a licentiate of a college of physicians or graduate in medicine of a British or Irish University, provided he shall have attained the age of twenty-four years and shall have passed an examination on: (1) medicine, including therapeutics; (2) on one of the following optional subjects, *in which a high standard of proficiency is expected*:—(*a*) a department of medicine specially professed; (*b*) psychological medicine; (*c*) pathology; (*d*) medical jurisprudence; (*e*) public health; (*f*) midwifery; (*g*) gynæcology. The examination is of a searching character.

The fee for membership is 35 guineas, for fellowship 38 guineas, with a stamp duty of £25—£101 13s. in all.

The licence, or single qualification in medicine, is conferred on candidates who already possess a recognised qualification in surgery. The examinations for this licence are held on the first Wednesday of each month, save those of September and October, in medicine, materia medica, midwifery and medical jurisprudence. The fee is £15 15s., and intending candidates should communicate with the Secretary of the College at least eight days before the date of examination.

The Fellowship of the Royal College of Surgeons of Edinburgh is conferred (except under certain conditions as to age and professional standing) only on candidates who have passed a special examination, and have previously obtained a diploma from the college, or from either of the Colleges of Surgeons of England or Ireland, or the Royal Faculty of Physicians and Surgeons of Glasgow, or the surgical degrees of the Universities of Great Britain, and who are twenty-five years of age. The subjects for examination for those who are already Licentiates of the College are on the principles and practice of surgery, clinical and operative surgery, and one optional subject.

Those who are not Licentiates of this College: on principles and practice of surgery, clinical and operative surgery, surgical anatomy, and one optional subject; and in such supplementary subjects as have not, in an adequate manner, been included in the examination for the registrable surgical qualification possessed by such candidates, and which are required in the examination for Licentiates of this College.

The optional subjects shall embrace: (*a*) Surgery, special branches; (*b*) advanced anatomy and physiology; (*c*) surgical pathology and morbid anatomy; (*d*) midwifery and gynæcological medicine and surgery; (*e*) medical jurisprudence and hygiene; (*f*) practice of medicine and therapeutics. The examinations are written, oral, and practical. Three weeks' notice must be given to Mr. James Robertson, from whom full particulars as to certificates required may be obtained. The fee is £30 for those who hold the diploma of Licentiate of the College, and £45 to others (no stamp duty is payable on the diploma). Registered practitioners, aged not less than 40, who have been in practice for not less than ten years, and who have highly distinguished themselves by original investigations, may under special circumstances be elected without examination. Women are not admitted to the Fellowship of either college.

LICENCE.—The examination embraces the principles and practice of surgery (including operative surgery and surgical pathology), clinical surgery, and surgical anatomy, and shall not take place before the termination of the full period of study. Fee, £15 15s.

DENTAL DIPLOMA.—Every candidate for the dental diploma must have attended the general lectures and courses of instruction required at a University or an established medical or dental school recognised by the College as qualifying for the diploma in surgery. The fee is £10 10s.

Edinburgh Royal Infirmary.—Clinical instruction is afforded at this institution, which contains 900 beds under the supervision of professors of the University and the ordinary physicians and surgeons of the Infirmary. Special instruction is given on diseases of women, physical diagnosis, diseases of the skin, eye, ear, throat and teeth, and anæsthetics. Separate wards are devoted to venereal diseases, diseases of women, diseases of the eye, also to cases of incidental delirium or insanity, and three wards are specially set apart for clinical instruction to women students. Post-mortem examinations are conducted in the anatomical theatre by the pathologists. The perpetual fee, on one payment, £12; the annual fee, £6 6s.; half-yearly, £4 4s.; quarterly, £2 2s.; monthly, £1 1s. Separate tickets amounting to £12 12s. entitle the student to a perpetual ticket. No fees are payable for any surgical or medical appointment.

The appointments are as follow :—

1. Resident physicians and surgeons are appointed and live in the house free of charge. There is no salary. The appointment is for six months.

2. Non-resident physicians and surgeons (in the special subjects and for out-patient work) are appointed for six months. These appointments may be renewed.

3. Clerks and dressers are appointed by the surgeons and physicians. These are open to all students and junior physicians holding hospital tickets.

4. Assistants in the pathological department are appointed by the pathologists to conduct post-mortem examinations in the anatomical theatre.

Royal Hospital for Sick Children.—During the year three courses of clinical instruction are given by the staff of the hospital, who are recognised as University Lecturers on the subject. The course consists of clinical lectures, ward cliniques, attendance at *post mortems* and out-patient cliniques. Hospital tickets, £1 1s.

SCHOOL OF MEDICINE OF THE ROYAL COLLEGES, EDINBURGH.

The government of this school, established in 1505, is now vested in a board which is equally representative of the two Royal Colleges and the Lecturers, the school being styled "The School of Medicine of the Royal Colleges, Edinburgh." The present number of lecturers is fifty seven, of whom the greater number deliver qualifying courses of instruction of the same duration and scope as those delivered within the University, while a large number of non-qualifying courses on special subjects of interest to medical science, but which are not required for graduation, are delivered both in the winter and summer sessions. The students who attend the classes of the School of Medicine are largely students proceeding to the University degree, as well as those who are intending to take other diplomas, such as the triple qualification. For particulars apply to the Dean of the School, 11 Bristo Place, Edinburgh.

The minimum cost of the education in the School of Medicine for the triple qualification of physician and surgeon from the Royal Colleges of Physicians and Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow, including the fees for the joint examinations, is about £120, which is payable by yearly instalments during the period of study.

The Winter Session opens October 7th.

GLASGOW EXTRA-MURAL SCHOOL.

St. Mungo's College and Glasgow Royal Infirmary.—This college was incorporated in 1889 under its present title, being formerly known as the Glasgow Royal Infirmary School of Medicine. The Medical Faculty occupies buildings erected for the purpose of the medical school in the grounds of the hospital. The college is equipped with a complete electric light installation, and a powerful electric educational lantern. Attendance on the classes in St. Mungo's College qualifies for the medical degrees of the Universities and the medical and surgical colleges in accordance with their regulations. A syllabus, giving details as to classes, fees, &c., may be had on application to the Secretary of the Medical Faculty.

The Royal Infirmary, which is at the service of the College for teaching purposes, is one of the largest general hospitals in the kingdom. It has 600 beds available for clinical instruction, in addition to an ophthalmic department, and it has special wards for diseases peculiar to women, venereal diseases, burns, and diseases of the throat, nose, and ear. At the dispensary special advice and treatment are given in diseases of the eye, ear, teeth, and skin, in addition to the large and varied number of ordinary medical and surgical cases which in a great industrial centre daily require attention. Students at the college and hospital get the benefit of dispensary experience free of charge, and no better or wider field for seeing hospital practice and receiving clinical experience can be found than in the Glasgow Royal Infirmary.

Clinical instruction in midwifery is given in the fine new Maternity Hospital by Prof. Jardine.

Appointments.—All appointments are open. There are five physicians' and ten surgeons' assistants, who obtain free board and residence in the hospital and act in the capacity of house physicians and house surgeons. There is also a house surgeon for the ophthalmic department. These appointments are made for six months, and are open to gentlemen who have a legal qualification in medicine and surgery. Clerks and dressers are appointed by the visiting physicians and surgeons. From the large number of cases of acute diseases and accidents of varied character received, these appointments are valuable to students. Assistants are also appointed for the pathological department.

Fees.—The fees for Lectures, including hospital attendance necessary for candidates for the Diplomas of the English, Scotch, and Irish Colleges of Physicians and Surgeons, amount to about £80.

Royal Infirmary.—Fees : (1) Hospital attendance, dispensary, &c., perpetual ticket, £7 ; season ticket, six months, £2 2s. ; three months, £1 1s. Separate payments amounting to £7 7s. entitle a student to a perpetual ticket on returning previous season tickets. (2) Clinical instruction, six months, £3 10s. ; three months, £1 15s.

Dental Curriculum.—Students studying with a view to the dental diploma can obtain instruction in the following subjects : Physics, chemistry, anatomy, physiology, surgery, practice of medicine, and materia medica. The special dental courses may be obtained in the Dental School, of the Incorporated Glasgow Dental Hospital, 158 Renfrew Street, Glasgow. Particulars may be had from D. M. Alexander, Esq., Solicitor, 186 St Vincent Street, Secretary

Anderson's College Medical School, Glasgow.—Founded in 1800. The modern, excellently equipped buildings of this school are situated to the west of the entrance to the Western Infirmary, and within four minutes' walk of the University. Extensive laboratory accommodation is provided for practical anatomy, practical chemistry, practical botany, practical zoology, practical physiology, practical pharmacy, operative surgery and public health.

The various courses of instruction qualify for all the Licensing Boards in the United Kingdom, and for the Universities of London, Durham, Edinburgh, and Glasgow, under conditions stated in the calendars. The courses in public health (laboratory and lectures) are also recognised by the Universities of Cambridge, London, etc. Session opens 14th October, 1912. For syllabus, apply to the Secretary of the Medical Faculty, Anderson's College Medical School, Glasgow, W.

The Carnegie Trust pays the fees of students at Anderson's College on conditions regarding which particulars may be obtained from Sir W. S. McCormick, LL.D., Carnegie Trust Offices, Edinburgh.

Class Fees.—For each course of lectures (anatomy, ophthalmic medicine and surgery, aural surgery, diseases of throat and nose, mental diseases, and public health excepted), first session, £2 2s. ; second session (in Anderson's College), £1 1s. For practical classes (except anatomy, chemistry, and public health), namely, botany, zoology, physiology, pharmacy, operative surgery, first session, £2 2s. ; second session, £2 2s. *Chemistry.*—Lectures, £2 2s. ; practical chemistry, £3 3s. *Botany and Zoology.*—Reduced fees for lectures with laboratory work in botany or in zoology, during same summer session, £3 3s. ; for lecture class or practical class separately, in botany or in zoology, £2 2s. *Ophthalmic Medicine and Surgery* (including hospital practice), aural surgery, diseases of throat and nose, and mental diseases, fee for each course, £1 1s. *Anatomy Class Fees.*—Winter.—First session, lectures and practical anatomy, £5 5s. ; practical anatomy alone, £2 2s. Second session, lectures and practical anatomy, £4 4s. ; practical anatomy alone, £2 2s. Summer.—Regional course or special dental course (each including nervous system) and practical anatomy, £3 3s. ; regional anatomy course or special dental course alone, £2 2s. ; practical anatomy alone, £1 11s. 6d. ; osteology and practical anatomy, £2 12s. 6d. ; osteology alone, £1 11s. 6d.

Public Health Laboratory.—Fee for six months' course £12 12s. *Matriculation Fee.*—For the year, 10s.; for one class alone in winter, 5s.; for summer session alone, 5s.

Glasgow Western Medical School.—Owing to its situation in University Avenue (opposite the principal gate of the University and near the Western Infirmary), this school is conveniently placed for students desirous of taking extra-mural classes. Lectures and demonstrations are given, in the usual winter and summer sessions, on chemistry, anatomy, surgery, medicine, midwifery and gynæcology, ophthalmology and dermatology. Some of the classes qualify for graduation and for Scottish diplomas. The usual class fee is £2 2s. There is no matriculation fee. Further information may be obtained from the Secretary.

Glasgow Maternity and Women's Hospital.—This institution is of ancient foundation, but the present buildings, containing 104 beds, with a large out-patient department, were only opened five years ago. Erected with due regard for the most modern requirements, and staffed by physicians of reputation, it affords excellent facilities for acquiring a complete knowledge of the art and practice of obstetrics. There is also a students' residence in connection with the hospital, in which board and residence can be had at very moderate fees. Quarters are also afforded for lady students, board and lodging in the hospital costing but £1 7s. 6d. per week. The hospital fee is £5 5s. Full particulars from the House Superintendent.

Glasgow can boast of several other important medical institutions, such as the Western Infirmary, with a staff representative of the best in medicine and surgery of the second city of the Empire, and having no fewer than 500 beds. There is also the Victoria Infirmary, with 260 beds, in which leading specialities, such as ophthalmology, aural surgery, diseases of the throat, diseases of women, diseases of the skin, etc., are taught; the Glasgow Eye Infirmary, with 100 beds; the Royal Hospital for Sick Children, with 74 beds, etc.

SCOTLAND AND AN INCLUSIVE FEE IN MEDICINE.

The University of Glasgow has at present for its head, or Principal, the President of the General Medical Council. For one hundred and fifty years or more the Principal's chair at this University has been always filled by a clergyman, and Sir Donald Macalister is the first medical man who, in modern times at least, has held the position. It is quite fitting that Glasgow, which has for long been famous as a centre of medical education, should now have its University presided over by a member of the profession; but Glasgow, as a place for medical teaching, has owed not a little of its reputation to instructors whose lecture rooms were outside of the University, and in what are called the extramural medical schools. We have, however, begun this article by alluding to Principal Macalister, because he has seemed to be *facile princeps* in taking the leading part in Scotland in the movement for getting the Scottish Universities to adopt what is called an inclusive fee in medicine: that is a composite fee to be payable by a student (in five annual instalments) for his classes as a whole, instead of the separate fee at present payable for each class.

We have said that Principal Macalister has taken the leading part in Scotland in this movement, because the idea, so far as it can be traced, originated with the Treasury. In July, 1910, the Treasury, in announcing increased grants to the Scottish Universities, intimated that these would be made subject to two conditions, one of which was the institution of an inclusive fee, of uniform amount throughout the four Universities, for all the classes in each course of study.

To the Treasury's letter announcing the increased grant, the University of St. Andrews promptly replied, accepting the condition as to the institution of inclusive fees. No protest was made against the Treasury interfering with the internal administration of the University. Of course, in the case of St. Andrews, the question of an inclusive fee in medicine was not complicated by the presence of extramural lecturers, or, at all events, of any organised extramural school. It is to be noted that where extra-academical teachers exist, recognised by the University, a medical student has the option of taking, for graduation, one half of his classes with such teachers; paying for each class, to the teacher, the same fee as is chargeable for that class in the University. Thus, in the absence of any extramural school, the introduction of an inclusive fee was not so difficult at St. Andrews. Nevertheless, St. Andrews has reconsidered the matter, and has recently withdrawn from the position of accepting the inclusive fee system.

Now what are the advantages claimed by those who put forward the proposal for an inclusive fee in medicine? It is said that the medical student, instead of finding the cost of his curriculum increased as new classes are added to it, will have the total cost of his classes fixed, so that successive relays of students will all pay the same amount. This sounds well, from the point of view of the student, especially of the later student, who, unlike his earlier brother, may be getting something for nothing, namely, additional classes. But in the meantime there is a loss to his University, and if new compulsory classes are added, the inclusive fee would speedily require to be raised.

Again, it is said that an inclusive fee, payable as suggested, in yearly instalments, would equalise the student's payments for classes over the years of his curriculum, and obviate his having to pay, as he has at present, about two-thirds of his class fees in the first two of the five years of his course. This may be true; but if hospital fees, examination fees, etc., which bulk more largely towards the end of the student's curriculum, are taken into account, this argument is seen to disappear.

Following on the initial letter of the Treasury referred to, other correspondence between it and the Universities took place, in which the Treasury continued to urge upon the Universities the adoption of inclusive fees. In endeavouring to meet the wish of the Treasury, the courts of the four Universities held a conference in December, 1910, a second in January, 1911, a third in July, 1911, and a fourth in December of the same year. Little progress was made at these conferences in regard to arranging a uniform inclusive fee in Medicine, with which alone we are concerned. In fact, the proposal seemed so impracticable that Edinburgh University declined to attend a fifth conference, held on 20th June, 1912, at which, accordingly, only the other three Universities were represented.

The matter came before the General Councils of the Universities. At their meeting on 30th October, 1912, the General Council of Glasgow University passed a resolution protesting against the Treasury making the adoption of inclusive fees a condition of an increased grant to the Universities. Deputations from Edinburgh University and Glasgow University Councils proceeded to London to press this view on the Treasury and on Members of Parliament, pointing out what they considered to be an unwarrantable interference with the independence hitherto enjoyed by the Scottish Universities.

The special difficulty connected with the institution of an inclusive fee in Medicine in the Universities arises from the extramural schools and extramural teaching generally. Both in Edinburgh and Glasgow the extramural teachers have long been regarded as adding greatly to the efficiency and prestige of medical education in these places. But if an inclusive fee in medicine were adopted, which would be payable in every case to the University, the extra-academical teachers fear that it would have a tendency to make the student take all his classes in the University, notwithstanding any provisions that might be made for paying the extra-academical teacher out of the inclusive fee. It was only after years of severe struggle that the extramural schools obtained for the student the option of taking one-half of his classes outside of the University, and they naturally look with alarm and suspicion upon any interference with the student's present mode of paying his fees. The students themselves, through their representative councils, have expressed their particular desire that the extramural schools should not be injured. Notwithstanding that the Treasury has had pointed out to them that Lord Elgin's Committee on the Scottish Universities in their report (on which the Treasury proceeded) only suggested that "the institution of a composite fee deserves very careful consideration from the Universities of Scotland," the Treasury, from London, and Sir Donald Macalister, as, apparently, their advocate in Scotland, continue to press the adoption of an inclusive fee in medicine on these Universities, in total opposition to the views of Edinburgh University, of Edinburgh's large and well-equipped extramural Medical School, and of the Glasgow extramural schools. Now that the difficulties in the way of adopting the proposal have become apparent, and that St. Andrews University has also withdrawn its assent, perhaps the Treasury, looking further to the fact that Glasgow University Court is divided in opinion on the subject, will see the wisdom of withdrawing the pressure they are using, and thus close the chapter of interfering with the internal administration of the Scottish Universities.

Finally, it may be pointed out that for a student to be obliged to pay down the whole of his year's fees at one time, instead of, as at present, at the beginning of the winter and summer sessions respectively, would be to put a greater strain upon his resources, or those of his parents, and to disable him, in many cases, from taking extra or ancillary classes which he might otherwise have attended; and indeed might prevent him from proceeding with his studies altogether.

(END OF EDUCATIONAL NUMBER.)

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, September 6th, 1913.

Duodenal Ulcer

is not, so far, as familiar a form of disease as it is in England and America. In a paper delivered before the Aerbtlicher Verein, Frankfurt, Hr. Rosengart discusses the subject, and gives the reasons why in his opinion the disease is not such a household word here as it is in English-speaking lands. The speaker thinks the frequency of publications on the subject is due to the greater degree of specialisation that prevails in these countries, and especially in America. The centralisation of medical science has made greater progress across the Atlantic than in Germany. At the same time ulcus duodeni, he says, is much more frequently diagnosed in Germany than formerly. This was due to the completeness of diagnosis that had made itself evident during the last half-year. As said by Moynihan, there was no disease in which the symptoms were so typical, and the history was always of most extreme importance. The most remarkable symptom was the periodicity of the pain. The patient complained usually of trouble of very long standing. After a free interval, during which the patient felt well, the trouble came on suddenly and often lasted a long time, a sense of oppression, a feeling of pressure and heaviness in the epigastrium, and finally the characteristic pains, mostly to the right of the middle line, coming on about two hours after food, and slightly relieved by taking food afresh. Identical with this "hunger pain" was that which came on in the night. The objective symptoms were pain on pressure at the upper end of the right rectus muscle outside the middle line. There were occult bleedings per rectum, but these might be absent. The speaker had frequently found hypersecretion, in one case the so-called "twelve-hour remainders." Radiological examination was of great importance. The stomach generally appeared to be small and hypertoned. The stomach contents passed rapidly into the duodenum; the horizontal part appeared to be widened. The period of emptying, as well as the passage through the intestines, was generally shortened. According to Kreutzfuchs, the rapid emptying of the stomach (insufficiency of the pylorus) was due to increased secretion in the duodenum. Occasionally a Haudeck or Nischen symptom could be seen like bismuth outside the normal shadow of the duodenum; this pointed to perforated ulcer. During the last six months the speaker had met with 19 cases of the disease.

Hr. Güntzburg confirmed in general what had been stated by the reader of the paper. But he would observe that in his last 21 cases, in eight of which the diagnosis was confirmed either by operation or necroscopy, he had determined the fact of frequent occult hæmorrhage almost in every case. The chemical conditions of the gastric secretions were many-sided, but there was mostly hypersecretion. The duodenal sound mostly confirmed the conclusion of Kreuzfuchs that the disturbance of the acid reaction was due to the hypersecretion of the duodenum.

At the Gynæcological Society, Hr. Wolff related a case of

Rupture of the Uterus in a Cicatrix from a Case of Cervical Cæsarean Section.

The patient was a woman with a flattened pelvis, who had been delivered by cervical Cæsarean section. Two years after she again became pregnant. The os uteri dilated badly. After an hour the child's heart could not be heard, and its small parts could be plainly felt just under the skin. The patient's pulse became bad, and hæmorrhage appeared from the vagina. Laparotomy was now performed, when it appeared that rupture of the uterus had taken place in the line of the old cicatrix in the cervical portion. Microscopical examination showed that instead of muscular tissue the elastic fibres in the part were very plump and thick; the decidua reached to the serosa. It had been thought that union had taken place by first intention, but the finding of some old catgut sutures showed that that had not been the case. The insertion of the placenta near to the cicatrix was a point of importance. Inquiry into the literature of the subject had brought to light 48 such cases with 12 deaths.

Hr. Siegwart had operated in five similar cases. He believed that one should operate at once, and not wait until fœtal parts could be felt.

Hr. Bröse doubted whether the case had been one of cervical Cæsarean section at all. Hr. Jolly pleaded for sterilisation in every case of Cæsarean section.

Hr. Strassmann was of opinion that the knots of the sutures should be placed in the inside. When the sutures were extraperitoneal the peritoneum should be drawn over them and the knots turned in, as in the case of the Lembert suture.

Professor Bumm (the Chairman) did not consider the danger would be very great even if a cicatrix did give way.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

FRENCH DRAINS AND MALODOROUS FRANCE

To the Editor of The Medical Press and Circular.

Sir,—My card, which I enclose, will tell you that I am a frequent traveller and sojourner in France, and that I am particularly well able to appreciate the value of the editorial paragraphs under the above headings printed in your current number. It is amazing that this question, which is constantly being thrust before the eyes of newspaper correspondents in France, is practically ignored by the entire British

Press. The policy of pinpricks has long given way to the *entente*, and it seems that the neighbours, fearful to weaken their close friendship, are averse to offering any criticism in the least likely to wound each other's susceptibilities. No better service could, however, be done to France than the forcing to the front of the question of national hygiene, and if you, Sir, can arouse the interest of British Chambers of Commerce in France, and make it known that serious attention is being directed to it in England, you may put under an obligation all truly patriotic Frenchmen. It is the apathy of the French people that needs overcoming. The whole problem was expounded at the Congress of Hygiene in Paris in May last. The proceedings were reported in brief telegrams to the *Times*, but were not editorially noticed there, and were practically disregarded by other leading English journals. The most remarkable speeches were those delivered by M. Léon Bourgeois and M. Ribot, both ex-Prime Ministers. They viewed the question mainly from the patriotic standpoint. They both dwelt upon the necessity for France to maintain the numbers and quality of her populace. They both pointed out that the population remains stationary owing to the universal practice of restricting births, and they both laid stress upon the fact that the high comparative death-rate not only kept down the numbers, but implied lowered stamina in great masses who had survived the ordeal of infantile disease. It was further pointed out that the comparative mortality from tuberculosis and typhoid in Paris was three times greater than that of London, and at least twice as great as that of Berlin. The rate for deaths from tuberculosis in France was 22 per 10,000; in England and Germany this rate had fallen to 11. The general mortality in France was given as being from 18 to 19 per 1,000, while in England, Holland, and the Scandinavian countries it had fallen to about 14 per 1,000. M. Ribot, after fully describing the danger into which the nation must fall owing to the almost complete stoppage of its numerical increase, ended his speech with the following words: "This country is sick and it ought to be proclaimed aloud. The French race is withering. The people must be informed of the peril by which it is menaced. All the efforts of the Legislature and of the Government must be concentrated upon grappling with this peril."

If the almost complete disregard of public sanitation throughout France, the birthplace of Pasteur and a whole race of famous scientific hygienists, causes astonishment, it is difficult to decribe the feelings aroused in the minds of those who inquire into things that lie below the surface in "La Ville Lumière"—Paris. Every Parisian, from the humblest workman upwards, is proud of the architectural splendours of his city, and is willing to make any sacrifice to preserve and enhance them. He is quite insensitive to the fact that from the hygienic point of view his beloved city is a veritable whited sepulchre. London, on the other hand, is magnificent or beautiful only by accident. From the artistic point of view it is marred throughout by the hand of the Philistine. From the point of view of health it is immeasurably superior to Paris. London has an incomparably superior sewage system, and a water supply ample for its vast population and virtually of complete purity. The water supply of Paris is lamentably deficient and even far from safe from pollution. Paris more than any other similar city, sets the example to the whole country of which it is the capital, and the description which you give of French hygiene throughout errs only by its extreme moderation. The sanitary conditon of many French towns is at least in some respects, worse than mediæval. In the olden days the latrines and privies lay outside the houses. Now they are placed inside, and the whole apparatus serves to carry into and diffuse through the houses new and old fœtid gases given off in the closets and generated in the cesspools and sewers with which they are connected. It would be a nice question to discuss whether an acute artistic sensibility or a keen appreciation of cleanliness and health denotes the higher civilisation, but there cannot be any doubt that in the loftier or lower senses of the word it would pay France to raise herself in this matter of public hygiene at least to the level of her neighbours.

I am, Sir, yours truly,
ANGLO-FRANCAIS.

THE MEDICAL PROFESSION AND TRADES UNIONS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The letter from a "Member of the B.M.A." in your issue of September 3rd appears to be written under a slight misapprehension of the actual state of matters. He assumes that the question of recasting the British Medical Association on trades union lines has been thrown out by the vote of the Representative Meeting at Brighton. This inaccuracy mars the effect of an otherwise clear and valuable communication. The truth of the matter, of course, is that the veto of the Representatives is inoperative without the express sanction of the members, in whom is vested the right of final decision. Were this not the case, members would find themselves in the intolerable position of having their subscription raised from twenty-five shillings to two pounds per annum, in accordance with *another* decision of the Representatives at Brighton.

As to the spirit of trades unionism, it is already ingrained in the constitution of the Association. As pointed out in your excellent leader a few weeks since, it is futile to swallow the principle and to shrink from the title. After a somewhat prolonged experience of the medical world I must, for my own part, bewail the absence of so fine a piece of protective machinery as that which characterises the average trades union. Why should not the rate of fees be settled by a central body? Why should it be open to men careless of the honour of their fellows to take threepence or sixpence for medicine and advice? Why should not the position and the privileges of specialists and of consultants be clearly defined? Why should one man be permitted to advertise his name boldly by writing to the leading daily newspapers upon medical subjects while an obscure private practitioner is faced with all the terrors of the General Medical Council if he stray ever so slightly in a similar direction? The cardinal attractions of trades unionism to me are (1) the absolute impartiality of the adopted laws, (2) the framing of those laws by the consensus of opinion of the majority, (3) the advancement of common interests on sound, sensible, commonsense and intelligible grounds.

Much more could be written on this theme, and I trust that some more of your readers will give us their views. Many medical men are inclined to read and to listen rather than to write and to speak—a fact that lessens our chances of self-development to no small extent. May we hope for the emergence of some "mute, inglorious Milton" as the leader of the future medical revolt—whether or not that may have the name of trades unionism inscribed on its banners?

I am, Sir, yours truly,
ANOTHER MEMBER B.M.A.

South London.
September 6th, 1913.

OBITUARY.

MR. ANDREW CLARK, OF UXBRIDGE.

WE regret to record the death of Mr. Andrew Clark, D.Sc. (Hon.) Oxon., F.R.C.S., Honorary Surgeon to the King, which took place on the 29th ult. at Folkestone, at the age of 66. The deceased, who lived at Cowley Grove, Uxbridge, was the son of Benjamin Clark, F.R.C.S. He was educated privately and at University College, London, becoming L.S.A. in 1868, and F.R.C.S. in 1873. After holding the post of Obstetric Assistant at University College Hospital, he became attached to the Middlesex Hospital as Surgical Registrar, Lecturer on Surgery, and Tutor in the Medical School. He was Consulting Surgeon to the Hospital, as well as to the St. Marylebone General Dispensary and the Eastbourne Convalescent Hospital at the time of his death. Mr. Clark was a Colonel in the Army Medical Service (Territorial Forces), and a Knight of Grace of the Order of St. John of Jerusalem. He was a Vice-President of the British Medical Association, of which he was the recipient of the gold medal awarded for distinguished merit in 1905. He had also served as Chairman of the Council and President of the Metropolitan Counties Branch. Mr. Clark was the author of the Middlesex Hospital Surgical Reports, 1872-4, and of "Ambulance Lectures," which appeared in 1888, and edited the fourth edition of "Fairlie Clark's Manual of Surgery."

REVIEWS OF BOOKS.

GLYCOSURIA. (*a*)

We have read this book with great interest. Although some 460 pages are devoted to one disease, or disease group, there is no "padding," and every sentence is of value. The book opens with a description of the carbohydrates, their detection, differentiation, and quantitative determination. In addition, we are informed regarding estimations of total nitrogen, ammonia nitrogen, and other procedures which may be necessary in the full elucidation of a case.

The various forms of glycosuria, experimental, transitory, alimentary, intermittent and persistent, are next dealt with. There is a full account of the symptoms, prognosis and treatment of the latter. There are tables of dietaries with their equivalents in carbon, nitrogen and energy values. These should be of great service since, as the author very properly remarks, to give a patient a list of what to eat and what to avoid is really to do very little for him. The closing section deals with the less common carbohydrates which may occur in the urine, and there is an appendix on the chemical properties and reactions of carbohydrates and related substances. It is all well done. The book makes it abundantly evident that the treatment of a diabetic patient is not to be lightly undertaken, but a study of its pages will be a great help in dealing with a case. We cannot recall a book with a larger number of mercilessly split infinitives.

OBSTETRICS. (*b*)

This is a fine example of the modern text-book—a good style, beautiful and abundant illustrations, and well bound. The author is not an extremist, and his opinions are tempered with much common sense. He advocates as few vaginal examinations as possible during labour. The perineum is best protected not by pressure on it, but by keeping the head well flexed. Unlike Hirst, he advocates immediate suture of all lacerations. Eclampsia is well discussed, but very little space is given to the conservative methods which have proved so valuable at the Rotunda and elsewhere.

We are glad to see that Dr. De Lee emphasises the fact that in placenta prævia the cervix is very sodden, and therefore the risks of tearing it are very real when rapid dilatation or delivery is performed. The chapters on contracted pelvis are very good, but Skutsch's pelvimeter hardly warrants dismissal in a couple of words. For its purpose it is the most accurate instrument we possess. The author advocates, in all but extreme degrees of contraction, a watchful expectancy, forceps being used if necessary. Pubiotomy is to be employed in selected cases, but on the whole Dr. De Lee is not enamoured of it. He uses forceps for the after-coming head in breech cases.

We are glad to see that the bougie method of inducing labour does not get unqualified approval. At the best it is unsatisfactory. He discusses puerperal sepsis in very conservative fashion. Routine douching and the use of the curette are condemned. This section was apparently written before the latest British papers were published on the use of vaccines, and this method of treatment is not adequately treated. One would have expected more in a book of the size on a topic of increasing interest such as the operative treatment of puerperal sepsis, especially ligature of the thrombosed veins.

Thorough exploration of the breast through one incision is recommended for mastitis, and this is really the only treatment worth considering after pus formation.

It is surprising how little known is such a useful instrument as Carton's mucus extractor. It is far superior to any of the tracheal catheters which usually figure in text-books.

These minor criticisms do not detract from our admiration of this monumental work. It represents the best American teaching, and it must be for some time the last word in obstetrical literature. There is a wealth of detail in the description of operative procedures which is usually omitted from such books. The author makes full use of illustrations, which are of a high degree of excellence.

SEA-WATER INJECTIONS. (*a*)

This is the title of a book published by the Scientific Press, and is the work of Drs. A. G. Sandberg and D. M. Tudor, and is intended as a primer for practitioners desirous of learning about sea-water injections, and will be found of special advantage to those who are too far removed from centres where other tuition may be obtained. The number of conditions that seem to be amenable to this kind of treatment appear to be numerous and various, and are not limited, as the prevailing idea of the majority of medical men implies, to that of infantile diarrhœa. Amongst the various chronic diseases which have apparently yielded to its sway are psoriasis, eczema, acne, marasmus, lupus, etc. The small book deals with the collection and preparation of sea water, following which is a detailed account of the *technique* of it manipulation in the applied cases. The records of cases seem to prove conclusively its general utility, and the authors' advice is that the medical practitioner should by preference gain a practical knowledge of the method at the Quinton Polyclinic, London, or visit the Dispensaries Marins in Paris. The volume should prove of immense service as a practical guide to this comparatively new system of treatment.

PERICARDIAL EFFUSION. (*b*)

The treatment of pericardial effusion must ever remain a subject of urgent practical importance. In cases of large collections of fluid suddenly collecting, as sometimes occurs, there must inevitably be extreme danger of fatal syncope. And as the fluid collects—in obedience to the simple law of gravitation—from below upward, while the tense pericardial sac is very easily reached through the epigastrium, the practical inference is obvious. Very thin tendinous strips ("anterior crura") connect the diaphragm with bone at the xipho-sternal junction; and there is even a "cellular" interval on either side of the same between it and the adjacent attachment of the phrenic fibres to the circumference of the costal arch. Thus the distended pericardium is much more easily reached here than anywhere else, as every skilled anatomist knows. The present writer's practical standpoint is: "Nous estimons qu'il est du devoir du praticien d'intervenir *toujours et sans délai* dans toutes les péricardites avec épanchement." There can be no question as to the critical position of the patient who has to oppose his vital powers to the mechanical drag imposed by a considerable pericardial effusion, and the ever imminent danger of syncope. It is of interest that the procedure of *péricardotomie sous-cost-épigastrique* was first described in 1798 by Larrey, the deservedly celebrated surgeon

whom Napoleon referred to in his last will and testament as the best man he ever knew. The fact, too, that a famous Irish scientist of the past generation (Dr. Samuel Haughton, F.T.C.D., F.R.S.) promulgated the thesis that the premature death on the cross was due to such pericardial syncope, as evidenced by the "blood and water" which escaped through the spear-wound may here interest explorers in the byways of knowledge.

GYNÆCOLOGY. (*a*)

THE popularity which has been accorded this work is well deserved, and this edition, which is the fifth since 1905, like its predecessors will enjoy marked favour. In it is found what one might call a treatise on the most healthful costumes which a woman should wear and on the most suitable gymnastic exercises in which a woman should indulge, in order to remain healthy: this treatise might with advantage be issued in pamphlet form for the benefit of laywomen.

From a student's point of view the descriptions of the normal position of the uterus, and the definitions of version and flexion are too complicated, and we cannot urge too strongly the adoption of a standard for these over-discussed matters. The author advises ventral fixation or supravaginal hysterectomy with fixation of the cervical stump as the operative treatments for prolapse of the uterus. He prefers mechanical means of support for those still in the child-bearing period, and wisely points out that these latter women must be rendered sterile when ventral fixation is performed. We marvel that he deems such well-known operations as shortening of the utero-sacral ligaments, and interposition of the uterus, unworthy of notice. Baldy's operation is the one of choice for backward displacements.

All observant gynæcologists will welcome Dr. Ashton's opening sentence in the discussion of the "Treatment of Myomata":—"I am of the opinion that the majority of uterine fibromata demand removal." All the various treatments of uterine fibroids are discussed, and those who have seen malignant degeneration follow palliative treatment will feel pleased with the dictum: "The X-rays should not be employed in the treatment of uterine fibroids except when an operation is contraindicated, either on account of the physical condition of the patient or her refusal to submit to radical measures." Dr. Ashton is convinced of the danger of cancer following laceration of the cervix, and recommends examination and suture if necessary within three or four months of labour as a palliative measure. He adopts the abdominal route when the disease is present, but he considers that "it is only in the early stages when the disease is limited to the uterus that hysterectomy is indicated, and if the vagina, the rectum, the bladder, the broad ligaments, or the cellular tissue of the pelvis is involved, a radical operation is useless." In our opinion it is fortunate that there are many who will operate even at such a late stage.

All the text is most systematically tabulated and makes easy reading. The volume, which is large, well bound, and profusely illustrated, will be found most useful as a reference book on any subject of gynæcological interest to the specialist, the general practitioner and the student.

THE MODERN HOSPITAL. (*b*)

THIS volume is an excellent illustration of the American genius for skimming the cream of the results of scientific research and utilising the same in the improvement of the naturally somewhat bitter beverage supplied to humanity in the cup of daily life. The authors disarm the reviewer of his critical asperity by announcing their "appreciation of its many shortcomings and of its unfinished character." But we can encourage them by stating our own with corresponding promptitude. The examination of the architecture, ventilation, drainage, and furniture of the twentieth-century hospital is carried out with a thoroughness and perspicacity which are thoroughly worthy of the highest ideals of the healing art. The authors indicate that their "book has the tremendous weakness of being a record almost wholly of the experiences of two men," which would, at first sight, imply a supererogatory display of modesty. But they hasten to add the following philosophic reflection, which we cordially appreciate: "In justification, it may be urged that the history of mankind is a composite of individual life stories, and it is only an infinitesimal number of these millions of members of human society who have here ventured to record their own experiences, not in the hope of permanent fame or glory, but merely with the hope that there may be contained within its pages some new thought, or some old thought clothed in new garb, that may help some perplexed and tired worker; and if this shall come to pass the book will not have been written in vain." We have pleasure in ranging ourselves on the side represented by this expression of view-point, and gladly embrace the opportunity of pointing out that the present structure of the whole healing art, as adaptable to immediate human needs, is not "a composite of individual" experiences and the opinions based thereon; and that the present unsatisfactory state and rate of clinical practice and progress are largely due to the persistent ignoring of that very fact which has so adhesively accompanied the rapid advances of materialistic speculation and mechanical discovery and invention throughout their grossly illogical generations.

The mention of "articles made by individuals and firms, and the names and addresses" is, of course, more Chicago-like than we are accustomed to in the British Isles; and the authors take care to announce in the preface that "not one single dollar has been paid by anyone," while the reader has "an unquestionable right to all the information at the authors' disposal." We have perused this largely comprehensive volume with both profit and pleasure, and cordially recommend it to the attention of all specially interested in hospitals.

SURGERY OF THE STOMACH. (*a*)

THIS is a well-written volume on a subject which is unquestionably very prominent "in the public eye" of the present generation—even of the lay section, as well as of the surgical. The facts which our author emphasises are that "The stomach is affected with cancer more frequently than any other organ of the body, and yet partial gastrectomy is one of the uncommon operations of surgery." Indisputably true, then, is the reflection: "The saddest and most discouraging part of the work of a surgeon is the frequency with which he sees patients suffering from cancer so advanced that the time for a radical operation has gone for ever. Especially is this true of gastric cancer. In less than five per cent. of the cases I see is a radical operation possible." Every practitioner of experience knows that this appalling picture represents all too accurately the dismal facts in question; and this state of things, which should not exist, must, we should say, surely come to an early termination in the present state of surgical science and of popular intelligence.

On the rather curious and still decidedly obscure clinical entity of duodenal ulcer the author is very interesting, even if not always satisfactorily illuminating. One of the curious cases of his own experience was that of a lady who suffered severe recurrent attacks of hæmatemesis and melæna. On opening the abdomen he "found an enormously large appendix measuring $3\frac{1}{2}$ inches in diameter, and containing three large foul-smelling concretions." (!)

(*a*) "A Text Book on the Practice of Gynæcology for Practitioners and Students. By Easterly Ashton, M.D., LL.D. Fifth Ed. Pp. 1,100. Philadelphia: W. B. Saunders Co. 1912. Price 27s. 6d. net.

(*b*) The Modern Hospital, its Inspiration, its Architecture, its Equipment, its Operation." By John Allan Hornsby, M.D., and Richard E. Schmidt, Architect, Fellow American Institute of Architects. With 207 illustrations. Philadelphia: W. B. Saunders Company. 1913.

(*a*) "The Surgery of the Stomach: A Handbook of Diagnosis and Treatment." By Herbert J. Paterson, M.A., M.C., M.B. Cantab., F.R.C.S. With plates. London: James Nisbet and Co., Ltd. 1913.

A year later he re-opened the abdomen on account of the recurrrence of the symptoms mentioned, "and on this occasion found a well-marked indurated duodenal ulcer adherent to the liver." He concludes that "a superficial ulcer, which could not be felt, existed at the time of the first operation." Such cases are pre-eminently worthy of special record, as they tend, by their collective statistics, to prepare the surgeon for the unexpected, and even the startling, on laying open the abdominal cavity—even when the prevalent symptoms were of the very ordinary and commonplace.

OPHTHALMOLOGY. (*a*)

In this volume diseases of the eyelids are first considered, and many of the commoner affections here discussed are of much interest to the general practitioner who may be called on to treat them. The next section deals with injuries of the eyes, in the course of which the subject of sympathetic ophthalmia comes under review. We are much surprised to find no mention is made of the value of large doses of sodium salicylate in the treatment of this grave condition. Fortunately, the translator has somewhat remedied this omission by including a footnote in which he mentions this fact. Under this section also there are included several paragraphs in which the medico-legal aspects of eye injuries are discussed. But perhaps the most important eye condition dealt with in this volume is glaucoma, just over sixty pages being devoted to this subject. In view of the full manner in which the matter has been treated, it is amazing that nothing is said about the newer sclerectomy operations recently advocated. It is a pity the translator has not seen fit to introduce some remarks on the matter. Among the other conditions reviewed are diseases of the vitreous, sclera, lachrymal organs, and orbit. The concluding chapter on muscular or concomitant strabismus is excellent, and we can heartily support the author's earnest plea for the early treatment of strabismus. We also note with pleasure that he does not advocate operation without giving a prolonged trial to more conservative measures.

The most serious faults of this work seem to lie in errors of omission rather than in those of commission, and in the failure of the author to recognise that advances in ophthalmology may originate in countries other than his own. We cannot congratulate the author on the illustrations, several of which might with advantage have been left out. The translator has carried out his work well, and it is difficult to realise that the book is not in the original.

LEWIS ON CLINICAL ELECTRO-CARDIOGRAPHY. (*b*)

The author offers to the medical profession an account of clinical electro-cardiography "with the conviction that this new method of examination has become essential to the modern diagnosis and treatment of cardiac patients." We are already familiar with Dr. Thomas Lewis's convictions, but until a concise manual appears in language which is intelligible to the average medical reader who is unacquainted with the detailed procedure of this special method, we feel that it will not assume the popularity which it should. The present work forms an excellent manual of directions for the physician who contemplates setting up an electro-cardiographic station, or for a medical man recently placed in charge of an electro-cardiographic department. To the average practitioner, however, its utility is not as obvious, and we think that the author in various places is inclined to be too dogmatic in his interpretation of phenomena which are as yet *sub judice*. We have nothing but praise, however, for the beautiful electro-cardiograms with which the book is copiously illustrated, and we congratulate the publishers on the careful and clear manner in which the illustrations have been reproduced. The first chapter is devoted to details concerning the connection of the patient with the string galvanometer, and the method of obtaining and of checking the accuracy of standardised curves. Chapter II. deals with physiological auricular and ventricular "complexes." The rest of the book has to do with anomalies in the form of the electro-cardiogram and with the main types of disordered heart action, in which it is now universally acknowledged that electro-cardiography gives indications unattainable in many cases by the use of other methods. Such conditions are auricular-ventricular heart-block, premature contractions, simple paroxysmal tachycardia, auricular "flutter" and fibrillation, and disturbances due to variation in rate of impulse formation at the physiological pace-maker—*e.g.*, respiratory arrhythmia and the like. The relationship of cardiography to various of the valvular diseases of the heart receives brief notice in the final chapter.

A STITCH IN TIME. (*a*)

In this small volume will be found, carefully indexed, a large number of minor casualties which are apt to occur in domestic life, with the appropriate first-aid treatment for each simply and concisely described. As far as possible technical terms are avoided, and the remedies suggested are those which are generally found in every household. The directions given should be readily understood by persons with no medical knowledge, and, as a rule, they are safe. We would suggest, however, that a caution regarding the inflammability of kerosine oil, recommended as an application for "lice," be added in a future edition to the directions for dealing with that affection. The book is a reliable guide to the first-aid treatment of minor and trivial ailments, and it is worthy of a place in every home.

MEDICAL TECHNIQUE. (*b*)

We do not know any other work of precisely the same scope as this of Dr. Albert Morrow's. Omitting all reference to surgical operations, he gives a description of the various technical procedures required in diagnosis and treatment. The book is, therefore, not a handbook of diagnosis, nor yet of treatment, nor is it concerned with the technique of the laboratory any more than with that of the operating theatre. The best idea of its intention can, perhaps, be given, by selecting at random a few items from the table of contents. Thus, under the heading of "Exploratory Punctures" (Chapter ix.), we find references to—exploratory punctures in general, and, in particular, of the pleura, the lung, the pericardium, the peritoneal cavity, the liver, the spleen, the kidneys, the joints, and the spinal canal. Again, Chapter xv., on The Stomach, has the following sub-headings:—Anatomic considerations, diagnostic methods, inspection, palpation, percussion, auscultation, inflation, extraction of contents, test of motor function, test of absorption power, gastrodiaphany, gastroscopy, skiagraphy, exploratory laparotomy, therapeutic measures, lavage, the stomach douche, gavage, massage, electrotherapy. In the chapters dealing with other matters the treatment is as full.

It will be seen that a book of the scope of Dr. Morrow's has the possibility of much usefulness. Success will depend on his manner of treating his subject. It is sufficient to say that the descriptions of the various procedures, though necessarily brief, are lucid and orderly, and, as far as may be, complete. Some space might, it is true, have been saved for more useful purposes by omitting the 65 pages dealing with the administration of general anæsthetics. It is impossible to treat such a subject satisfactorily

(*b*) "Diagnostic and Therapeutic Technic, a Manual of Practical Procedures Employed in Diagnosis and Treatment." By Albert S. Morrow, A.B., M.D. Pp. 775, illustrated Philadelphia: W. B. Saunders Co.

in a single chapter of a work of this kind. On the other hand, the chapter dealing with the collection of pathological material ought to be of service to the general practitioner, to whom such duty frequently falls. At present he too often spoils much good material, and defeats his own ends by his ignorance of technique. Dr. Morrow's directions how to obtain material from the uterus are not satisfactory. He warns against inserting a pipette past the cervix, forgetful of the fact that the contents of the cervical canal may differ widely from those of the uterus. His illustrations, too, of vaginal and rectal examinations are open to the criticism that the operator is depicted without gloves.

The book, on the whole, is one of the most useful we have recently met, and we can warmly recommend it to the physician and the general practitioner.

CONSUMPTION. (a)

The bibliophile of a hundred years hence will, we fear, be not a little embarrassed when he comes to deal with the works on tuberculosis published in the early part of the twentieth century. Should such a one be tempted to make a collection of books on that subject he would find his shelves crowded beyond endurance, and if he unwisely attempted to read them, in order to make a selection of what was most deserving of preservation, he would be bewildered by the multiplication of words and disappointed at the paucity of ideas. Reiteration, however, is one of the effective instruments in the hands of the teacher, and we presume that, till the public have learned their lesson and taken the necessary steps to stamp out tuberculosis, the teachers must continue to reiterate their warnings and instructions. We trust the lesson will soon be learned. While speaking thus of the subject we have no desire to belittle the treatment of it by Dr. Thompson, who has given us quite a good summary of our knowledge, and one which will no doubt serve its purpose of assisting the general practitioner to do his share of the work of stamping out the disease. If there is not much new knowledge in the book, it is because there is not much that is new to put in it, and at all events the old is dressed in an attractive form. We have some doubt as to the wisdom of advising the general practitioner to prepare his own dilutions of tuberculin. In this matter accuracy is of great importance, and accuracy is not readily attained in such matters without considerable practice. It is questionable too if there is any great saving of expense, as the dilutions are apt not to keep well.

LITERARY NOTES.

A useful little book for students of first aid is "A Compendium of Aids to First Aid" (Bale, Sons and Danielsson, Ltd.), by Dr. N. Corbet Fletcher. In a preface by Dr. James Cantlie it is stated that this pocket guide is not intended to supplant the study of text-books, but to concentrate the knowledge thereby gained for practical application in times of emergency. With this special end in view, Dr. Fletcher has adopted a most ingenious system of "tips," which head the various sections. Thus "clip" is the tip for remembering the different varieties of wounds—contused, lacerated, incised, punctured; while "Broad Street Special" is designed to assist the memory in the treatment of insensibility. Those who believe in the virtues of mnemonics will do well to obtain this excellent little handbook, which will be a godsend to many lecturers and candidates in first aid.

* * *

Those of our readers who are familiar with the German language and who wish to keep themselves informed of the latest ideas with regard to the pathology and treatment of internal medical disorders, cannot do better than study the ten volumes of "Spezielle Pathologie und Therapie innerer Krankheiten," published by Hrn. Urban and Schwarzenberg (Berlin and Vienna), three numbers of which we have received. The editors are Prof. Dr. Friedrich Kraus and Prof. Dr. Theodor Brugsch, of Berlin, assisted by one hundred of the most eminent specialists. Each issue contains several selected articles, in monograph fashion, by experts, but these are not so unwieldy as the classic encyclopædias of Nothnagel and Ziemssen. Special prominence is given to clinical observation and treatment, and copious bibliographies appear after each article. There are numerous coloured plates and photographic illustrations. The price of each number is 2 marks.

* * *

The first number of the *British Journal of Surgery*, recently issued, is an imposing quarterly symposium embodying all that is best in British surgical art and science. A good photograph of Lord Lister very aptly forms the frontispiece, while among the distinguished contributors are Messrs. Albert Carless, D'Arcy Power, David Newman, Sampson Handley, G. E. Gask, H. Morriston Davies, Robert Jones, and S. Alwyn Smith. In a foreword Sir Rickman J. Godlee expresses the opinion that the new journal will prove a medium through which British surgeons can make themselves intelligibly heard. That it will rank side by side with the great foreign annals and archives of surgery is evident after a perusal of the first number. Sir Berkeley G. A. Moynihan is the chairman of the Editorial Committee, and Mr. E. W. Hey Groves (Bristol) is the Editorial Secretary. The publishers, Messrs. John Wright and Sons, Ltd., Bristol, are to be congratulated upon the excellence of the type and the illustrations. Single numbers are 7s. 6d. net, and the subscription price is 25s. net per annum. We heartily wish the journal all the success it deserves.

NEW PREPARATIONS.

From Messrs. Reitmeyer and Co., 63 Crutched Friars, E.C., we have received a pentad of interesting and valuable preparations, manufactured by Dr. Walter Wolff and Co., Elberfeld. Of these

METAFERRIN

is an organic preparation containing 10 per cent. each of iron and phosphoric acid, fixed in digested milk albumen, put up in 4-grain tablets, which are rapidly soluble in water. Metaferrin may be given in all cases where a course of iron is indicated.

ARSENO-METAFERRIN

is not a mixture of arsenic and metaferrin, but a derivative of the latter containing 0.1 per cent. of arsenic in organic combination. Neither of the two chief ingredients are separated by the gastric juice, hence arseno-metaferrin is well tolerated. This preparation will be found useful in anæmic conditions and also in obstinate skin cases.

IODO-METAFERRIN

consists of 7.5 per cent. of iodine in organic combination, an equal proportion of iron, and 8 per cent. of phosphoric acid. Experimental research has demonstrated the superiority of iodo-metaferrin over iodo-iron preparations as regards slow and uniform excretion, and it has also the advantage of being well tolerated, permanently stable, tasteless, and stimulates the appetite.

ROMAUXAN

is a nutritive preparation containing iron, phosphorus, and a high percentage of digested milk albumen. It has the advantage of not upsetting the digestion, and it dissolves readily in the intestine. As a body builder in debilitated states it may be taken in teaspoonful doses three times daily. One ounce of this excellent food costs tenpence.

TRICALCOL

is tricalcium phosphate, combined with milk albumen, in which the phosphate exists as a colloid in the proportion of 20 per cent. Its lime is more readily absorbed in the intestines than the lime of cow's milk, and in view of the fact that lime-salts have been recommended as a prophylactic against tuberculosis, tricalcol would seem to be an ideal preparation to administer in anæmic states and also in pregnancy, as well as in rickets. A one-ounce packet costs 1s. 3d.

(a) "Consumption in General Practice." By G. Hyslop Thompson, M.D., D.P.H., Medical Superintendent, Liverpool Sanatorium. 8vo., pp. xvi. and 335. London: Henry Frowde and Hodder and Stoughton. 1912.

MEDICAL NEWS IN BRIEF.

Opening of the Medical Schools.

Charing Cross Hospital.—Lady Wantage will distribute the prizes in the Out-patients' Hall of the Hospital on Wednesday, October 1st, at 3.30 p.m.

St. George's Hospital.—Sir William Osler, Bart., F.R.S., Regius Professor of Medicine in the University of Oxford, will distribute the prizes and deliver the opening address on October 1st, at 3 p.m.

St. Bartholomew's Hospital.—The annual Old Students' Dinner will be held in the great hall of the Hospital on October 1st, at 6.30 for 7 p.m., Dr. Howard H. Tooth, C.M.G., in the chair.

St. Thomas's Hospital.—The annual Old Stulents' Dinner will be held at the Hotel Cecil on October 1st at 7 for 7.30 p.m., Dr. H. P. Hawkins presiding.

St. Mary's Hospital.—Sir John Prescott Hewett, K.C.S.I., will distribute the prizes and awards for 1912-13, and deliver an address on October 1st, at 3.30 p.m. On October 7th the annual dinner of past and present students will be held at Prince's Restaurant, at 7 p.m.

Middlesex Hospital.—The introductory address will be delivered by Mr. W. Sampson Handley, M.S., after which the prizes will be distributed by Sir Squire Bancroft. The annual dinner will be held at 7 p.m. on the same evening at the Trocadero, when Sir James Kingston Fowler, K.C.V.O., will preside.

Westminster Hospital.—The annual dinner will be held on Thursday, October 2nd, at the Imperial Restaurant, Regent Street, W.

London School of Medicine for Women.—Surgeon-General Sir Charles Pardey Lukis, K.C.S.I., will deliver the inaugural address on October 1st, at four o'clock.

University of Birmingham.—The winter session will commence on Tuesday, October 7th, when a reception will be held in the Medical Faculty Buildings, and a lecture delivered by Professor Arthur Keith, LL.D., F.R.S., on "The Present Problems Relating to the Antiquity of Man." A reception will be held at 7.30 p.m., half an hour before the lecture.

An Unqualified Practitioner Fined.

Horatio Franklyn Sparling, optician, of 30 Northcote Road, West Croydon, was summoned at Croydon Police Court on Monday last for unlawfully and falsely using the title of "doctor," thereby implying that he was a registered medical practitioner. He pleaded guilty.

Mr. W. E. Hempson, who prosecuted for the Medical Defence Union, said that the defendant's house in every respect bore the signs commonly associated with the residences of medical men. There was the usual red lamp with the word "Surgery" on two sides of it. The same word was upon the window with the hours of attendance. Beside the door there was a brass plate with the inscription "Dr. H. F. Sparling," but the "Dr." was erased after an inquest held upon a baby recently treated by the defendant. The evidence at that inquiry, when the defendant made certain admissions, was the basis of the present case. The father of the child thought he was dealing with a properly qualified medical man, and obtained a prescription from the defendant. The child died, but there was not the slightest imputation that the medicine prescribed was improper for such a case or contributed to its death. The defendant had had a warning, for in the case of another infant he treated the father was so incensed at what he regarded as the defendant's deception that he placed an abusive notice in his window. Yet he continued exactly as before, and he (the solicitor) submitted that it was a case of absolutely brazen impudence, a degradation to the profession, and a danger to the public.

Mr. Wilberforce Jackson, on behalf of the defendant, said that the defendant had had experience as a dispenser. For some time he acted as a dispenser and general assistant to a doctor in New Zealand. He returned with a knowledge of drugs and simple anatomy. He was anxious to qualify but had not the means. He entered into a sort of partnership with a qualified man—verbal, without a deed. The defendant was quite under the impression that he could call himself a doctor if he did not use the words "physician" or "surgeon." His "partner" did not tell him he had no right to do that. The defendant had refused all serious cases that came his way.

The defendant was fined five guineas, with £4 14s. 6d. costs.

Artificial Sunlight for Cripples.

Sun treatment has proved so beneficial to the little sufferers from tuberculous bone and joint disease at the Cripples' Hospital at Alton, Hampshire, that an apparatus for making artificial sunlight is to be obtained. Mrs. Lindsay Johnston has presented a sum of money for the apparatus, and Sir William Treloar and Dr. Gauvain, the Medical Superintendent, will shortly visit Germany to study the latest developments of the ultra-violet rays treatment.

Throat Hospital Jubilee.

Mr. A. W. Mackenzie, a trustee of the Throat Hospital, Golden Square, and the only survivor of those who, fifty years ago, assisted his brother, Sir Morell Mackenzie, in founding it, has issued an appeal for subscriptions to the jubilee fund of £12,000. As necessity and opportunity have arisen the hospital has been rebuilt and extended, and lately the property of No. 33 Golden Square, was bought. The fund is needed to pay the debt on this latest addition. Subscriptions and donations can be sent to the Treasurer, Mr. G. H. Pember, or paid into the Jubilee Fund account at Sir Samuel Scott and Co. (Parr's Bank), Cavendish Square.

Cremation in the United Kingdom.

It is reported that last year's cremations in the United Kingdom numbered 1,064—the largest number recorded since cremation was first practised in this country in 1885. Of these 15 were at Woking, 149 in Manchester, 44 in Glasgow, 52 in Liverpool, 27 at Hull, 15 at Darlington, 14 at Leicester, 521 at Golders Green, 40 in Birmingham, 24 at Leeds, 32 at Ilford, 12 at Sheffield, and 9 at Bradford. Since 1885 the total number of cremations has been 11,047—namely, at Woking, 3,565; Golders Green, 3,480; Manchester, 1,733; Liverpool, 603; Glasgow, 435; Birmingham, 270; Hull, 254; Ilford, 107; Leeds, 143; Leicester, 131; Sheffield, 91; Bradford, 82; and Darlington, 87. The first crematorium in England was opened in 1885 at Woking, when three bodies were cremated. Several large cities afterwards at intervals established crematoria, and the Golders Green Crematorium was opened in 1902. The City of London Crematorium at Ilford was established in 1905.

NOTICES TO CORRESPONDENTS, &c.

☛ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Reprints.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

NOTICE TO HOSPITAL SECRETARIES AND COLLEGE DEANS.

THE Editor wishes to thank the above gentlemen attached to the various Schools and Hospitals for supplying him with the information from which the foregoing pages have been composed.

NOTICE TO OUR READERS.

As this number is mainly devoted to information necesary for students intending to join one or other of the verious medical colleges and for those who, having passed their curriculum, are about to enter the ranks of the profession, much of the ordinary matter which usually fills our columns is necessarily deferred till next week.

GRATUITOUS COPIES.

A VERY large number of copies of this issue are being sent gratuitously to all the educational establishments, hospitals, reading-rooms, clubs, and large hotels in the United Kingdom, and to a large number in America, India, the Colonies, and on the Continent; should any of our readers desire to present a copy to a patient or friend who contemplates sending his son to a medical school, our publisher will be happy to supply him with a duplicate free of cost on receipt of address.

Dr. P. T. (London, W.).—Thallium acetate may be used with safety for the removal of downy hairs upon the lips, which are unsuitable for electrolysis. Sabouraud gives the following formula:— R Thallium acetate 0.30 gram, zinc oxide, 2 grm., vaseline 20 grm., lanolin 5 grm., rose-water, 5 grm. The action of this salve is slow and progressive.

THE M.D. BRUSSELS.

THERE are three examinations for the M.D. degree of the University of Brussels which must be passed in due order, the whole time taking about ten or tweleve days. The examinations aro conducted in French for the most part, and the fees amount to £22. Many British medical men are holders of this degree. All information may be obtained from Dr. Arthur Haydon, Hon. Sec. of the Brussels Medical Graduates' Association, 23, Henrietta Street, Cavendish Square, W.

Mr. T. Smith (Peckham).—Our correspondent would probably win his case if he can prove that the trap was defective when he took over the premises. The old-fashioned hopper closet pan is now rapidly being displaced by the modern flush-out type.

F.R.C.S.Ed. (Glasgow).—The population of Australia numbers about 6,000,000, according to the most recent returns; that of New South Wales is slightly in excess of Victoria, these being the two predominant states. Queensland, South Australia, West Australia and Tasmania follow in the order given.

THE ROYAL SANITARY INSTITUTE.

AT the Royal Sanitary Institute, the Fifty-sixth Course of Lectures and Demonstrations for Sanitary Officers will commence on September 15th. A Course of Lectures on School Hygiene, for women health visitors and school nurses, will commence on October 6th; a Course of Practical Training for Meat Inspectors will commence on September 26th; a Short Course of Training Lectures on Tuberculosis, suitable to the requirements of women sanitary inspectors and health visitors, and to those whose duties include the visiting of phthisis cases, to be delivered by Dr. J. E. Squire, C.B., at 6 p.m. on Wednesdays during October.

Appointments.

Clarke, Isaac, L.R.C.P. and S.Irel., Medical Officer of Health to the Frocingham Urban District Council.

Finch, G., M.R.C.S., L.R.C.P.Lond., Assistant County Medical Officer of Health for East Suffolk.

Finlay, Douglas Edward, M.B., B.S.Lond., M.R.C.S.Eng., L.R.C.P.Lond. Physician to the Gloucestershire Royal Infirmary and Eye Institution.

Great-Rex, J. B., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory and Workshop Acts for the Kidsgrove District of the County of Stafford.

Gyllencreutz, James Randolph, M.R.C.S., L.R.C.P.Lond., Senior Assistant Medical Officer at St. John's Hill Infirmary, Wandsworth.

Heffernan, John Thomas, L.R.C.P. and S.Irel., Medical Officer to the Carney, Sligo, District.

Herbert, Noel M. G., L.R.C.P. and S.Irel., L.M.Rot., Assistant Medical Officer to Whittingham Asylum, Preston, Lancashire.

Nimbkar, V. D., L.R.C.S. and P.Edin., L.F.P.S.Glasg., House Surgeon to the Stroud General Hospital, Gloucestershire.

Nutt, W. H., M.D., Ch.B.Edin., Honorary Radiographer to the Chesterfield and North Derbyshire Hospital.

Vacancies.

Canterbury Mental Hospital, Canterbury.—Assistant Medical Officer. Salary £200 per annum, with board, lodging, washing, and attendance. Applications to the Medical Superintendent.

Royal Sea Bathing Hospital for Surgical Tuberculosis, Margate. —Resident Surgeon. Salary £120 per annum, with board, residence and laundry. Applications to the Secretary, R.S.B.H. Offices, 13 Charing Cross, London, S.W.

The Queen's Hospital for Children, Hackney Road, Bethnal Green, E.—Medical Officer. Salary £100 per annum. Applications to T. Glenton-Kerr, Secretary.

Carlisle Non-Provident Dispensary.—Resident Medical Officer. Salary £200 per annum, with apartments (not board). Applications to the Hon. Secretary, Mr. G. A. Lightfoot, 23 Castle Street, Carlisle.

St. Mary's Hospital for Women and Children, Plaistow, London, E.—Senior Resident Medical Officer. Salary £100 per annum, with residence, board, and laundry. Applications to the Secretary.

Alnwick Infirmary.—House Surgeon. Salary £140 per annum, with plain board and furnished apartments. Applications to Harold J. Hardy, 32 Bondgate Without, Alnwick.

The Queen's Hospital for Children, Hackney Road, Bethnal Green, E. Resident Medical Officer. Salary £125 per annum, with board, residence, and laundry. Applications to T. Glenton-Kerr, Secretary.

Royal Hospital for Diseases of the Chest, Prevention of Consumption Department, City Road, E.C.—Medical Officer. Salary £250 per annum. Applications to the Secretary.

Oxford County Asylum, Littlemore, near Oxford.—Assistant Medical Officer. Salary £150 per annum, with apartments, board, and washing. Applications to the Medical Superintendent

Certifying Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointments:—Ballindalloch (Banffshire), Barmouth (Merionethshire), Raphoe (Co. Donegal).

Births.

Foster.—On August 31st, at Sussex House, Tilehouse Street, Hitchin, the wife of Arthur H. Foster, M.R.C.S., L.R.C.P., a son.

Hunt.—On August 31st, at Secunderabad, Deccan, India, the wife of Edmund Henderson Hunt, F.R.C.S., a daughter.

Moilliet.—On August 1st, at Aire Libre, Puebla, Mexico, the wife of Alexander Keir Moillet, M.D., a son.

Marriages.

Bailey—Guard.—On September 2nd, at St. Paul's Church, Wooburn, Bucks., George Frederick Selborne Bailey, M.D., of Clayton's, Bourne End, Bucks., son of Mr. and Mrs. G. F. Bailey late of Towalla, Watford, to Mabel Yardley, eldest daughter of Mr. and Mrs. Henry Guard, Harrage, Romsey.

Bankart—Moss-Blundell.—On August 30th, at the Chapel Royal, Savoy, Arthur S. Blundell Bankart, M.C., F.R.C.S., to Beryl Winifred, daughter of A. S. Moss-Blundell, of Winchester.

Early—Banks.—On September 3rd, at the Wesleyan Church, Tottenham, London, Philip Vanner Early M.B., B.S. third son of Mr. and Mrs. James Vanner Early, of Witney, to Margaret Winnifred, elder daughter of Rev. and Mrs. T. Hardy Banks, of Tottenham.

Gaff—Needham.—On September 4th, at St. Margaret's, Westminster, Dr. James Gaff, of Hammersmith, only son of Dr. James D. Gaff, of Ewell, to Nellie, only daughter of Richard Needham, J.P., of Stalybridge.

Lock—Smith.—On September 2nd, 1913, at St. Mary's Church, Wymondham, Norman Francis Lock, M.A., M.B.Cantab., F.R.C.S.Eng., of Boston, Lincs, third son of the Rev. and Mrs. John B. Lock, of Herschel House, Cambridge, to Harriet Mary, eldest daughter of Mr. and Mrs. Wm. Partridge Smith, of Wymondham.

MacDonald—Robinson.—On September 3rd, at the Parish Church, Burgess Hill, Sussex, Peter Hay MacDonald, M.B., Ch.B., younger son of Mr. and Mrs. MacDonald, of Leith, to Ada Theodora, eldest daughter of Mr. and Mrs. Robinson, of Burgess Hill, and late of Upper Tulse Hill, London.

Sandison—Gold.—On September 4th, at South Croydon Congregational Church, Alexander Sandison, M.B., B.C., B.A., B.Sc., to Esther Catherine, eldest daughter of Mr. R. W. Gold, Controlling Officer of H.M. Customs, of Llanberis, Spencer Road, South Croydon.

Saner—Dunster.—On September 4th, at the Parish Church, Hanwell, Middlesex, Francis Donaldson Saner, M.D., youngest son of the late John Saner, Esq., of Hull, to Marjorie, daughter of John Dunster, of Golden Manor, Hanwell.

Stoddart—Norman.—On September 2nd, at St. John's, Angell Town, Brixton, assisted by the Rev. F. Lock, George Stoddart, of 11 Ashbourne Avenue, Golder's Green, to Beatrice Eleanor, eldest daughter of Frederick Norman, J.P., F.R.C.S., of Wiltshire House, Wiltshire Road, Brixton.

Watts—Holloway.—On September 2nd, at the Church of St. Mary the Virgin, Chipping Norton, Oxfordshire, John Ernest Price Watts, F.R.C.S., L.R.C.P., son of H. Ernest Watts, L.R.C.P.Lond., L.R.C.S.I., L.S.A., of Sunnyside House, Belmont Road, Ilford, to Elves Lilian Norfolk Holloway, elder daughter of William T. Holloway, of Fern Villa, Chipping Norton.

Deaths.

Alden.—On the 29th ult., at the Acland Home, Ebenezer Wenham Alden, M.R.C.S., L.S.A., of 37 Beaumont Street, Oxford, aged 63.

Ozanne.—On the 3rd inst., at Sheen House, Harrogate, Fanny Lydia, the beloved wife of Fred. N. Ozanne, L.R.C.P.Lond., M.R.C.S.Eng.

Tayloe.—On September 7th, at 10 Cedars Road, Clapham, Mary, eldest daughter of Edward Tayloe, M.R.C.S., aged 63.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVII. WEDNESDAY, SEPTEMBER 17, 1913. NO. 12.

NOTES AND COMMENTS.

Syphilis and Salvarsan: Historic Discussion.

ONE of the most interesting discussions at the International Congress of Medicine was that which dealt with the treatment of syphilis by salvarsan. It was opened in person by Ehrlich, the discoverer of the great remedy in question. One interesting point brought out by him was the harmlessness of the drug upon internal organs. Guinea-pigs were not killed by daily doses of from 0.02 to 0.05 gram continued for three months. Its non-toxicity in small, long-continued doses was at the same time thus demonstrated. The febrile reaction following injection, concerning which a good deal was formerly heard, he ascribed to (1) errors in the *technique* of administration, (2) to the toxins generated by the destruction of the spirochætes. He further remarked in this connection that salvarsan killed a great number of organisms besides those of syphilis. Recurrence he believed to be the result of insufficient dosage. As regards mortality, he very aptly remarked that chloroform was annually responsible for a much higher percentage of deaths than salvarsan, and he was confident that the proportion might be materially reduced in the latter case by a careful exclusion of renal inadequacy, Addison's disease, status lymphaticus, and other conditions that contra-indicated the use of "606."

Neisser, Wassermann, and Other Authorities.

PROFESSOR NEISSER, who was unable to attend the Congress through illness, sent a communication in which he expressed his belief that salvarsan had a specific action upon the *Spirochæta pallida*, while he denied a neurotropic influence. The specific bactericidal action, in his opinion, was enhanced by the simultaneous injection of grey oil. He went so far as to advocate two complete courses of salvarsan and mercury even in primary cases. One important paper was by Lieut.-Col. Gibbon and Major Harrison. They gave the results of their routine administration of "606" at the Military Hospital, Rochester Row, London. With mercury alone there were 83 per cent. of relapses, as against only 5.1 per cent. since salvarsan had been introduced. The annual saving to the State effected by this new departure they estimated at 70,000 to 80,000 hospital days, an economy equivalent to the cost of keeping a battalion of infantry in hospital for three months. Professor Wassermann made a point of first-class importance by insisting that the cerebro-spinal fluid of every syphilitic should be examined at least once during the first year after infection for the Wassermann reaction. If positive, prolonged and energetic treatment with "606" and mercury were indicated. He maintained that when once syphilis produced clinical symptoms of cerebro-spinal involvment, it could not be eradicated from the system.

An Ancient and Formidable Disease.

DR. H. MACCORMAC gave an account of 500 cases treated at the Seamen's Hospital without a single death. He was of opinion that the occasional severe reactions which followed a second injection were manifestations of the anaphylactic state. (If such were the case, however, one would rather expect fatal results from a second injection.) Possibly, however, the anaphylaxis might be due not to the salvarsan directly, but to secondary anaphylactic substances resulting from its injection. Several other authorities attributed recurrence to inadequate use of the drug. Dr. J. E. R. McDonagh spoke of "spasmodic" injections of salvarsan that were worse than useless. He also alluded to his own important work in the demonstration of the spore-like bodies present in syphilis (later described by Ross and Noguchi). He claimed that "606" had no effect on these bodies, but affected only the gametic elements (spirilla). Other interesting and valuable suggestions and observations were offered. Amongst them was one by Dr. Schreiber (Madgeburg), who pointed out that prostitutes were voluntarily offering themselves for treatment. Dr. Ullmann (Vienna) dwelt on the fact that an anti-salvarsan paper was offered to the Congress. This discussion is likely to be of historic value as regards the ancient and formidable disease with which it dealt.

French Sanitation.

THE paragraph published in these columns lately upon sanitation—or, rather, insanitation—in France, evoked some interesting correspondence. There seems to be a pretty general consensus of opinion as to the defectiveness of drainage systems both inside and outside the dwelling. Closets of an old, bad type are the rule rather than the exception. In hotels—even those that are large and expensive—the closets are of bad type, ill-ventilated, often out of repair, and totally inadequate for the number of persons in the building. A correspondent says that in one hotel there was a single closet to each floor, which contained some fifty bedrooms. Every morning there was a long queue of visitors of both sexes patiently awaiting their turn. The hotel was without baths. From a frankly financial point of view, it would be a good thing were the French to set their hotels in sanitary order forthwith. Even in Paris itself, it is only in the largest and finest *caravanserais* that really efficient modern sanitation is to be found.

Public Memorial to a Medical Practitioner.

THE establishment of a public memorial to a medical practitioner is an event of some significance. For some forty years the late Dr. William Rutherford practised quietly, modestly, and honestly in the town of Ballinasloe. He cared little for fame, and less for money. "His sole idea," said his friend, Dr. Mills, at the unveiling of the memorial a few days ago, "was to apply such abilities as God had given him in ungrudging measure to the alleviation of the sufferings of those seeking his aid." For forty years he did his duty honestly and intelligently to all who came to him, whether he was to receive any preliminary reward for his services or not. He recreated himself in public matters for the good of the town where he lived. When he died two years ago those who knew him, those among whom he had spent his life, his fellow-citizens and neighbours, felt that it was necessary to express in some tangible form their appreciation of a noble and simple life. The drinking-fountain unveiled recently will teach to future generations the honour that is due to "a sincere friend, an eminent physician, a public sprited and upright citizen." Rutherford's medical brethren feel proud of the respect shown to the memory of a colleague whom they too loved and honoured.

LEADING ARTICLES.

FLIES AND INFIRMARIES.

THE value of progressive science to the man in the street clearly depends on the thoroughness or otherwise with which it is reduced to practice. In the United Kingdom it has hitherto proved a sound asset because of the way in which sanitation is expressed in terms of drains, ventilators, disinfection, isolation and the whole wide range of weapons placed by the legislature in the hands of the medical officer of health. Of late years that most indispensable official has had piled upon him duties of a multifarious and oftentimes exacting nature. Indeed, it is hardly too much to say that almost every great advance in medical science is tolerably certain to add to his responsibilities. In many large centres of population it has been found necessary to revise the conditions of the public health department by applying the principle of division of labour, so that the chief officer has the assistance of a bacteriologist, an analyst, a school medical officer, a tuberculosis officer, and so on. It almost looks as if in the near future a subordinate branch of officials would be required for the special purpose of exterminating flies, which modern science has shown to play an important part in the spread of infection. A vigorous campaign against these insects has been carried on in America for some years past, and less actively in the United Kingdom. There is no need to review the evidence which proves that flies are capable of conveying the germs of cholera, enteric fever, erysipelas, in short, of an interminable series of micro-organisms directly and indirectly pathogenic to man. Of all places, then, the wards of a hospital should be carefully protected from flies by such obvious means as screening, the use of insecticides, but above all by the careful and systematic removal of stable and other garbage from the immediate vicinity. It must be confessed that so far few hospitals have recognised the necessity for such a campaign, and even the best appointed modern institutions permit flies to enter and range the building from cellar to attic—including kitchen—without let or hindrance. The whole issue has been publicly raised by a dispute that is now going on between two London boroughs. It seems that at a meeting of the Southwark Board of Guardians a week or so ago, it was stated by Dr. Bruce, the medical superintendent, that there were 28 cases of enteritis in children, and that six deaths had already taken place. He gave it as his firm conviction that the outbreak was due to poisoning from refuse-filled trucks of the Camberwell Borough Council on an adjoining railway siding. One of the guardians observed there were "millions" of flies in the infirmary, and gave a graphic picture of the way in which patients were tormented by them. The imputation as to the deaths has been stoutly denied by the Camberwell Council, and there the matter stands for the present. It seems to be admitted, however, that within some fifty yards of the infirmary a number of railway trucks stand, and that these are habitually filled with filthy refuse. Anyone versed in the knowledge of modern hygiene would at once ascribe the enteritis in the infirmary to the refuse in the trucks, with infection being carried to the patients' food by the agency of flies. Direct proof of the transmission it would be difficult or impossible to obtain. Under the circumstances it is clearly the duty of the Camberwell Council to put an end to a public danger without a moment's loss of time. Flies or no flies, infirmary or no infirmary, enteritis or no enteritis, the retention of filth in open trucks in the centre of a densely crowded district is intolerable. It has been urged that the trucks have been so used and so placed for the last 35 years. In the light of modern sanitary progress it is deplorable to think of the disease and death that must have resulted therefrom. A few months ago it was our duty to criticise the Southwark Council for their antivaccinationist leanings, but in their present fight for the wholesomeness of their infirmary we wish them speedy and complete success. The local authority, it is said, has made various complaints to the Local Government Board. It will be interesting to watch the action of that official body. Will the protests of Southwark be lost in the pigeon-holes of a circumlocution office, or shall we have a strong commonsense handling of a public nuisance and danger? At any rate, the Local Government Board has so far shown no great activity in the affair, for we understand an inspector was sent to view the dust heaps on the 25th of August. Surely four weeks should have afforded sufficient time for arriving at a decision. Possibly the 28 cases of enteritis and the six resulting deaths may induce the Local Government Board to take a somewhat less leisurely view of their responsibilities in the matter.

FOOD POISONING.

Every medical practitioner is familiar with the outbreaks of illness that occur from time to time, usually in the warmer months of the year, soon after partaking of food. Sometimes patients are attacked with startling suddenness—perhaps on returning home after a public dinner—and not infrequently the illness is of great severity, or even fatal. Cases of "ptomaine poisoning," as they are generally called, may lead to litigation, though it is by no means an easy matter to prove that restaurant keepers or provision merchants are to blame in respect of the quality of the food or the methods of its preparation. A comprehensive report on bacterial food poisoning and food infections, by Dr. W. G. Savage, has just been presented to the Local Government Board (New Series, No. 77), containing an excellent summary of our present knowledge of the subject. It is now generally recognised that illness of this nature is really due to bacterial contamination of food by certain pathogenic organisms, which enter the system either living or, after being killed by cooking, exert a baneful influence by reason of their toxins. In the present report 79 outbreaks in Great Britain and Ireland are analysed, in addition to many more from Continental sources. Various special kinds of food poisoning are dealt with in one section, such as that from mussels, cheese, potato, and ice-cream. The incubation period may be said to average from six to twelve hours, and the three symptoms of vomiting, diarrhœa and abdominal pain are met with in practically every outbreak and in the great majority of cases. The case-mortality rate for the British outbreaks, as far as the figures are available, works out as 2.16 per cent. In nearly all these outbreaks the incriminated meat was derived from pigs or cattle, while in the Continental cases the horse was also concerned. It is noteworthy that the sheep is almost completely absent from the list, only one instance being recorded. Meat pies and tinned or made-up meat seem to have been responsible for the greatest number of cases. The Gaertner group of bacilli were isolated or shown to be the cause in 71 per cent. of the investigated outbreaks, while other organisms met with were the *Bacillus coli*, the B. *botulinus*, and *B. proteus*. It is not yet definitely settled whether the effects of putrefaction, using the term in its widest sense, are sufficient to cause disease apart from the products of any single bacillus. Experimental research appears to show that the ordinary methods of heating may be insufficient to destroy the toxins of the Gaertner group of bacilli in the case of tinned meats. Though the same micro-organisms are held to be responsible for the majority of cases of food infection, it is difficult to trace the means by which they obtain access to food. The hypotheses that the bacilli are of human origin, introduced by human carriers, or from the fæcal infection of food, or that the germs are derived from animals themselves suffering from diseases due to the Gaertner group, are each worthy of consideration; but Dr. Savage is of the opinion that the last view is the one which explains all or most of the phenomena due to food poisoning. The preventive measures against these outbreaks consist briefly in a more rigid inspection of meat at the time of slaughter, greater cleanliness in premises where made-up food is prepared, and a greater official cognisance of food-poisoning epidemics.

CURRENT TOPICS.

Sanitation in Panama.

It cannot be denied that one of the greatest triumphs of modern preventive medicine has been the reclamation of malaria-infested territory for human habitation and commerce. Indeed, it is hardly too much to say that, had it not been for medical science, the Panama Canal could hardly have been constructed at all. The June report of the Department of Sanitation of the Isthmian Canal Commission is of peculiar interest to all engaged in fighting malaria. The fact that the malaria sick-rate for the month in the Canal zone was only .40 per cent., as compared with 8 per cent. in 1906, gives point to the statement that "no anti-malaria work . . . . at the relocation camps other than daily destruction of *Anopheles* in houses has been accomplished this year. In previous years, when such auxiliary work was not accomplished, the malaria sick-rate was relatively higher, even though efforts were then made to destroy mosquito larvæ in near-by ponds, streams, etc. For the six months ended June 30th, 1912, 255 cases of malaria were reported from the 'relocation,' while during the corresponding period of 1913, when all work but destroying mosquitoes in houses was omitted, only three cases were reported. This particular phase of anti-malaria work is thought to be of considerable importance, and is being applied at all villages where *Anopheles* are noted." It is somewhat disquieting to learn that new breeding grounds, difficult to deal with, are being created at the Pacific entrance by the hydraulic flooding of large areas. A new danger is foreshadowed by the discovery of *Anopheles tarsimaculata*, a prolific source of malaria transmission, on the Pacific slope, whither it has been carried in goods brought from Colon. It is not understood why this species, in spite of apparently favourable circumstances, has not become as numerous at the Pacific as at the Atlantic terminal. There is no reason to suppose, however, that any diminution in the work of mosquito destruction will be countenanced by the health authorities.

Cocaine Anæsthesia, and Unregistered Practitioners.

The fear of "taking gas" for dental extraction has rendered the use of local injections with cocaine extremely popular with the general public. Unfortunately the man in the street is still unable to discern the registered from the unregistered dental practitioners, and he generally ends by going to the man who advertises most. It has been estimated that about 200,000 injections of anæsthetics are made every day by unqualified men. If this be the case, the risks attendant upon the practice cannot be too widely known. In the interim report of the Committee of the British Association appointed to inquire into deaths by, or during, anæsthesia presented at the Birmingham meeting last week, attention was drawn to three fatalities which had occurred during the past few months among members of the working classes to whom cocaine, or one of its derivatives had been administered for tooth extraction by unregistered dentists. Apart from the numerous cases of poisoning which result from this alkaloid, there is the grave risk of septic infection owing to the introduction of pyogenic organisms through deficient sterilisation of the injecting appliances. Further, there is the laceration and reduction of vitality of the inflamed tissues into which the analgesic solution may have been forced, resulting in sloughing or necrosis. The present report is a strong plea for the endorsement and strengthening of the resolution passed two years ago at Sheffield representing to the Home Office and to the Privy Council the urgent need of legislation to protect the public against unnecessary risks incurred through the administration of anæsthetics by unqualified persons. Sir Frederic Hewitt emphasised last week the strong necessity that further steps should be taken by the Legislature to put an end to the present unsatisfactory conditions.

The Analytic Idea.

ONE way of making caviare acceptable to the general is to express the magnificent in terms of the commonplace. If there is no wonder for us in the sea, no beauty in the earth, we are helped to amaze by being told that they are composed respectively of "little drops of water, little grains of sand." "What a piece of work is a man!" and he has been reduced to his essentials. A German, needless to say, has worked it out. A 150-pound human being is worth £1 11s. 3d. That is in terms of his constituent elements. "His fat is worth 10s. 5d.; of the iron there is hardly enough to make a nail an inch long. There is sufficient lime to whitewash a pretty good-sized chicken house. The phosphorus would be sufficient to put heads on 2,200 matches, and there is enough magnesium to make a pretty firework. The average human body contains enough albumin for 100 eggs. There are possibly a teaspoonful of sugar and a pinch of salt." At first sight we seem to have found a useful outlet for our surplus population. To turn the unemployable into whitewash and get the unemployed to apply it to our chicken houses sounds simple, but it is not. For the elements are so mixed in us that, when Nature sets them up and says this is a man, it would cost more than our £1 11s. 3d. to turn our substance to any baser uses. It is bad luck that when we have done with our bodies we cannot hand them over to the hardware dealer, but it is our fate. Dust we are, and we remain the quintessence of dust.

Making Plain the Crooked Path.

"SYPHILIS is at once the lightest and the most terrible of diseases, which causes more misery in our civilisation than that of any other." So says "Civis," in this month's *English Review*. "Civis" has written an article in a widely read magazine that should do a great deal of good. He has told the truth about syphilis, and has pointed out that, though terrible if neglected, the disease is one of those that are most amenable to treatment. "Civis" says what he has to say clearly and fearlessly. There is nothing new or startling in the article—indeed, the average doctor may find it rather dull, as it tells him nothing he did not know before, nor does it bring a single new idea to help to solve the problem of venereal disease. Its value is extrinsic. It is written to be understanded of the people, and it is published where the people can get hold of it. That is what we want. We know enough about venereal disease to tackle it successfully if we get the chance. Hitherto we have not had the chance. It is articles such as this that are our opportunity. Syphilitic ignorance is bliss till secondary symptoms occur. Simple knowledge of the disease spread far and wide through the laity will bring them to us. The people know us well enough to be sure that we are not raising a scare for our own pecuniary advancement; and, when they have had it dinned into them often enough that syphilis wants treatment, and that treatment cures syphilis, they will come to us for the help that we can give. The publication of such information can do nothing but good. and it can do the greatest good. We are ready and waiting to get rid of syphilis, as we have got rid of other diseases; we have the means, the power, and the will, and let us hope that we will soon have the opportunity.

The Merry Heart.

THE beneficial effect of keeping up the spirits of a patient who is wont to become depressed is well known. In fact, "to exhilarate the heart," says Burton, "has been the practice of every age and country as the best means of preserving life." Regarded as a psychological state, laughter has been thought to be merely the expression of the overflow of nervous energy, but this shows itself in many other ways than in visible mirth. According to Dr. W. McDougall, of Oxford, who read a thoughtful paper upon the subject last week at a meeting of the Subsection of Psychology of the British Association at Birmingham, laughter is Nature's protection against the depressing effect upon the system of our sympathetic tendencies. It may seem very illtimed, but most of us manifest a desire to laugh when we see a person fall down, for instance. Our kindlier feelings, however, soon prevail and, controlling our risorial muscles as best we can, we hurry to the spot to render assistance. Probably, if we did not give vent to our first impulse, the "useless minor sympathetic pains," referred to by Dr. McDougall, would become too much for us, and the length of our faces would daily increase. Medical men ought, therefore, to be the cheeriest of all people and the most readily moved to laughter. But it is because of the changed direction of mental outlook induced by cheerfulness and mirth which interact powerfully even upon physical conditions that a "merry heart doeth good like medicine." The old saying of Marsilius Ficinus—"for without mirth physic is of no force"—may be heartily commended to the notice of all medical practitioners as well as psychologists.

Rags and Bones.

HALF the world does not know how the other half lives. A good deal of unexplored territory still remains to be gone over by the would-be sensational journalist or by the ardent philanthropist. We really know very little about the thriving industry known as the "rag and bone" trade, the very life of which, it is reported, is in danger of extinction, if certain new regulations put forward by the London County Council are approved by the Local Government Board. Though the handling and storing of old rags can hardly be regarded as a choice occupation, yet the dealers in this business do not appear to suffer in health to a greater extent than, say, scavengers or fell-mongers. It is true that, in the interests of public health, more attention seems to have been paid to the alleged injuries to health inflicted by the mere proximity of premises where "offensive trades" are carried on, than to the effect upon the workers therein. Infection may, of course, be conveyed by old clothes and rags, but these do not become more offensive or unwholesame from decomposition as would fat, bones, and skins. It should not be impossible to provide for the adequate sterilisation of old rags without injuring the trade of the marine store dealers. The lot of the small hawker who enlivens the suburban street with his raucous cries of "Any rags?" or "Old Clo'!" is less enviable, because the collection of animal matter, even in the ossified state, is at present an undoubted infringement of sanitary laws, so that his "speciality" will, in all probability, need a good deal of reorganisation. No doubt the large soap-makers, bone-boilers, and manufacturers of artificial manure and glue will have something to say if any shortage of raw material should be threatened by any modification of the work of the London rag and bone men.

Green Vegetables in the Treatment of Diarrhœa.

The value of the cooked stems and leaves of certain vegetables in the diet is indisputable. Their anti-scorbutic and gently laxative properties render them useful food adjuncts, but it sould be remembered that their actual food value is relatively low. A novel use for greens is described by Dr. Cunningham Wilson, of Birmingham, Ala. *(a)*, who has been treating for all chronic diarrhœas and cases of acute diarrhœa and dysentery that have resisted ordinary methods, with a diet of spinach, turnip greens and mustard tops, with the most gratifying results. The method has been adopted by the author for the last nine years, and it is stated to be so simple and to give such a measure of relief that patients are willing to continue the treatment as directed. A tablespoonful or more of spinach, turnip or mustard tops is given four times a day for one to two weeks, no other food, save a little dry toast, being allowed unless patients become very anxious for it. At first the stools show the undigested food, but immediately following this the motions become more solid, and at the same time flatulence and tenesmus disappear when these symptoms have been present. The author's first experience of this treatment was confined to chronic conditions, but later he found that equally good results could be obtained in acute dysenteries which failed to respond to salts or opium and oil. The spinach is thoroughly well cooked, and is generally well tolerated. The use of the greens is advised for some few weeks after the patient has got on to regular diet. The method certainly appears simple, and should be accorded a wider trial.

PERSONAL.

Dr. William Arnott Dickson, M.D., Ch.B.St. And., F.R.C.S.Edin., D.P.H., has been appointed Tuberculosis Officer for Gloucestershire.

Dr. Hideco Noguchi, of the Rockefeller Institute for Medical Research, New York, is reported to have discovered and cultivated the specific organism of rabies.

Sir James Crichton-Browne delivered the thirteenth Presidential Address last week at the Annual Conference of the Sanitary Inspectors' Association at Llandudno.

Dr. Trevor Berwyn Davies, M.D., B.S.Lond., B.Sc., M.R.C.P.Lond., has been appointed Registrar and Pathologist to the Hospital for Women, Soho Square, London.

Dr. E. Burnet, formerly Medical Officer of Health for Leamington, has been selected as prospective Liberal candidate for the united boroughs of Warwick and Leamington.

Dr. Francis Warner, whose retirement from the post of Senior Physician to the London Hospital was announced a few weeks ago, has been elected Consulting Physician to the Hospital.

A drinking fountain was unveiled the other day at Ballinasloe as a public memorial to the late Dr. Rutherford, who practised in that town for nearly forty years prior to his death in 1911.

Dr. A. R. Urquhart, Physician Superintendent of the Murray's Asylum, Perth, has recently intimated his resignation to the directors for health reasons. He was appointed to the position in 1879.

Dr. John Dean Buchanan, of Blackburn, has been appointed Medical Officer and School Medical Officer for Lancaster in succession to Dr. Joseph Cates, who has been appointed to similar positions for the county borough of St. Helens.

Dr. J. Walton Browne, LL.D., M.D., late Senior Surgeon to the Royal Victoria Hospital, Belfast, has been appointed a Deputy Lieutenant for the County of that City. We heartily congratulate Dr. Browne upon the honour so deservedly bestowed upon him.

Sir Rickman Godlee will confer the Fellowships of the American College of Surgeons at the first convocation of the Institution, to be held at Chicago on November 13th next. About 1,400 prominent surgeons of the United States and Canada are to be created Fellows.

Dr. John Lewis Thomas, of Harefield, Bitterne, Hampshire, formerly Senior House Surgeon at the Nottingham General Dispensary, and who died on June 10th, aged 66 years, left estate of the gross value of £6,110 2s. 2d., of which £5,978 19s. 8d. is net personalty.

Sir William Macgregor, G.C.M.G., Governor of Queensland, who last week celebrated the twenty-fifth anniversary of his appointment as Colonial Governor, was at one time attached to the medical staff of the Glasgow Royal Infirmary, and also to that of the Royal Lunatic Asylum, Aberdeen.

Dr. Frank Lang, of Sunderland, is retiring, we understand, after having been in practice in that town for the long period of 55 years. Dr. Lang, though he has reached the advanced age of 84, is still brisk and active, and there is a general hope amongst his many friends that he may long enjoy his well-earned rest.

Prof. Jastrow, of the University of Pennsylvania, the well-known Assyriologist, will deliver a lecture upon "Babylonian Medicine" at the Royal Society of Medicine (Historical Section), on Friday, October 10th, at 5 p.m. All members of the profession, as well as students, interested in the subject are invited to attend.

CLINICAL LECTURE

ON

FUNCTIONAL DISORDERS OF THE HEART.

By ROBT. OSWALD MOON, M.D.Oxon., F.R.C.P.Lond.,

Physician to the Hospital for Diseases of the Heart; Assistant Physician, Royal Waterloo Hospital.

IMPORTANT and frequent as are the various structural lesions of the heart whether of the valves or of the muscle itself, perhaps in ordinary clinical work we more often meet with cases which, while presenting morbid affections in the region of the heart, show on examination no structural lesion either of the valves or of the cardiac muscle. In fact, when a patient comes complaining of palpitation of the heart or pain in the region of the heart, there is considerable likelihood of the condition not being connected with any organic lesion at all, but being merely due to some functional derangement of the heart. So I thought it might be profitable for us this afternoon to go over some of the more common functional disturbances of the heart, and we will begin with palpitation.

Palpitation of the heart.—By this is meant a morbid consciousness of the beating of the heart, that is, each beat of the heart awakens in the patient a painful sensation; when severe there is a sense of constriction of the throat, an indefinable feeling of anguish, the heart seems as though it would break through the chest wall, the face becomes pale, is covered with sweat and the extremities are cold. These symptoms may of course occur in connection with, or be indicative of, an organic cardiac lesion, but it is far more common to meet with this symptom by itself where no cardiac lesion is to be detected.

In fact, this condition is so often met with apart from any organic lesion of the heart, that when a patient comes complaining of palpitation, and of palpitation only, the probabilities are considerable that nothing will be found amiss with the heart. As has been well said by Potain, "*Tout malade qui consulte pour des palpitations doit être présumé exempt de maladie du cœur,*" and, a century earlier, Senac had said "*Les palpitations surviennent principalement dans les maladies où il n'y a aucun vice du cœur.*" Sometimes there is a certain periodicity about these attacks of palpitation, and they will occur punctually at the same hour of the day. They may last for a few minutes or an hour or two. Occasionally the attack of "palpitation" is accompanied by "heart fear" (Herzangst), and these two sensations may present many points of resemblance to some forms of angina pectoris.

Causes.—(1) Dyspepsia, and more particularly flatulence, are probably the most common causes of palpitation of the heart, so that the first thing to do when a patient comes complaining of palpitation is to consider the condition of the stomach and intestines. In these cases, if one presses forcibly with the fingers in the fourth left intercostal space of the præcordial region, one finds a point where the pressure evokes a cry from the patient, and this by French writers is thought to be specially significant of the dyspeptic origin of the palpitations.

(2) Tobacco, which may cause palpitations not only to those who smoke, but to those who are engaged in the manufacture of tobacco; the effect of the nicotine is to lower the blood pressure and to render the heart's action rapid and irregular, thus giving rise to palpitations.

(3) *Tea and coffee in excess.*

(4) *Keen emotions*, such as fright or anger; these are most frequent causes of palpitations. A case came before me recently of a woman, aged 21, who had been suffering from palpitation of the heart and a choking sensation off and on for the past year. She had had rheumatic fever at the age of 13, and there were *signs* of mitral regurgitation, but there had been no cardiac *symptoms* till a year ago, when she had had a severe emotional shock.

(5) *Conditions of neurasthenia and cerebral overwork.*

(6) *Hæmorrhage and conditions of anæmia* by lowering the blood pressure accelerate the heart beat, and so give rise to palpitation.

(7) *Early pulmonary tuberculosis.* In the early stages, when there are no physical signs in the lungs, it is important to recognise this as a cause of palpitations; if in such cases the arterial tension is below the normal, then the diagnosis of tuberculosis becomes very probable.

(8) *Excessive consumption of carbo-hydrates* would seem sometimes to cause palpitations. It is necessary to distinguish true palpitations from false; in the latter the thorax presents a condition of hyperæsthesia such that whenever the heart contracts the shock at the apex awakens a painful sensation, even when the beats are not more precipitate or violent than in the normal condition. One must also distinguish true palpitations from the little shocks and tremblings which are sometimes met with in the thoracic walls in the case of nervous and hysterical subjects. One must remember that nervous individuals are conscious of processes which in the healthy do not penetrate the sensory sphere; the threshold of sensation is at a much lower level in a nervous patient.

Prognosis is usually good, unless the palpitations are associated with an organic disease of the heart or with Graves's disease; in most cases they disappear with the removal of the cause, but no doubt obstinate conditions of dyspepsia and neurasthenia or hysteria may resist all our efforts.

TREATMENT.

Rest, physical and mental, is generally indicated. A stay in the country away from the stimulating, over-exciting atmosphere of a large town may be all that is required. On the other hand, complete idleness is seldom beneficial, and a patient recently under my care definitely alleged that he was always better when doing his work; much, of course, depends on the diagnosis which one makes of the psychic condition of the patient. Speaking generally. it is well to insist on regular exercise in moderation, and particularly on regular hours of sleep.

Hydrotherapy is most useful for the more robust patients in the form of the morning cold bath, the cold douche, or warm hydrotherapy in the form of jet douches.

Drugs.—Bromide will always be found useful in those cases connected with a general nervous erethism; sometimes it may be well combined with belladonna. Valerian often gives relief; it is best administered in the form of valerianate of ammonia. In the more asthenic cases quinine and dilute hydrobromic acid are often helpful. When, as is sometimes the case, palpitation is accompanied by high tension, it will be relieved by sod. nitr. gr. 1, with tinct. aconite m. v. t.d.s. Patients often wake up in the middle of the night with troublesome palpitation, which may be avoided by taking a dose at bedtime of the following:—

℞ Pot. Bicarb., gr. xv.
Sp. Ammon. Aromat., ʒss.
Aq. Menth. Pip. ad ℥i.

In certain cases in which the digestive system is unaffected small doses of digitalis may be given for a few days, not for its tonic, but for its sedative action.

Tachycardia.—This differs from palpitation in that it is a purely objective symptom which is perceived by the doctor and is perhaps completely unrecognised by the patient. The causes are very similar to those of palpitation; here, too, emotion plays an important part, as do also tea, coffee, and alcohol; in the latter case the tachycardia seems to be due to a neuritis of the vagus nerve. Often tachycardia is an early indication of tuberculosis or of Graves's disease; in the latter case the rapid, excitable action of the heart may for long be the only evidence of a latent hyperthyroidism. It is also frequent after hæmorrhage because the blood pressure is notably diminished, and the heart beats quicker as it has less difficulty in emptying itself. Perhaps the most common cause for tachycardia is some gastro-intestinal disturbance connected sometimes with enteroptosis, and this when frequently repeated may ultimately cause disease of the myocardium and of the coronary circulation. Closely connected with the tachycardia of gastro-intestinal origin is that curious condition known as "paroxysmal tachycardia," in which, without any warning, the heart seems suddenly to lose all control and to beat with astonishing rapidity, anything from 160 to 300, so that the pulse at the wrist often becomes uncountable. The peculiar feature of this condition is the suddenness of its onset and its equally sudden disappearance; as a rule, the beats are regular and there is no arrhythmia; what is still more peculiar, however, is that the patient is often so comparatively little inconvenienced by what is undoubtedly a somewhat serious condition. The attacks may last for a few hours or a few days, or even for several weeks. In my experience 24 to 36 hours is an average time for one of these attacks; the patient, though feeling uncomfortable and somewhat distressed, will still be able to continue his work. As a rule, there is no organic lesion associated with this paroxysmal tachycardia, but I have myself met with it in a case of aortic disease and also of mitral stenosis, and in one case which came to an autopsy a very large patent foramen ovale was found; however, in all these cases the attacks of paroxysmal tachycardia seemed to be quite independent of, and to have no direct relation to, the organic cardiac lesion.

The immediate causation of the attack is very uncertain; patients themselves will often attribute it to some sudden exertion or condition of indigestion. Of its nervous origin I have recently had an example in the case of a young woman, aged 23, who was an in-patient at the Heart Hospital for some weeks with paroxysmal tachycardia; whenever any mention was made of her going out of the hospital by the house physician or the sister, an attack would immediately start off.

Prognosis as regards life may be regarded as favourable. Some few years ago I saw a member of our profession, aged 70, who had suffered from these attacks for some years without great inconvenience. Generally the attacks become less frequent and less severe with advancing years. At the same time one must realise that the attacks themselves are evidence of the heart not being entirely sound, and when an attack of this kind lasts several days, or even weeks, there is great danger of dilatation of the heart, which may become permanent with all the symptoms of backward pressure supervening—pulmonary congestion, œdema of the feet, etc., with a fatal termination, so that even with regard to life our prognosis must be guarded. The general outlook must be based on the heart's power of reaction to moderate effort in the intervals of the attacks. On the whole, if the heart does not increase in size and the attacks are of short duration, the prognosis is good. We are often asked the question, "Can the condition be cured so that there shall be no recurrence of the attacks?" In the present state of our knowledge a distinct negative must be returned to this question. In many cases the frequency and severity of the attacks may be reduced by treatment wisely conducted, but their permanent arrest is too infrequent to justify us in holding out uncertain hopes. The question often arises whether such patients should be allowed to go on with their work. Unless the attacks are becoming more prolonged, or signs of dilatation have manifested themselves in the interval, it does not seem reasonable to interfere with a patient's means of obtaining a livelihood. Speaking generally, the less frequent the attacks the longer they last. As a rule, the attacks in the case of any given patient are of about the same duration.

Treatment.

During the attack.—Lower the head and elevate the legs. The application of an icebag to the heart nearly always affords some relief. There are patients who find that they can arrest their attacks by taking iced water or strong coffee; I have found the administration of an emetic to be more useful, acting on the suggestion of a patient who found that vomiting always relieved him, but it has a depressing effect and is not to be generally recommended. Some relief may be obtained by making the patient press the elbows into the sides, and at the same time making pressure on the abdomen. Compression of the trunk of the vagus in the neck has been said to be efficient in arresting the attack; if this is not successful, galvanisation of the nerve may be tried. Sometimes by making deep swallowing movements the inhibitory action of the vagus nerve is stimulated, and the attack is arrested. Drugs given during the attack seem to be of very little use; digitalis given in fairly large doses I have not found to have any satisfactory effect upon the rapidity of the cardiac action; occasionally I have had good results from erythrol tetranitrate (gr. ¼, IVtis horis), and it seems worth trying.

In the intervals of the attacks special attention should be paid to the digestive system, as the seizures seem often to arise in connection with some gastro-intestinal disturbance. Alcohol and tobacco should certainly be avoided, and tea only taken in strict moderation. There seems no reason why the patient should not take ordinary exercise or follow his occupation, provided it is not exceptionally arduous. The continual wearing of an abdominal belt in the daytime has been recommended by Dr. Lewis. As regards drugs, it has seemed to me that a combination of bromide of potassium with tincture of hyoscyamus has reduced the frequency of the attacks.

The nervous heart has to be diagnosed mainly by the subjective symptoms; the important objective symptoms are fluctuations in rhythm extending over considerable periods of time and the association of irregularity with unpleasant, indefinable sensations in the cardiac region. But of course great caution must be exercised in making the diagnosis of "nervous heart," especially in those who have passed the fortieth year, for we have to differentiate the following conditions from a nervous heart:—(1) Sclerosis of the coronary arteries; (2) chronic myocarditis; (3) some forms of the alcoholic heart. A further difficulty is that patients with changes in the coronary arteries and the myocardium not infrequently develop nervousness; they begin to worry about the disease and anxiously watch for every heart-beat.

Prognosis.—The disease has no direct influence on the duration of life; on the other hand, complete recovery is infrequent. In the case, however, of coronary sclerosis the patient's life is in danger of being terminated at any moment, while myocarditis carries with it a gloomy outlook.

Treatment is largely that for neurasthenia or hysteria, when one can be sure that the heart is unaffected. In these cases it is important to stop excessive mental and physical labour, and specially that form of excessive physical exertion which is carried on under the guise of athletics.

Pseudo-angina is an unsatisfactory term, as there is no fundamental resemblance to true angina, so that there ought to be little difficulty in diagnosing between them. Sometimes it is termed "angina vaso-motoria," but this is too narrow a definition, because these conditions may not be always due to vasomotor changes. It is far more frequent in women than in men and in comparatively young women. While true angina almost invariably makes its first appearance after some definite exertion, this minor form usually comes on for the first time when the patient is quietly resting. In several cases that have come before me there has been a definite history of some emotional disturbance which seems clearly to have been the starting point of these minor attacks.

The seizure may last for perhaps two or three hours, and, though the pain may be severe, it is never so agonising as in true angina, nor is there the sensation of impending death. Patients may, however, become unconscious for a quite considerable length of time. Usually there is no organic cardiac lesion, and in my experience the patients have seemed in other respects healthy.

The pain in pseudo-angina tends to radiate centripetally rather than centrifugally, as in true angina; thus the attack often begins with tinglings and shooting pains in the upper limbs, which then pass to the præcordial region; it would seem sometimes as though the sympathetic were implicated.

The pain is less fixed and more diffuse than in the true angina; the sensation experienced by the patient is that of fulness, tension or weight in the stomach, the heart feels too big but the sensation of being grasped in a vice is quite exceptional. The attacks often exhibit some periodicity; generally they occur when no effort is being made, or are preceded by slight troubles such as vomiting and nausea. In specially nervous subjects the attack may terminate with a sort of hysterical crisis, such as an outburst of tears or the passage of a large quantity of clear urine. In the case of men this may often be associated with excessive tobacco smoking, and is known as tobacco angina.

Prognosis is entirely favourable; death in an attack has been known to occur, but such cases are very rare. On the other hand, the symptoms may prove very resistant to treatment, and, if the underlying neurosis be not judiciously handled, the patient may drift into a condition of chronic invalidism. This, however, is quite the exception; most cases get entirely well.

Treatment.—As with true angina, so in these cases, when there is clearly arterial spasm during the attack, amyl nitrite is indicated; similarly when there is no such spasm, it may be necessary at times to administer morphia subcutaneously, but this ought to be quite exceptional. If the body is cold it is well to apply heat to the trunk and the extremities, and to administer ammonia or other diffusible stimulants.

It is important to treat constipation and flatulence; almost any kind of digestive disturbance may give rise to this form of angina. It is well to avoid too tight skirtbands. Massage is often useful in these cases, and I have found the artificial Nauheim baths give very good results.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by James Sherren, F.R.C.S., Surgeon to the London Hospital, and to the Poplar Hospital for Accidents. Subject: "The Diagnosis of Chronic Ulcers of the Stomach and Duodenum."*

ORIGINAL PAPERS.

EXPERIMENTAL OBSERVATION ON THE REPAIR OF FRACTURES AND THE INFLUENCE UPON IT OF VARIOUS OPERATIVE PROCEDURES. (a)

By ERNEST W. HEY GROVES, B.Sc.Lond., M.D., F.R.C.S.Eng.,

Lecturer on Surgery, University of Bristol; Assistant Surgeon, Bristol General Hospital.

IN the endeavour to ascertain from experimental evidence the best method of fracture repair, a large amount of pathological material has been accumulated which has a general as well as a surgical interest. Nearly all my experiments have been done on cats, a few only being on rabbits.

Immobility in relation to repair.—There is a generally accepted theory that a certain amount of movement is almost necessary to repair, and this has by many been extended to imply that the movements of the bones at the site of fracture is positively desirable and beneficial. I have been quite unable to gain any experimental evidence of the truth of these theories.

Mobility in relation to callus excess.—But if there is doubt whether fixation and immobility ever conduce to want of repair, there is no doubt that mobility and faulty fixation lead to callus excess.

In cases where fixation allows a moderate but strictly limited movement, *e.g.*, where intramedullary pegs are used, there is found a callus condition, intermediate between that of absolute fixation and that of free mobility.

Callus excess produced by chemical stimulus.—In addition to mobility, any irritant, if not so severe as to injure the tissues, will cause a callus excess. The most remarkable means of exhibiting this is by means of pegs made of metallic magnesium. Within four or five weeks there occurs the almost complete absorption of the metal and the growth of a big callus deposit which becomes ossified very early.

(a) Abstract of Paper read at the International Congress of Medicine, London, 1913.

The production of a false joint.—In four cases a false joint has resulted from a failure of the method of fixation. Three of these were in femurs and only one in the tibia, the latter being in a rabbit, in which animal the fibula is so small and fragile, that it gives but little support to its fellow bone.

In all these cases, therefore, there was only one bone in the affected part of the limb—the method of fixation (plates in two cases and pegs in two) had given way early, and, as I used no external splints, there was free mobility from the outset. It seems only to be a question of degree whether a given mobility will produce a false joint or a vicious union with callus excess.

The rôle of cartilage in callus repair.—It is well known that cartilage takes a large part in the repair of fractures in animals, and the statement that it does not do so in man is possibly an assumption derived from insufficient opportunity for examination. The great bulk of callus is at one time laid down as cartilage, and that in the ossification of this cartilage the change begins at the margin of the bone fragments and thence invades the rest of the tissue.

I have never seen ossification beginning under the periosteum. At a later stage the zone of cartilage remains along the line of fracture after all callus elsewhere has ossified.

On the screwing of bones.—It has become the fashion lately to regard the fixation of fractures by plates and short screws as the routine procedure for cases requiring operation. But it does not need a very lengthy experience to prove that this method has drawbacks as well as difficulties.

Within a few weeks the majority of such plates become loose, the screws falling out into the soft tissues. Then, whether the object of the operation is attained depends simply on whether the screws have held long enough for callus fixation, and when the screws and plate once become loose, they usually cause a serious effusion, which breaks through the skin, becomes infected, and causes a sinus, which demands the removal of the foreign bodies.

All the experiments I have done fully confirm this clinical experience. In every case the screws worked loose from one end or another and displacement occurred.

In human surgery this tendency to displacement is combated by the use of retentive splints after the operation, but this will involve immobility of joints and muscles, which it should be one of the objects of operative treatment to avoid. The short screw, which only bites by a sharp edge into a thin plate of hard bone, will inevitably pull out within one or two weeks if it is subject to much tension.

Fixation by perforating screws or pins.—A screw or pin, in order to take a firm hold of the bone and secure a grip which will not soon give way, must go through a whole thickness of the bone and hold by means of a nut or turned-over ends. Such fixation will remain permanently or for an indefinite time. There has been an idea that plates and screws become loose and are extruded, simply because there are foreign bodies or because sepsis has been introduced with them. I think this is borne out by the facts of experiment. A large plate firmly fixed will remain in place indefinitely, whilst a small plate and screws which work loose soon cause a sinus and have to be removed.

On direct methods of fixation.—Methods of fracture fixation which do not involve direct exposure of the seat of injury give the most ideal results. Rapid union with minimum callus formation occurs with perfect regularity. In particular the formation of the internal callus takes place under these circumstances with much greater nicety than when the fracture ends have been much manipulated.

Relation of the periosteum to the repair of fractures.—In a number of my experiments, I have endeavoured to ascertain the *rôle* of the periosteum in the reparative process. In simple fractures in which the ends of the bone were surrounded by a thin sheet of metal which was placed beneath the periosteum so as to exclude it, it will be seen that repair has followed a normal course. In a tibia shown ten days after the operation the surface of the bone is seen to be rough and pitted, and it is covered by granulation tissue. This is the early stage in the laying down of external callus, which is taking place from the bones, separated from its periosteum. In a tibia 20 days after the operation, cut down the middle, it is seen that the callus is well advanced in its formation under the plate, and that it is extending from the ends of the plate under the periosteum.

In studying the phenomena of repair in comminuted fractures, I found the double transfixion apparatus of great service in keeping the bones in good position, and I consider that such an appliance is of the greatest practical utility in the treatment of both compound and comminuted cases. If the fragments are removed, the periosteum restored to its position, and the ends of the main parts of the bone kept apart at their original distance, repair hardly occurs at all, or very slowly. In a tibia 42 days after such treatment it is seen that the union is by fibrous tissue only, and the little bone tissue that is growing with this is sprouting out from the bone ends, and not being laid down from the periosteum.

These experiments are in complete accord with Macewen's observations. They show that the periosteum itself lays down no new bone. New bone formation occurs from the cut surface of the bone, either from the main shaft or still more rapidly from separate fragments. Still the periosteum has an important *rôle*, inasmuch as it is the chief vascular supply to the area of repair. If it is excluded from this, the callus can only receive nourishment from the two ends of the area involved, and not from the side, and therefore repair is slower and weaker than is the case when the periosteum is in its normal position.

Summary of Conclusions.

1.—Screws which merely bite into the side of the bone will rapidly loosen by a process of bone absorption, if they are subjected to much tension. They are therefore unsuited for the operative treatment of fractures.

2.—Absolute fixation of fractured ends is conducive to good repair.

3.—The only way in which fractures can be firmly united by plates is by the use of pins, screws, and nuts which perforate the whole thickness of the shaft.

4.—Great mobility of the ends of a fractured bone is likely to produce a false joint, especially in the case of a single bone like the femur.

5.—Marked mobility of the ends of a fractured bone cause a great excess of callus.

6.—Metallic magnesium is absorbed in a bone and causes great callus excess.

7.—Indirect methods of fracture fixation give the most ideal results, and this is the only method possible when dealing with compound and comminuted cases.

8.—The periosteum has no power of forming callus or new bone.

9.—The periosteum is of great value in serving as the chief blood-supply to the callus and in limiting its extent.

10.—Active callus and bone formation always occur from the broken surface of the bone and every small fragment acts as a centre of new bone growth.

SYPHILITIC DISEASES OF JOINTS AND BONES IN CHILDHOOD—THEIR DIFFERENTIAL DIAGNOSIS FROM THE MEDICAL STANDPOINT. (a)

By SYDNEY A. OWEN, M.D.,
Assistant Physician, West London Hospital.

Mr. Addison has recently outlined for us, from the surgical standpoint, the more common bone and joint lesions which may be met with in infancy and childhood of a syphilitic nature. Clearly it is important to realise that the so-called specific epiphysitis of infants is really a lesion of the diaphysis rather than of the epiphysis. I am not surprised to hear this lesion frequently occurs apart from other manifestations of the disease. This is quite in harmony with my own experience. I think one of the main reasons why so many of us tend to overlook syphilis in young subjects is because we expect to find classical signs of congenital syphilis in conjunction with the particular lesion we are considering.

The Wassermann reaction.—Inasmuch as a positive Wassermann reaction, if performed in accordance with one of the recognised methods, affords almost certain proof of syphilis, the importance of employing this test in doubtful cases, where opportunity offers, cannot be over-estimated. From my own investigations I would say a very high percentage of congenital syphilitic children give a strongly positive Wassermann reaction, so that a negative result is stronger evidence against congenital syphilis than is the case when we are dealing with acquired syphilis of older persons. Further, once a positive reaction is present, treatment with mercury is of less avail in converting it into a negative reaction. As a guide to treatment, therefore, the repetition of the test is not of such great value.

I have been asked to draw your attention to some of those conditions which the physician conceivably may confound with syphilitic bone and joint disease in infancy and childhood. As the time at my disposal is limited, I will endeavour to confine my attention to a few conditions and not to attempt to cover the whole ground.

In infants under one year no joint affection, with the rarest possible exception, is due to rheumatism.

Putting aside suppurative lesions for consideration by members who are interested in the surgical aspect of the question, confusion is likely to arise in *atypical cases of infantile scurvy.* Common to both we have swollen, tender limbs and pseudoparesis. Some distinctive features are as follows. (1) The syphilitic lesion *as a rule* occurs at a much earlier age. (2) Scurvy bears a definite relation to certain patent foods and condensed milk. (3) In scurvy the lesion is more likely to be symmetrical, and the demonstrable physical signs point to a lesion of the shaft rather than of the end of the bone. (4) Spongy gums, subconjunctival hæmorrhages, epistaxis, hæmaturia, and melæna do not occur in syphilis. (5) The constitutional state in recent scurvy is more frequently good; in the syphilitic infant *marasmus* may be a concomitant. (6) Whilst an appearance suggestive of "raising of the periosteum" in the X-ray plates is common to both, the bony changes met in syphilis do not occur in uncomplicated cases of scurvy. I hope some of our guests here to-night and members will tell us the earliest age that they have met with infantile scurvy. Can the swelling of a large bone such as the femur, existing alone and in the absence of other confirmatory signs, be due to scurvy? Has anyone any experience of scurvy in breast-fed infants or in infants fed on unboiled cow's milk?

In marasmic infants, especially those suffering from chronic enteritis, or in infants previously healthy but recovering from an acute summer diarrhœa, an œdematous condition of the lower tibiæ and puffy feet can hardly be mistaken for a lesion due to syphilis if the condition is borne in mind. In such cases tetany is a not uncommon concomitant.

In children who have reached the "walking period" I would draw your attention especially to (1) the hyperæsthesia, subjective pains and pseudoparesis seen, not infrequently, in fat, *rickety* children. As a rule the evidence of rickets is forthcoming: the physical signs in the shafts, epiphyses and skull-bones are characteristic. There is no swelling and no œdema. Where syphilis and rickets are combined the diagnosis is sometimes, for a while, very difficult. (2) The acute hyperæsthesia, the toneless, flabby state of the muscles, which may precede for a short time the definite onset of paralysis and loss of deep reflexes in cases of early *poliomyelitis* must be borne in mind, especially where the typical constitutional symptoms and the early onset of definite palsy are in abeyance.

Injury.—I am afraid I must acknowledge falling only too recently into the error of mistaking for a fracture with effusion of blood a gummatous periostitis at the upper end of the humerus in an infant, aged four months, where the well-being of the child, the absence of confirmatory evidence of syphilis and all constitutional symptoms, in addition to the history of a definite injury, led me astray. I have made, too, the opposite mistake of thinking that a traumatic periostitis in a boy, aged 11, at the lower end of the radius and ulna was due to syphilis where the history of injury was not forthcoming at first, and where a negative Wassermann reaction and rapid complete recovery, apart from treatment with mercury, showed that the diagnosis of syphilis was, in all probability, quite incorrect.

If we bear in mind two or three well-established clinical facts with regard to *rheumatism* in children, we shall not be likely to fall into the error of confounding a rheumatic joint lesion with other affections, of which syphilis and tubercle are two very important causes. May I remind you (1) that true rheumatism is practically unknown in infancy; (2) that the arthritis is usually the least obtrusive sign of the rheumatic symptom-complex in children; (3) that the absence of grave constitutional symptoms and high fever is the rule and not the exception; (4) that the co-existence of any evidence of endocarditis, myocarditis, or pericarditis, choreiform movements or nodules point to rheumatism as the cause of an arthritis, however anomalous the joint lesion may be. Where acute rheumatism commences with monarticular involvement of a large joint, such as the hip or shoulder, without any evidence of endocarditis or nodules, etc., the differential diagnosis is a matter sometimes of extreme difficulty. Time, and careful observation from day to day, can alone decide the true nature of the affection. In my experience the therapeutic test of salicylates does not always give the assistance we need and sometimes expect. I should like to hear from Dr. Still the earliest age at which he has met with acute rheumatism.

(a) A paper read before the West London Medico-Chirurgical Society on March 7, 1913.

Osteo-arthritis and rheumatoid arthritis.—I have never had under my own care a case of Still's disease. I hope we may hear more from Dr. Still of this interesting disease and concerning those forms of destructive bone lesion resembling osteo-arthritis of the adult. I think I am right in stating Dr. Still believes the latter to be due in some cases to syphilis. (*a*)

In *purpura rheumatica* so-called, painful swollen joints and œdematous limbs are met with. We are here dealing, in all probability, with some toxic blood state. Although the symptoms and signs at first may be indistinguishable from hæmophilia, the two conditions are fundamentally different. Grave constitutional symptoms, high fever, spongy gums, and a septic mouth assist in the diagnosis.

A typical case of *erythema nodosum* should give rise to no difficulty in diagnosis. The appearance of the rash may be preceded by pain in the limbs. The eruption itself consists of large oval swellings of a rosy red tint. The extensor surface of the limbs is the site of election. They may be exquisitely tender; rarely they may be so soft as to give rise to the sensation of semi-fluctuation. The forearms and other parts of the body may be attacked. They tend to occur in crops. Though frequently occurring in rheumatic subjects, it is well known how refractory they are to salicylates. They may or may not be accompanied by recurrent and migratory joint swellings. In tubercular subjects typical lesions are seen.

In *leukæmia*, especially the acute form, joint swellings and œdema, for instance at the lower end of the tibia, are occasionally seen. I recall the case of a male child, aged four, who was brought for wasting, pallor, and "rheumatic pains" in the fingers, arms, and legs. All the superficial glands were prominent; the spleen was enlarged. The left ankle-joint was swollen. There was a tender œdematous swelling at the lower end of the left tibia. The child was wasted, pallid, acutely ill with septic gums. A blood-count showed 3,800,000 reds and 31,500 whites, with 95.25 per cent. of lymphocytes. After admission the wrists and shoulder-joints were painful; the temperature varied between 101 deg. and 105 deg. F. At the *post-mortem* the typical changes associated with acute leukæmia were found.

Gonorrhœal arthritis.—Mr. Clement Lucas, in 1885, I believe, first drew serious attention to this condition. Despite the fact that the eye condition is so common in infancy, the joint complication is a far from frequent event. There would appear to be two forms: (1) an acute one, with features suggesting suppuration; and (2) a milder form, accompanied by a great deal of effusion and pain on movement, but with little or no surface redness. (*b*)

Extension of the swelling beyond the joint cavity is apt to occur. Effusion into the tendon-sheaths has been noted by Mr. Sydney Stephenson. The knees and wrists are the joints most commonly involved; in other cases the shoulder and elbow. The prognosis is favourable if suitable treatment for the eye condition is carried out. The co-existence of ophthalmia in a case of this type points to the true diagnosis of the joint lesion.

Clutton's symmetrical synovitis.—We are all familiar with these cases of synovitis, painless as a rule, to which Mr. Addison has alluded in his paper. It is usually stated to have the same age-period as interstitial keratitis. Sometimes it is associated with that condition. I should like to hear from members of the Society the earliest age at which this condition may occur. What is the frequency with which interstitial keratitis is found associated with it? Are symmetrical swellings of joints other than the knees and ankles common?

The most recent instance I have seen of this type of case was the case of a child, Doris H., aged eight. The swelling had existed for two months. Pain was not a feature. The true condition had been clearly overlooked. There were no stigmata of congenital syphilis. The family history gave no assistance. There was no evidence of interstitial keratitis, but the Wassermann was strongly positive. The swelling subsided after the exhibition of mercury and iodide. Personally, I do not think this type of case is common, unless I am constantly falling into the very error I wish to avoid.

Hæmophilia.—In this condition there is a sudden effusion into one or more joints, occurring spontaneously or as the result of a trivial injury. The more rapid the effusion the more painful the condition. A certain degree of pyrexia may be present. The joint most commonly involved is the knee-joint, but the ankle, hip, shoulder and elbow may also suffer. Occasionally there are pains in the limbs and no joint swelling. The disease rarely manifests itself for the first time under one year. Some manifestation is rarely delayed until after puberty. If the family tendency is known the diagnosis is not difficult. When the family history cannot be elicited a co-existing purpuric eruption or bleeding from mucous membranes may point the way to a correct interpretation of an anomalous joint swelling. Considerable difficulty arises where a pleural effusion or pericardial lesion co-exists with the joint affection.

Charcot's joint.—I have never seen a Charcot's joint in a child. The youngest patient I have seen with a joint of this nature was a youth, aged 16 (*a*): he sought advice for swelling of the right knee-joint and difficulty with his walking. He looked very delicate. The joint was much swollen and partial subluxation was present. It presented the features typical of the hypertrophic type of the malady: partial subluxation, soft crepitus, and hypertrophied synovial folds with loss of normal outline. The right ankle-joint presented a very similar appearance. The affection was quite painless. The knee-jerks were absent. The pupils were sluggish in their reaction to light, and there was distinct blunting to pin-point up to the knees. There was no evidence of syringomyelia.

Gout.—If this condition is borne in mind it can hardly give rise to difficulty in diagnosis, and I will content myself by quoting a statement made by the late Sir William Roberts: "Where there is a strong hereditary tendency the onset is often earlier—young men and even boys at school may undergo typical joint attacks." (*b*)

(*a*) Sir William Roberts and Sir John Rose Bradford, "Allbutt's System of Medicine," vol. iii., p. 124.

Late rickets.—The bony changes resemble those seen in rickets when it occurs at the usual age. The age of onset of this rare condition is between three and ten years. Though the skeletal changes are similar, it is interesting to note that dietetic treatment is of little avail.

In this brief survey of some of the conditions which, I think, we may possibly confound with syphilitic bone and joint disease, I have made no mention of lesions of the cranial bones. I hope members will give us their opinion as to the value of cranio-tabes, Parrot's nodes, from the diagnostic point of view.

I have made no mention of osteogenesis imperfecta, osteopsathyrosis, or mollities ossium. Is there any evidence, recently accumulated, to show that syphilis bears any relation to this condition?

If time permits I should like to hear what importance members attach to the presence of enlarged epitrochlear glands, (*a*) Moon's molars, and blue sclerotics, (*b*) enlarged spleen and persistent laryngitis.

DIVERTICULA OF THE LARGE INTESTINE. (*c*)

By R. W. MURRAY, F.R.C.S.,
Surgeon, Northern Hospital, Liverpool.

The clinical manifestations of diverticula of the large bowel are by no means fully appreciated by surgeons, and are practically unknown to the majority of the members of the profession engaged in general practice. Though isolated cases of this nature have been observed and reported upon during the past fifty years, it is only during the last few years that attention has been especially directed to this subject.

This has been done chiefly by Dr. Maxwell Tilling, of Leeds, who published a most interesting and practical paper on "Acquired Diverticula of the Sigmoid" in the *Lancet* of March 21st, 1908. The following remarks are based upon Dr. Tilling's observations, whose original paper should be studied by anyone interested in the subject.

During the last few years several cases of so-called "diverticulitis" have been under my care, and a week ago a case presented itself under the following circumstances:—

A man, 67 years of age, who had never suffered previously from any abdominal illness, was suddenly seized with acute pain in the abdomen. The attack occurred in an outside water-closet, and was so severe that he had difficulty in crossing the yard to the house. His wife and daughter assisted him upstairs to bed. The pain increased in severity, and was accompanied by vomiting.

On the third day of his illness he was admitted to hospital under my care. When I saw him he looked very ill, and by his bedside was a porringer containing dark offensive fluid he had vomited. He complained greatly of pain over the lower abdomen, which was slightly distended and very tender. The tenderness was not more marked on one side than the other. His temperature was 101, and his pulse-rate 124. His bowels had been opened freely the day before his admission.

There could be no doubt that the man was suffering from perforative peritonitis, but there was nothing in the story of his illness to indicate what viscus had given way. An operation offered him the only chance he had of recovery; and as the odds were strongly in favour of the vermiform appendix being the viscus at fault, I opened the abdomen in that area. A considerable quantity of brown offensive fluid escaped; the appendix was not felt, and no search made for it. A large drain was inserted, and the man taken back to bed.

He died the following evening. At the autopsy there was general peritonitis due to a perforation of a gangrenous diverticulum of the large bowel. In the pelvic colon were numerous diverticula, some very small, others large enough to project an appreciable distance from the wall of the gut. It was one of these large diverticula that had perforated. On opening the colon it was seen to contain numerous fæcal masses like rabbit "droppings." The small diverticula were for the most part empty, but all the large ones contained fæces. Corresponding to the level where the perforation had occurred, there was considerable thickening of the bowel wall, causing a marked constriction. There was no ulceration of the mucous surface.

My object in relating this case is to draw attention to a complaint which has certainly not received the attention it deserves. I am sure it is far more common than is generally supposed, and may present itself in various clinical aspects. Perhaps the most common form is as a stricture of the large bowel, which in many cases has been regarded as malignant. Since attention has been directed to this subject many museum specimens labelled "carcinoma of the sigmoid" have on microscopical examination proved to be inflammatory and of diverticular origin. This is a matter of great importance, and I wish to make a suggestion that I believe may be of assistance in arriving at a correct clinical diagnosis.

In the case I have related, and also in a case I saw some years ago, when the colon was opened it was seen to contain numerous fæcal masses like rabbit "droppings." These fæcal balls are undoubtedly formed in the small diverticula, which have a relatively large mouth and are covered by muscular fibres sufficiently powerful to enable them to expel their contents into the lumen of the bowel.

The point I wish to make is this: if in a case of obstruction of the large bowel fæcal masses like rabbit "droppings" are passed, the stricture is of an inflammatory nature and not cancerous. To put it in another way: what blood in the motions is to a malignant growth, these fæcal balls are to an inflammatory mass due to diverticula.

The larger diverticula cannot expel their contents because the stretched muscular fibres are replaced by fibrous tissue, and also because the mouths of these diverticula are so relatively small. Subsequent inflammation, due to the presence of imprisoned fæcal masses or concretions, may give rise to symptoms closely resembling left-sided appendicitis, or one of them may perforate as in the case I have related.

As to the ætiology of these diverticula, they must be either congenital or acquired. They may occur in the large or small bowel; and as they are met with most commonly in elderly persons in the region of the sigmoid, they are usually believed to be acquired. Old age and constipation are said to be the chief causes; but old age and constipation are much more common than diverticula. Again, many of the patients have not suffered from constipation, and several of them have not been old. The youngest recorded case occurred in a female, 22 years years of age. Comparative anatomy does not throw any light upon the subject, so far as I can ascertain, for similar diverticula are not normally present in the bowel of any animal. I believe that the primary factor is almost certainly some congenital defect in the structure of the intestinal wall. The probable reason why diverticula of the large bowel

(*c*) *Liverpool Medico Chirurgical Journal*, January, 1913.

have not been observed in young persons is because they give rise to no symptoms apart from inflammatory trouble in connection with their contents, and also because they have never been looked for.

The points I wish especially to emphasise are :—

(1) That left-sided appendicitis in elderly persons is probably due to an inflamed diverticulum.

(2) That perforative peritonitis in elderly persons may be due to the same cause.

(3) That if masses like rabbit "droppings" are found mixed with the fæces, it is a clear indication that there are diverticula present in the large bowel.

THE VALUE OF "OMNOPON" AS A GENERAL SEDATIVE. (a)

By C. L. WILLIAMSON, M.R.C.S.Eng., L.R.C.P. Lond.,

AND

G. W. N. JOSEPH, M.D., B.Ch., D.P.H. Liverpool,

Assistant Medical Officers.

Opium (writes Trotain, of Paris) is one of the most important drugs which our therapeutic arsenal possesses. The variety of its properties, its efficacy, its rapidity of action, all explain its importance and popularity. But opium has its faults ; for there is not one, but many opiums. Furthermore, its insolubility and the impossibility of administering it subcutaneously constitute a serious objection to its use ; in many cases, it is true, one can substitute the soluble hydrochloride of morphine for insoluble opium. But, if morphia possesses most of the qualities and defects of opium, it still differs from it in several points. Morphia has the disadvantage of being more depressant, more drastic in its action, more toxic, and having a greater disposition to cause intolerance.

It is therefore obvious that it would be to our advantage to possess a drug which would be a definite combination of all the alkaloids of opium, which would have all its beneficial properties and none of its disadvantages, which would be soluble, injectable, better tolerated by the human organism and less predisposing to a craving of habit (Trotain, "Contributions de l'Etude Thérapeutique de l'Opium et des ses Nouvelles Preparations").

This combination seems to have been successfully effected by Dr. Schaerges, chemist of the Hoffman-La Roche Company, acting on suggestions from Professor Sahli, of Berne, as a result of the latter's experiments with the alkaloids of crude opium in the early part of 1909. (b) To the drug the name of "Pantopon" was given, and as such it is known on the Continent and in America, whilst in Great Britain the name "Omnopon" was substituted.

The product is a crystalline powder of light yellow colour, readily soluble in cold water, less readily in alcohol, and only giving a weak acid reaction with litmus paper,

Before proceeding further with the clinical aspect of omnopon it would perhaps be interesting to make some reference to the composition of opium.

The average specimen of opium yields the following percentage of alkaloids :—

Morphine	10%—12%
Codeine	·3%— .6%
Anarcotine or Narcotine ..	7%
Papaverine	1%
Thebaine	.15%— .3%
Narceine	.02%

But, as already mentioned in the extract from Trotain's paper, samples of opium vary widely in the amounts of their alkaloids, the Smyrna and Constantinople drug being the nearest approach to "Official Opium," whilst that of Egypt and Persia is of an inferior quality.

In determining the value of opium the morphia content is the only factor which is usually considered. It is interesting to note, however, that apart from the alkaloids above mentioned at least fourteen other bases have been isolated, namely :—

Hydrocotarnine ..	$C_{12}H_{15}NO_3$	Hesse	
Codamine	$C_{20}H_{25}NO_4$	Hesse	1870
Laudanine	$C_{20}H_{25}NO_4$	Hesse	1870
Laudanidine ..	$C_{20}H_{25}NO_4$	Hesse	1894
Laudanosine ..	$C_{21}H_{27}NO_4$	Hesse	1871
Meconidine ..	$C_{21}H_{23}NO_4$	Hesse	1870
Papaveramine ..	$C_{21}H_{21}NO_3$	Hesse	1886
Protopine	$C_{20}H_{17}NO_5$	Hesse	1870
Lanthopine.. ..	$C_{23}H_{25}NO_4$	Hesse	1870
Cryptopine ..	$C_{21}H_{23}NO_5$	Smith	1857
Gnoscopine ..	$C_{22}H_{23}NO_7$	Smith	1878
Oxynarcotine ..	$C_{22}H_{23}NO_3$	Smith	1878
Xanthaline ..	$C_{37}H_{36}N_2O_3$	Smith	
Tritopine	$C_{42}H_{54}N_2O_7$	Kauder	1890

In addition to these there is a series of indifferent crystalline substances, such as meconin, meconoidin and opionin, which are present only in very small proportions.

In omnopon the alkaloids of opium are presented in the form of soluble hydrochlorides, while extractive matter and all inert bodies are eliminated.

The equivalents of omnopon are as follows :—

$$1 \text{ gr. omnopon} = \begin{cases} 5 \text{ grs. opium.} \\ 75 \text{ m. tinct. opii, B.P.} \\ 2\frac{1}{2} \text{ grs. ext. opii, B.P.} \end{cases}$$

Dosage and Mode of Use.—Omnopon is supplied to the medical profession in the followng forms :—

(*a*) A sterile 2 per cent. solution in ampoules containing 1.1 c.c. There is $\frac{1}{3}$ gr. of omnopon in 1 c.c. of this solution.

(*b*) Tablets of gr. $\frac{1}{6}$ which are readily soluble in a little cold water and act more rapidly if prescribed in that manner.

(*c*) Powder. This can be made up in a 2 per cent. solution, and can be kept for use for some time with the addition of 5 per cent. to 10 per cent. of alcohol.

(*d*) In ampoules with scopolamine, for use prior to the induction of anæsthesia for operation. These ampoules each contain omnopon .04 grm. and scopolamine .0004 grm. The contents of one is injected about two hours prior to operation.

It has been our custom to give doses ranging from gr. $^1/_{12}$—gr. $\frac{1}{3}$, but necessarily one must be guided by the requirements of each individual case. We never exceed gr. $\frac{1}{3}$ for a single dose, and have generally found that amount to be quite sufficient. For urgent symptoms we use the hypodermic ampoules and find the action extremely rapid.

Gr. 1 of omnopon is equivalent to m. 75 of tinct. opii (B.P.) and thus our maximum dose corresponds to m. xxv. of the official tincture.

Indications for Use.—Exactly the same as those calling for the employment of morphia or opium.

Clinical Use of Omnopon.—As our experience with omnopon is derived from observations of over 500 cases of all kinds, we think it might be of interest to mention, with details, some types of disease in which we found it beneficial. Furthermore we should explain at the onset that all our earlier cases received omnopon only after other drugs had been tried.

I.

Pulmonary Tuberculosis.—Over 200 cases of phthisis in our wards have received omnopon at various times and for various symptoms. The outstanding feature of the drug in this complaint is its power of relieving cough. Formerly our cases received glycoheroin, linctus simplex containing tinct. camph. co. m. xx. per dose, linctus opiatus, syr. codeinæ, heroin, and frequently all were useless. We then resorted to omnopon and with gratifying results. The purposeless, irritating, dry cough rapidly yielded to gr 1-6 4 hours, or when required.

(*a*) With cases under the care of Dr. Nathan Raw at the Mill Road Infirmary, Liverpool.

(*b*) Sahli, *Munchener Medizinische Wochenschrift*, No. 26, 1909; *Therapeutische Monatshefte*, No. 1, 1909.

In advanced pulmonary tuberculosis, probably more than in earlier lesions, is the extreme value of omnopon shown. It relieves the cough, the patient gets a thorough rest all night, wakes up comparatively fresh the next day, does not complain of headache or nausea. The drug does not affect the appetite, as morphia does, and as the patient becomes more comfortable he is able frequently to take more food. In several cases there has been a marked diminution of the night-sweats in patients getting omnopon regularly.

We have, in addition, found omnopon very successful in the treatment of other phthisical symptoms, such as dry pleurisy, diarrhœa, and insomnia.

Cases of hæmoptysis received a hypodermic injection of gr. $\frac{1}{3}$, and it is quite as successful in controlling hæmorrhage and calming the patient as larger dose of morphia. The following are the notes of three typical cases :—

Case 1.—J. J.,male, æt. 37, advanced ph. Admitted March 30th, 1911. Very troublesome cough ; keeping patient awake at night. Poor appetite. Was ordered, at different times, syr. codeinæ 1 dr. 4 hours, glyco-heroin 1dr 4 hours ; liq. morphinæ hydrochlor. m. xxx. 4 hours, during night, and a mixture containing acid hydrocyanici dil. and tinct. opii daily. All these had little effect. On May 17th, 1911, received gr. $\frac{1}{3}$ omnopon at night. Next morning the patient felt much better and said that he had had a splendid night.

Case 2.—William B., æt. 57. Admitted May 3rd, 1911. Suffering from phthisis with paroxysmal dyspnœa and distressing cough. Spt. ammon. aromat., ammon. carb. and pot. iodide, codeine, and finally morphia and opium, all failed to relieve to any great extent. On May 12th, 1911, received at night a subcutaneous injection of gr. $\frac{1}{3}$ omnopon about 8 p.m. Went to sleep at 9.45 p.m. and slept well for 3 hours. Woke up coughing, but slept for another three hours after receiving syr. codeinæ 1 dr. Woke up fairly fresh and with no headache. This night was characterised by a sound sleep and absence of dyspnœa, from which latter he almost invariably suffered in the early morning.

Since that date he has had occasional attacks of nocturnal dyspnœa, which never failed to yield to gr. $\frac{1}{3}$ of omnopon, and the patient is quite enthusiastic with the speedy relief afforded.

Case 3.—Mary C., admitted with advanced phthisis. Complains of marked dyspnœa—troublesome cough and sleeplessness.

For six consecutive nights was given a subcutaneous injection of omnopon gr. $\frac{1}{3}$. On each occasion she had a good night, slept well, cough much less, and altogether felt marked relief. There were no after-effects such as headache or nausea.

II.

Cancer.—We have treated, up to date, 40 cases of inoperable cancer with " omnopon " comprising, in their order of frequency, growths of uterus, rectum, breast, intestine, stomach, mouth and lung.

In this disease the action of omnopon is quite as constant as in phthisis. Some of our patients have received doses of gr. $\frac{1}{3}$ only when the pain is paroxysmal, but others, where constant pain has been complained of, have taken gr. $\frac{1}{6}$ 4 hours, for weeks at a time. We noted that, as in phthisis, the appetite is but little affected, the bowels remain regular, pain is relieved, the cases sleep better and longer, and existence is rendered as tolerable as possible in this distressing disease.

Type of Case.—B. P., æt. 51. Admitted on May 10th, 1911, with advanced carcinoma cervicis uteri. Complained of constant abdominal pain and restlessness. Was ordered omnopon gr. $^1/_{10}$ hourly until the pain was relieved. Received three doses and slept for four consecutive hours. At 10 p.m. again complained of pain and had another gr. $^1/_{10}$. Pain left her and she slept until 4 a.m. the following morning—May 11th, 1911. On May 17th, 1911, although the omnopon had been discontinued on the 11th, she had had no further pain and felt much better. No headache, nausea or subsequent constipation.

III.

The third class of cases is composed of those diseases where chief symptoms are pain, diarrhœa and vomiting of whatever nature. Here again we have found omnopon of great value as an adjunct to the recognised methods of treatment. The harassing pain of gastric ulcer and carcinoma soon yields to omnopon in repeated gr. $\frac{1}{6}$ doses, or occasional gr. $\frac{1}{3}$ doses by mouth as required.

" Omnopon," in several of our cases, has checked persistent vomiting when bismuth alone or in combination with liq. morphinæ hyd. or tinct. opii has failed. It has, moreover, the additional advantage over morphia of not predisposing to subsequent retching. Döblin in a paper on " Pantopon " (omnopon) states that one of his reasons for preferring the pantopon to morphia is the dispositon of the latter to cause vomiting and nausea. This tendency he finds practically nil after pantopon. (*a*)

In diarrhœa and intestinal catarrh, omnopon reduces the congestion and lessens peristalsis. In the persistent diarrhœa of advanced phthisis, we have frequently found it to act quickly and successfully when repeated doses of morphia have had little or no effect. Our custom has been to give it, for this type of case, after the patient has fasted absolutely for three to four hours.

In addition to the above it might be of interest to mention that two cases of hyperemesis gravidarum yielded to omnopon after bromides, bismuth, chloretone, oxalate of cerium and morphia had been tried unsuccessfully.

We quote one case to illustrate this class :—

Mrs. B.—Gastric ulcer and hæmatemesis. May 16th, 1911, severe epigastric pain and vomiting. Had omnopon gr. $\frac{1}{6}$ by mouth. Had a fair night ; did not sleep particularly well, but had relief from pain for some hours. Patient stated that relief was more marked than that afforded by the mixture she had previously been taking, viz., bismuth subnit. gr. x. and liq. morphinæ hyd. m xx.—4 hours.

IV

In cardiac lesions with precordial pain, angina palpitation and dyspnœa, we consider omnopon of the greatest value, and the speedy relief at times afforded is little short of wonderful.

V.

Omnopon, with advantage, can be utilised in the first stage of labour. It eases the severity of the pains without in any way diminishing the force or duration of the uterine contractions. Therefore we have a means of relieving, without unduly protracting, the long primary stage in the primipara.

VI.

The dyspnœic attacks of bronchial asthma rapidly subside when treated by a subcutaneous injection of gr. $\frac{1}{4}$ omnopon. One of our own cases, who was invariably relieved by the subcutaneous injection of adrenalin m.v. of a 1-1,000 solution, expressed a decided preference for omnopon " as it acted more quickly." In asthma it acts almost as well, when given orally, as subcutaneously.

VII.

Surgical Indications for Omnopon.—We regard post-operative conditions as offering a wide field for the use of omnopon. Under this heading we propose to describe our experience with omnopon-scopolamine adminstered before operation. Our cases were all adults and received one ampoule, containing omnopon 0.04 grm. with scopolamine 0.0004 grm., injected subcutaneously about 2 hours before operation. The anæsthetic in all cases was an equal mixture of chloroform and ether, with the occasional substitution of open ether. We noted, that in all save two instances there was an absence or diminution of the stage of excitation ; the breathing,

---

(*a*) *Therapeutische Monatshefte*, April, 1911.

when anæsthesia was complete, was regular and rather slow, as was the pulse. Moreover, it was found that the smaller amount of anæsthetic than usual was needed to keep the patient under; there was absence of salivaton when open ether was substituted for the C.E. mixture. As mentioned above two of our cases were exceptions, there being a prolonged stage of violent excitation and struggling; during the operation the anæsthetic had to be freely pushed. Both these cases were definite "alcoholics."

For a fuller description of omnopon in anæsthetic and surgical work we would refer the reader to the admirable articles of Gray (*a*) of Aberdeen, and Leipoldt. (*b*)

A striking feature of these cases was the excellent condition of the patient after operation. In our cases there was invariably absence of post-anæsthetic retching or vomiting, the patient was drowsy or slept comfortably for a few hours, the pulse was regular and not rapid, and pain was either slight or not complained of at all.

Omnopon can with advantage be substituted for morphia in the post-operatic stage, since it has less tendency to constipate or produce nausea.

VIII.

In Continental literature several authors have recorded success to omnopon in the treatment of cases of morphiomania, and it may be of interest here to give details of a case we had in this institution.

H. A., æt. 45, marine engineer, admitted October 3rd, 1911, suffering from alcoholism.

He had been drinking heavily and was very weak on admission. It was noticed that both arms were covered with scars resulting from hypodermic injections, and on being questioned he confessed to having taken morphia for over two years, and said that without it he could not sleep.

During the first week he had omnopon gr. $\frac{1}{3}$ by mouth twice daily, without knowing the nature of its composition, and towards the end of this time said he was feeling so much better that he thought he could do without morphia altogether when he got outside again.

The patient was in hospital for six weeks, and during the last five weeks had no treatment other than simple tonics. Since his discharge, three months ago, he has reported himself to us, and is looking so well as to quite bear out his statement that he has had no recourse to the drug since his treatment in hospital.

The following is a list of the last 500 cases treated by us with omnopon, and shows the class of case in which it has been of service:—

Pulmonary tuberculosis	229
Carcinoma	40
Chronic bronchitis'''	30
Pain of fractures, etc.	26
Cardiac diseases	23
Tubercular peritonitis, etc.	18
Acute abdominal lesions	18
Gastro-enteritis	17
Confinements	15
Acute pneumonia (early stage) ..	15
Alcoholism, mania, etc.	12
Bronchial asthma	11
Chronic rheumatism	10
Pleurisy	8
Specific	7
Myelitis and paraplegia	5
Chronic nephritis	4
Locomotor ataxy	3
Diabetes	2
Splenic leucocythæmia	2
Hyperemesis gravidarum	2
Chorea gravis	1
Pruritus vulvæ	1
Cerebral tumour	1
	500

Summary and Conclusions.

In conclusion we should like to emphasise the following points:—

(1) In omnopon we possess a preparation of fixed and unvarying composition, containing the chlorides of the total alkaloids of opium in a form which is soluble in water.

(2) We especially wish to draw the attention of the general practitioner to its value in those cases of advanced pulmonary tuberculosis where palliative treatment alone is possible. In this class of sufferer with incessant cough, drenching night-sweats, sleepless nights, dissatisfied with his medicine and food and discontented with everything around him, omnopon comes as a great boon.

(3) Again this preparation is most serviceable in all those cases of malignant disease where pain has to be relieved and the attention of practitioners may be drawn to the fact that omnopon written as a prescription, does not convery, to a timid patient or his friends, the same impression as the name of opium or its official derivatives.

(4) In all classes of cases, where one is compelled to use morphia, one can with advantage, in our opinion, substitute omnopon. This latter does not cause the same amount of subsequent nausea or constipation, nor does it appear to affect the appetite. One other rather important point is the fact that the patient does not appear to become tolerant of its use, and thus there is no need for increasing the dose. We have, in that connection noted that patients whose condition has improved, made no objection to the drug being discontinued, rendering the fear of the formation of a drug habit less probable than in the case of morphia or opium.

(5) It can be used in cases of chronic renal insufficiency in gr. $\frac{1}{3}$ does for dyspnœa, and Trotian has recorded its successful use in a case of uræmic dyspnœa and also in the delirium caused by cardiorenal intoxication.

We wish to express our thanks to Dr. Nathan Raw for kind permission to publish these cases.

A NEW METHOD FOR THE TREATMENT OF BACTERIAL INFECTIONS (A MODIFICATION OF VACCINE TREATMENT). (*a*)

By PROF. N. F. SURVEYOR, M.D., M.A.Bombay, M.R.C.P.Lond., D.P.H.Cantab.
Professor of Bacteriology, Grant Medical College, Bombay.

Treatment of diseases with bacterial vaccines has acquired a definite position in medicine in the course of the last seven years, and it is not necessary to bring forth any facts in support of it at this stage; rather one must be cautious in falling into the opposite error of using vaccines for all diseases that human flesh is heir to. I have not yet heard of anyone recommending this treatment for a broken limb, but I have come across a case where a patient was at least under the impression that his ventral hernia (about the size of a cocoanut) would be cured if he underwent a course of vaccine treatment for ulceration of the skin over the sac.

Since my last communication on vaccine therapy (1) 526 cases, including cases of tuberculosis, have been treated by me on similar lines, and I beg leave to place before the meeting a short account of my observations.

In the paper mentioned above I had stated that the staphylococcic vaccines, whether stock or autogenous, did not always give satisfactory results in cases of pyæmia, and it was suggested there that this might be due to the fact that there was infection with more than one microbe. This is quite likely to be the case, especially so if the other microbe is a streptococcus which, being a slow grower, is, as it were, swamped by the staphylococci and thus destroyed in the culture tube. This actually happened in a case of diabetic

(*a*) Paper read before the International Medical Congress in London, August, 1913.

gangrenous abscess of the foot. On the first occasion, when the pus was removed before the skin had ruptured, a pure culture of streptococcus was obtained. About two days later another sample of pus gave a pure culture of staphylococcus, and the vaccine prepared from this was useless, so that the disease spread very rapidly, and in a fortnight's time the question of amputation above the knee-joint was seriously considered by the physicians and surgeons who saw the patient. Besides the staphylococcic vaccine a stock streptococcic vaccine was also injected by the bacteriologist in charge of the case, and anti-streptococcic serum was also used at the same time without any benefit. However, as soon as the vaccine of the patient's own streptococcus was combined with his own staphylococcic vaccine a change for the better wsa perceived, and the patient make a complete recovery (Case No. 365 of my series).

In another case (No. 444 of my series) of diabetic abscess of the foot, a very instructive fact was noticed. The infecting microbes were a very short bacillus (non-motile) and a fine streptococcus, and the case was progressing satisfactorily when small carbuncles, about a dozen in number, formed on the back, neck and shoulders, in spite of the vaccine treatment which the patient was regularly getting. However, on examining the pus from the carbuncles a pure culture of staphylococcus aureus was obtained, and vaccine prepared from this had the desired result. Thus the patients had three infecting microbes at one and the same time, and combined vaccine was required for a complete cure. Now in this case the third microbe was the infecting agent for another part of the body, but it is quite possible that the germ may have gained entrance to the already infected area—namely, the foot, and vaccine treatment would have failed to bring about a complete cure unless another bacteriological examination of the pus had been made. Thus in such cases it is always advisable to have the pus re-examined from time to time if the progress is not satisfactory. These two cases, several cases of pyæmia, and pyorrhœa alveolaris have been treated by a modified form of vaccine, and with very good results. These modified vaccines I have called "autotoxins" or "autoxins" to distinguish them from the ordinary bacterial vaccines. In some cases the bacterial vaccine is prepared not with normal saline solution as a diluent, but with autoxin. These vaccines are called autoxin-vaccines; and have been found to be most effective in the treatment of bacterial infections.

It is well known that one often comes across cases where the causative organism of any particular lesion cannot be grown on any of the known media, thus making the preparation of a vaccine impossible. One such case I have come across (Case No. 45 of my series) where the patient was subject to subcutaneous abscesses of the type generally known as blind boils, which would come on, three or four at a time, at frequent intervals throughout the year. Repeated examinations of the pus failed to show any organisms in smears or in cultures. In a fresh preparation, cells with a certain amount of limited amœboid movement could be seen, but these proved to be leucocytes. Major Liston, Director of the Bombay Bacteriological Laboratory, also saw the case with me, and subjected the pus to a thorough examination by cultural methods, for which my thanks are due to him. He corroborated my observations. Stock staphylococcic and streptococcic vaccines were used at first without any benefit, so it was resolved to try a method which I had been considering for a long time as quite feasible for bacterial infections. This method is comparable with the vaccine lymph inoculation used for protection against small-pox.

The method as adopted by me is to take a measured amunt of pus and to dilute it with varying amounts of normal saline, so as to getdefinite dilutions of the toxins present in the pus. In this particular case I diluted the pus 25 times and sterilised it at 60° C. for one hour, in order to kill any organism which may have got in either accidentally or may have been the cause of the pus formation, but which was incapable of being cultivated on ordinary media. This dilution was used for injections, and the result was that the patient stopped getting any more abscesses, and was free from her trouble for the first time after many years. The illness had commenced when the patient was eight years old, and, at the time when she had the injections she was about 25. As Calmette's ophthalmo test was positive in this case at the second trial, she was given one injection of tuberculin in conjunction with "autoxin," but the effect of the "autoxin" when given alone was so marked in checking the appearance of the boils and aborting those that had already appeared, that the injections of the latter alone were persisted in with the most gratifying results. Besides this, the roughened character of the skin and low fever also disappeared under these injections, and the patient put on weight. The pus was injected into a rabbit and guinea-pig to see if any tubercular infection was present, but the result was negative. The positive ophthalmo reaction in this case meant that there must have been a small latent tubercular focus in the body, and I do not see any reason to attribute the boils to tubercle.

This method has been extended to other cases also, from which definite organisms could be developed, and some very good results have been attained. The method was found to be particularly applicable to certain cases that showed a large number of various organisms in smears of pus obtained with all bacteriological precautions, none of which, however, could be made to grow in the test-tube. The material in such cases was mostly foul smelling, although taken from unopened abscesses. The only explanation that I can offer is that the organisms were so devitalised that they were incapable of growing on artificial media. This was specially noticed in a rectal abscess, a scrotal abscess, and also in a case of abscess on the hard palate due to carious teeth. In the second of these cases a coliform organism was obtained in culture after great difficulty, and in the third a fine streptococcus was grown, while pus from the rectal abscess remained sterile, although in all these cases large numbers of diplococci, bacilli, and staphylococci were seen in smears from the original pus, which was extremely foul-smelling. In another similar case of abscess of the scalp no culture whatever could be obtained. In such cases this method has been found very successful. In all cases, wherever the pus can be obtained in a fair amount (at least 1.25 c.c.), this method had been used for preparing the "autoxin."

Strength of Autoxin.—Various dilutions of the pus (from 1 in 10 to 1 in 600) have been tried, and it was found that a dilution of 1 in 50 is suitable for most cases of staphylococcic infection and 1 in 100 for streptococcic infection. In cases of pyorrhœa alveolaris, greater dilutions (1 in 300 to 1 in 600) seem to answer better. Counting the number of bacteria injected for the purpose of standardisation, as is done in the case of ordinary vaccines, is not applicable here, as the disintegrated corpuscles and other débris interfere with the counting process; nor is this necessary. The strength of the "autoxin" can be fairly definitely adjusted by the amount of dilution used.

Class of Cases in which "Autoxins" are Useful.—Amongst the cases suitable for this mode of treatment may be mentioned cases of pyæmia, septicæmia, and the similar diseases, where there is no time to be lost. One of the greatest advantages of this method is that the first injection can be given within 18 hours after obtaining the material. This method is useful in another class of cases—*i.e.*, where a variety of organisms is present in a given sample of pus, so that it is very difficult to isolate the different kinds of bacteria and prepare a vaccine from each. In such cases at best a vaccine can be prepared from a mixed culture, and the relative proportion of each variety of microbe cannot be the same in the vaccine as that present in the *materies morbi*, on account of the varying rates of growth of the different organisms in the cultural media. Again, in the class of cases under consideration, it is often difficult, if not impossible, to fix upon any particular germ as the cause of the trouble, and more often than not the treatment of such a case is only a shot in the dark, when one uses a so-called predominant microbic vaccine.

Several cases of chronic bronchitis and of pyorrhœa alveolaris, four cases of gonorrhœal synovitis (in three of which the synovial fluid was sterile), two cases of mucous colitis, and one of cystitis, have been treated by this method with marked benefit. One hundred and one cases have been treated by this method with very good results, and without any severe reaction or untoward effect. A further improvement of this method as stated above is to use the "autoxin" instead of the normal saline for the preparation of a vaccine.

As stated above, pyæmia cases, from which Staphylococcus aureus is ordinarily isolated, did not respond satisfactorily even to auto-vaccine treatment. In such cases of injection of "autoxin" and "autoxin-vaccine" has given very satisfactory results (as in Cases Nos. 465 and 444 mentioned above, both of which had had vaccine treatment prior to the use of the autoxin-vaccine).

One case of chronic bronchitis with asthma has been treated by me with marked benefit by this method. The patient, whose original weight in good health was 141 lb. was found to weigh only 95 lb. when this treatment was adopted, although she was living in comfortable surroundings. The sputum did not show any tubercle bacilli. However, there were frequent attacks of slight hæmoptysis, and as the ophthalmo test was found positive, tuberculin treatment was given first. Although some benefit was noticed, there was a slight further loss of weight, and the relief from a harassing cough was only slight. An "autoxin" of the sputum, 1 in 50 dilution, was therefore given. The dose was 0.5 c.c. to begin with, and the largest dose given was 1.3 c.c. There was marked improvement noticed in general health, and in the beginning of the present year her weight was 126 lb., when she left Bombay for her home in Northern India. In all she had ten injections of this preparation. These were given at intervals of 15 days to one month, *i.e.*, on lines similar to those followed for vaccine treatment.

A case of pernicious malaria with a very large number of crescents in the blood was treated by a somewhat similar method, and as a sequence very rapid disappearance of the crescents occurred. Blood (6 c.c.) was removed from a vein, diluted with 100 c.c. of normal saline, and hæmolysed by addition of 5 drops of sodium hydrate (15 per cent. solution). With Thoma Zeiss hæmocytometer apparatus the crescents were counted in the diluted blood before the addition of sodium hydrate. The number of crescents present per c.c. of the diluted blood was 140,000. After addition of the sodium hydrate, the flask was left in the incubator for 24 hours and tested for sterility. The crescents in the patient's blood disappeared rapidly, *i.e.*, in 22 days. He had the largest number of crescents I have ever come across. Considering that crescents generally disappear in about two months in ordinary cases, this period appears to have been considerably shortened by this method. (2) In this case when the crescents were first counted, as compared with 100 leucocytes they were 112; and in one drop about 8 m.m. in diameter the number was 13,068. The dose given to start with was 1 c.c. and the fifth and last dose was 4.5 c.c. In another case with a huge spleen after five injections, although no reduction of the spleen was noticed, the patient's weight and general condition were much improved. Unfortunately the treatment could not be followed further.

As regards the treatment of pyorrhœa alveolaris with autoxin-vaccine some remarks are necessary here. The usual method adopted in the vaccine treatment of this disease is to isolate what is considered to be the predominating microbe, usually a streptococcus or a bacillus, and to make the vaccine from that organism. This method does not give very satisfactory results as regards the formation of pus, but amelioration of the other physical symptoms has been obtained. This result is to be expected considering that the micro-organisms are situated in the pockets between the gums and the teeth, and the antibodies are not likely to reach them in sufficient amount to cause their complete destruction. In fact, these organisms are extra corporeal, like the Bacillus coli is in the alimentary canal, and as any attempt to destroy the latter by vaccine treatment is likely to be of no avail, the same holds true for vaccine treatment of pyorrhœa alveolaris. The physical symptoms can only be relieved in so far as they are due to the microbes that have attacked the tissues. Those in other positions cannot be destroyed by vaccine treatment. The pockets in pyorrhœa must be cleansed with antiseptic washes at the same time that vaccine treatment is used. Again, in cases of this disease the number of varieties of microbes present renders the problem of vaccine treatment for this complaint one of considerable complication. Besides streptococcus and staphylococcus one meets with different varieties of bacilli including B. fusiformis and also spirochætes of various sorts. As if these were not enough, there are often seen in such pus, crowds of infusoria (Trichomonas buccalis) and amœboid organisms. However, on attempting to obtain a culture, one generally isolates a streptococcus or sometimes a bacillus, while the bulk of the organisms, especially the spirochætes and infusoria, cannot be cultivated on ordinary media. Now, the toxic symptoms in a case of pyorrhœa alveolaris are not only to be attributed to one variety of the organism which is capable of being isolated and used for vaccine, the other organisms must have some share in the production of the physical signs and symptoms which one notices in such cases. So it is not to be wondered at that very few cases of pyorrhœa alveolaris can get benefit by simple vaccine treatment only. In the autoxin-vaccine treatment of this disease the pus is sucked up from the gums by a double-bulb sterile pipette whose distal end is sealed, and the bulb, near this end, having been made red hot exerts suction on getting cold, the proximal open end of the tube having been introduced into the purulent pocket. The gum bleeds freely when this is done, and some blood also enters the pipette. When a sufficient quantity is obtained the open end is sealed off and the pipette is put into the incubator for about 24 hours. This ensures a further growth of the germs in the patient's own blood. Next day the whole quantity, the blood, pus, etc., is measured and diluted with normal saline in the proportion of about 1 in 300 to 1 in 600 parts, and sterilised at 60° C. Before sterilising these autoxins it is generally advisable to add 1 to 5 drops of caustic soda solution (15 per cent.); this breaks up the blood clot, and the pus cells. When the material is of a very tenacious consistency it is advisable to add the soda before the dilution, so that the caustic may act in a more concentrated form, and the mixture thus made may be left in the incubator for 18 to 24 hours; after this time the dilution and sterilisation can be proceeded with. To this autoxin, the streptococcus isolated from the original material may be added, and the autoxin-vaccine thus prepared. This preparation I have found much more efficacious in relieving the physical symptoms than ordinary vaccines. Thus in a former series of observations on cases of this disease treated by vaccines, only 4 out of 21 cases were relieved of their physical symptoms, while since the use of autoxin-vaccine method of treatment, out of a series of 17 cases only 2 failed to respond to the treatment, and both these were cases of very severe diabetes, the urine showing the presence of not only sugar, but also of acetone and diacetic acid in large amount.

In cases of mucous colitis most marked benefit was noticed by the use of autoxin injections.

The first case (No. 412 of my series) has been under surgical treatment for abdominal pains. The abdomen was opened thrice for one reason or other. However, the pains recurred after recovery, and large quantities of mucus either mixed with or free from fæcal matter were passed daily. Mucus free from fæcal matter was generally passed about half an hour after a boric enema, which the patient was in the habit of taking daily as a bowel wash. Such mucus was received in a sterile Petrie's plate, and autoxin prepared from it. The mucus was free from any fæcal contamination or odour, and this was diluted to the extent of 1 in 25. The first injection produced increased mucus, so the dilution was increased to 1 in 300. Five injections of this weaker autoxin were given at intervals of 15 days, and after that the patient's condition was much better and no more mucus was passed separately. At last—an injection of 1 in 25 dilution—was given, and the patient went away to her native country much relieved of all her symptoms, except those due to ventral hernia which had developed subsequently to the first operation.

An attempt to isolate a microbe from this mucus proved futile, as there were several organisms with the bacillus coli.

The second case (No. 468 of my series) was not so severe and not of long standing. The first case had a history of about 4 years' illness, while in this case the period was only 6 months. There was a history of chronic diarrhœa alternating with obstinate constipation. Olive oil and salol injections per rectum were tried, together with administration of the same oil per os. The diarrhœa and constipation were relieved hy this method, but at the end of 5 months' treatment the passage of mucus was just as bad as when the patient first came to me. As the mucus was partially mixed with fæcal matter, it was decided to try the autoxin prepared from the first case. In all five injections were given (1 in 25), the dose varying from 0.5 c.c. to 1.7 c.c., and the mucus stopped completely. Six months after the last injection the patient returned, saying that, on account of some indiscretion in diet he had an attack of diarrhœa, but the mucus had not reappeared even at that date, and a simple bismuth powder preceded by a dose of castor oil put him right. Observations with tuberculous pus and phthisical sputum, containing tubercle bacilli, are being carried on, but as these are not sufficiently advanced for forming a definite opinion about them I do not record them here. Recently a paper was published in the *Lancet* (August 24th, 1912) on the treatment of tubercular glands with an extract made of similar materials by Drs. Fraser and McGowan. As regards chronic bronchitis a paper was published recently by Dr. Gillett in the *British Medical Journal* (February 22nd, 1913). He uses the mixed culture from the expectoration for treatment of such cases. He also obtained good results. It seems, therefore, that the method described by me deserves to be given a trial wherever possible.

Table showing the Relative Value of Vaccine Injections as compared with Autoxin and Autoxin-Vaccines.

	Autoxin.		*Autoxin-vaccine.*		*Vaccine.*	
Total cases treated	101		29		135	
Cases improved	77	76·2 %	26	90%	92	68·15%
Cases not improved	24	23·76%	3	10%	43	31·85%

Table showing the Effects of Autoxin (1 in 100 dilution) in cases of Acute Pneumonia [six of the Autoxin cases are not counted in the First Table].

Nature of Treatment.	*No. Cases.*	*Deaths.*	*Deaths %*	*Remarks.*
Ordinary treatment	41	26	63.4	Twelve of these cases died within 24 hours after admission.
Vaccine (stock). .	10	8	80	Very severe cases.
Autoxin . .	7	—	—	Very severe cases; one of these had endocarditis subsequent to pneumonia.
Autoxin (stock).. .	4	4	100	Very severe cases; autoxin from one of the cured cases used.

OPERATING THEATRES.

HAMPSTEAD HOSPITAL.

Gynæcological Operations by Mr. Jackson Clarke.

The following series of cases were operated upon by Mr. Jackson Clarke:—

Case 1.—Ovarian Cyst.—R. C., æt. 26. Admitted May 29th, 1911; discharged July 10th, 1911. History of pain in right side of abdomen and offensive vaginal discharge. *Operation.*—May 31st; C.E.—ether. Uterine cavity curetted. Nothing abnormal removed. Pain continued after operation. *Second operation.*—June 14th; C.E.—ether. A cystic right ovary and the appendix, which was bound down by a few old adhesions, were removed. No drainage. Wound healed by first intention. Uneventful recovery.

Case 2.—Fleshy Mole.—M. L., æt. 30. Admitted December 20th, 1911; discharged December 30th, 1911. Three weeks' history of uterine hæmorrhage. Thought to be 4½ months pregnant. Cervix soft. Internal os tightly closed. Hæmorrhage slight. Temperature, 99°; pulse, 76. *Operation.*—December 21st; C.E.—ether. Dilatation and curetting. Two months fœtus extracted and partially organised placental tissue. Good deal of hæmorrhage. Uneventful recovery.

Case 3.—T. B. Mesenteric Glands.—A. P., æt. 40. Admitted October 18th, 1911; discharged December 16th, 1911. Twelve months before admission aching and throbbing pain in epigastrium, generally after meals. Vomiting. Jaundiced. No hæmatemesis or melæna. Similar attacks six weeks later, and since then at intervals of a month or fortnight. Rapid loss of weight for four months. Feet used to swell on standing. A thin, jaundiced woman. Marked tenderness in epigastrium, around umbilicus and down left side of abdomen. A mass palpable to right of umbilicus. Spleen and liver not palpable. Aorta displaced to the left; pulsation much more marked than normal. Stomach not dilated. Temperature, 98°; pulse, 96. Urine, nil. Per rectum, a hard, tender mass palpable about three inches from the anus on the right side; fairly mobile. Sir John Broadbent transferred to surgical side. *Operation.*—November 8th; C.E.—ether. Incision over appendix region. A number of caseous and calcifying tuberculous glands removed from mesentery. No drainage. Abdominal incision healed by first intention. Eleven days after operation temperature rose to 100.6°. Pain and swelling in region of saphenous opening, pain in popliteal space, and some œdema over tibia. (Thrombosis.) Temperature gradually came down and became normal at the expiration of a fortnight. Other symptoms disappeared. General condition of patient much improved on discharge.

Case 4.—Myomata Uteri.—A. S., æt. 38. Admitted January 3rd, 1911; discharged February 7th, 1911. Six months' history of heavy, bearing-down feeling during defæcation and on exertion, frequent desire to micturate and lassitude on exertion. Two fairly mobile tumours palpable. Each one reaches to a level with the umbilicus and extends literally halfway across the abdomen from the mid-line, one being on either side. Both attached posteriorly. No abdominal tenderness. *P.V.*—No tenderness. Both tumours continuous with uterus, which was retroverted. *Operation.*—January 11th; C.E.—ether. Abdominal hysterectomy for multiple fibro-myomata. Uninterrupted recovery.

Case 5.—Myomata Uteri—Appendicitis.—K. L., æt. 38. Admitted December 16th, 1911; discharged January 12th, 1912. Pain in lower part of abdomen and hæmorrhage from vagina—two days. Pain on micturition—seven days. Last menstrual period ended three weeks ago, having lasted fourteen days. Previously catamenia always regular, lasting 4—5 days. No history of vaginal discharge. Temperature 101.8°; pulse, 104. *Vaginal examination.*—Body of uterus enlarged and tender. Distinct mobile tumour in right fornix; outlines indefinite. Abdomen markedly tender on right side and somewhat rigid. *Operation.*—December 18th; $CHCl_3$—ether. Appendix removed and found to contain concretions. Pus soon flooded the pelvis from the right tube. Subperitoneal

uterine fibroids. Uterus (body) and right tube and ovary removed. One tube. Uneventful recovery.

Case 6.—Intestinal Obstruction.—T.H., male, æt. 9. Admitted December 8th, 1911; discharged January 10th, 1912. Admitted with a 12 hours' history of continuous vomiting of brown matter. Unable to keep any food down. Bowels open once. In Hampstead Hospital two months ago for appendix abscess and general peritonitis—treated by drainage (five tubes) and abdominal irrigation. On admission temperature 98.6°; pulse, 104; respiration, 40. Decreased abdominal movement with respiration. Some general tenderness and distension. Face drawn. Tongue coated. Breath foul. *Operation.*—December 9th; CHCl —ether. On opening abdomen, small bowel distended and whole of colon collapsed. Intestines bound down in many places by bands of adhesions, especially in the region of the ileo-cæcal valve. All adhesions excised. No drainage. Two days after operation developed a right basal pneumonia. His chest was in a condition of fibroid phthisis on admission. Wound healed by first intention.

Case 7.—Twisted Ovarian Cyst.—K.T., æt. 34. Admitted December 5th, 1911; discharged December 30th, 1911.—Sent in as a case of acute appendix.—3 days' history of pain in r. iliac fossa and vomiting. Bowels open. Six months pregnant. *On examination.*—Definite hard swelling in appendix region with some tenderness. Temperature 99.6°; pulse 100. Rectal examination.—Nil. Vaginal examination.—Softened pregnant cervix. Presenting fœtal parts felt. *Operation.*—December 6th; C.E.—ether. Incision over appendix region. A large dull bluish ovarian cyst, which was lying external to the ascending colon, presented, and was excised. The pedicle was twisted. Uneventful recovery.

Case 8.—Bilateral Ovarian Cyst..—M.E., æt. 70. Admitted November 4th, 1911; discharged November 28th, 1911. Two years' history of abdominal pain and swelling. Chronic and persistent diarrhœa. No vomiting. No wasting. Three weeks' acute history. Menopause 20 years ago. *On examination.*—Temperature 99.2°; pulse 116. Large abdominal tumour on right side occupying entirely right iliac fossa, umbilical and hypochondriac regions. Immobile. Flat on percussion. Slight fluid thrill. Vaginal examination.—Uterus retroverted. Cervix atrophied. Marked bulging in right fornix. *Operation.*—November 8th. 1911; C.E.—ether. Median incision. A large and almost black unilobular ovarian cyst, occupying nearly half the abdomen and with a twisted pedicle, was removed on the right side. Whole mass was almost gangrenous. A small ovarian cyst on the left side was removed. No signs of malignant disease on bowel wall. No drainage. Uneventful recovery.

Case 9.—Endometritis.—M.P., æt. 37. Admitted October 24th, 1911; discharged November 27, 1911. History of recurrent vaginal hæmorrhage. Last attack four days ago. Legs slightly swollen. Urine—nil. Menorrhagia has been constant. Uterus was curetted on September 13th, 1911; nothing definite found. Since the curettage has suffered a good deal of pain in lower part of abdomen. *Operation.*—October 28th; C.E.—ether. Uterus curetted Pathological report: "Hyperplastic and interstitial endometritis. No evidence of malignancy." *After-result.*—Temperature chart normal.

Case 10.—Fæcal Obstruction.—E.G., æt. 13. Admitted October 21st, 1911; discharged November 1st, 1911. In-patient 13 months ago for tuberculous peritonitis. No operation. Admitted for "frequent bilious vomiting." Twenty-four hours' history of umbilical pain, vomiting, and no action of bowels. Bowels open before onset of pain. Patient looks ill. Complexion earthy in colour. Tongue, thick brown coat. Breath very foul, odour almost fæcal. Abdomen slightly distended, only slight movement and rather rigid. No visible peristalsis. Pain and tenderness around umbilicus. No glands or abnormal masses palpable. Rectum full of fæces. Good result from soap-and-water enema, which completely relieved pain three hours later. No operation. *Result.*—Cured.

AUSTRIA.

Vienna, Sept. 13th. 1913.

Inequality of the Pupils in Visceral Disease.

Dr. Anton Bukolt has just published his observations on an interesting clinical sign which has hitherto attracted comparatively little general notice: inequality of the pupils in cases of unilateral pulmonary disease. The occurrence of such inequality, although by no means consistent, and in some instances of its appearance quite transitory, is so far frequent as to give it a more decided claim to clinical attention than it has generally received, while its presence unquestionably suggests associations of great interest in the borderland which connects and separates physiology and pathology. In a series of 35 cases of uncomplicated unilateral pneumonia without any considerable involvement of the pleura, inequality of the pupils was present in 23—or in 65.7 per cent. of those in which it was specially looked for. The inequality presented consisted in 14 of the cases of mydriasis and in 9 of myosis on the side of the pulmonary affection. In 17 of the cases, the lower lobe of the left lung was affected; in 10 of these there was mydriasis on the same side as the pulmonary lesion; in two there was myosis; in the remaining five the pupils showed no difference. In a single case, in which the whole of the left lung was involved, there was observed a transitory mydriasis which lasted but a short time. In 9 cases of pneumonia of the right lower lobe, there was marked myosis on the same side in three; slight myosis on the affected side in a corresponding number; while the remaining three presented no difference in the size of the pupils. Of two cases of pneumonia of the right upper lobe, one presented mydriasis on the affected side; in the other the pupils were equal throughout. In a case of right-side pneumonia, which affected the upper and middle lobes, there was mydriasis on the affected side. In a case of right-side inflammation of the middle lobe there was no difference of pupils observable.

Careful research in the literature revealed scattered records of such varying pupillary differences in the course of pulmonary lesions; also in other thoracic and abdominal lesions, and even in some of the systemic fevers, and in general constitution cachexiæ. So far back as 1872 it was pointed out by Roque that a difference in the dimensions of the pupils was sometimes observable in unilateral lesions of various parts of the body, especially in unilateral pulmonary affections, acute and chronic, and in lesions of the bronchial and cervical lymphatic glands. The observations of Pasternatzky led him to the conclusion, in 1886, that inequality of the pupils occurred much more frequently in cases of visceral disease than was generally believed. This observer's researches led him to the conclusion that there existed even a proportion of incidence which approximated the constancy, although it seemed very unlikely that it could even attain it. Thus, a pupillary difference was observable in 85 per cent. of cases of pneumonia crouposa, in 61 per cent. of cases of aneurysm and cardiac debility; while it also ocurred with less frequency and regularity of proportion in cases of pleuritis, chronic catarrhal pneumonia, colica hepatica, colica renalis, etc. A difference of pupillary dimensions was also not infrequent in typhus, scorbutus, and other constitutional diseases, especially when visceral complications were present. Pasternatzky's own observations showed him that in croupous pneumonia there was at first a widening of the pupil of the affected side, to be followed by subsequent narrowing (in the third stage). On the other hand, the irregularity of the pupils which occurs in cases of cardiac debility, aortic aneurysm, etc., remains a constant and unchanging condition. Pasternatzky regarded all such cases of irregularity of pupils, unaccompanied by any other ocular manifestation, as a neural phenomenon produced by reflexion of the path of the peripheral stimulus on to the sympathetic system.

Fleischmann in 1876 recorded his observations of symptoms accurring in infants during the period of dentition, which could be explained only by reflex stimulation of the sympathetic: flushing or pallor of one side of the face and head; formation of localised and transitory patches of erythema on cheek or neck on one side; also intermittent neurosis of the sympathetic affecting the whole of one lateral half of the body: accompanied by redness and elevation of temperature all over the affected side; with redness and elevation of temperature of the ear of the same side—such as follows unilateral section of the sympathetic nerve-trunk. Seeligmüller, in 1877, described four cases of pulmonary lesion, each of which was accompanied by pupillary signs. His observations led him to believe that not only apicial pneumonia and pleuritis, but deep-seated pleuro-pneumonia, are sometimes productive of manifestations of engagement of the sympathetic. Rampoldi, in 1885, published two cases, of acute and chronic inflammation respectively of the apex of one lung in one of the cases, of both apices in the other. There was marked mydriasis, which he explained by reflex stimulation of the sympathetic, transmitted centrally by the pneumogastric, without excluding a possible genesis by direct pressure on the former. The same observer published in 1890 the case of a woman who had a tuberculous cavity in the right lung and a myotic pupil on the same side. The autopsy showed that a thickened pleura compressed the lower cervical ganglion of the sympathetic, which also displayed copious leucocytic infiltration. Destrée, in 1894 (International Medical Congress, Rome), stated that in 97 per cent. of all cases of pulmonary tuberculosis inequality of the pupils was present—dilatation of the pupil of the affected side. It was variable in amount, sometimes disappeared and returned, and was attributed by him to pressure of tuberculous bronchial glands of the sympathetic nerve-chain. Soupues published, in 1902, observations of three cases in which myosis, narrowing of palpebral fissure, and retraction of the eye-ball co-existed with tuberculosis of the apex of the lung. He attributed the phenomena to lesion of the dilator fibres of the sympathetic, which travel with the rami communicantes of the first dorsal nerve, and are consequently in close contact with the dome of the pleura. Widal treated a case in which hydatid cyst of the right lung co-existed with myosis of the same side in a man, aged 43. The myosis disappeared after operative treatment of the hydatid cyst. Other more recent writers on the subject have collected comprehensive statistics, which would go to show that such pupillary alterations are proportionately less frequent. Still, there is sufficient evidence to prove that they are often present, and the subject is one which must surely interest every attentive clinician.

HUNGARY.

Budapest, Sept. 13th, 1913.

THE TREATMENT OF ASTHMA.

ACCORDING to Dr. Prill the treatment of asthma must consist of hygienic, dietetic and medicinal medication. The hygiene includes life in the open air, with avoidance of climates of high altitudes, or where the winds are strong, where the barometric or thermometric variations are extreme. Humidity is bad for asthmatics. The wearing of woollen under-garments, moderate exercise, hydrotherapy, massage and alcoholic rubbings, followed by dry friction, are recommended. As regards diet, moderation, particularly at the evening meal (at which meats should be excluded) must be observed. He forbids game, pork, preserves, cheese, tomatoes, and asparagus especially. Tobacco and alcohol, he insists, are better avoided, and coffee should be drunk only in moderation. The medicinal treatment is indispensable. The use of iodide of potash is essential, and is to be given in daily doses of ½ to 1 gramme per day. Prill recommends the following formula:—

℞. Kalii iodati, 5.00.
Aq. dist., 150,00.
Antipyrini, 1.00.
Glycerini, 70.00.

N.D.S. Three tablespoonfuls daily, after meals.

Arsenical medication is also of value. The sodium arsenate, in the form of Fowler's solution, may be given to children over two years old in daily doses of 0.0002 for each year of age, and to the adult half a centigram. Dr. Terrai has recommended the following prescription:—

Acid. arsenicosi, centigrammes, .25.
Mucil. gumm. arab. } aa. q.s.
Aq. destill.
Ut fiant pilulæ No. 100.

D.S. Thrice daily one pill; to be taken after meals. To be used for months with intervals of 10–12 days.

Trousseau has recommended the following prescription:—

℞. Extr. belladonnæ } aa. centigramma
Pulv. radic. belladon. } unum, 0.01.
F. cum talibus dosibus pilulæ.

S. Give one daily and increase every other day with one pill.

The tincture of belladonna may be used, two drops for each year of age, in the child. Von Noorden uses the sulphate of atropine, 0.0001 grn. daily (one-tenth of a milligram), to be increased gradually until the daily dose is four-tenths of a milligram. The association of the various agents mentioned above may be used as follows: (*a*) for ten days in the month belladonna in its various forms may be administered; (*b*) for the rest of the month should be employed the following:—

Decocti rad. senegæ (3 : 100), 100.00.
Aq. dest., 100.00.
Tinct. lobeliæ, 5–10.00.
Arenicosi natrii, 0.004-0.10.
Kalii iodati, 1 to 5.00.
Kalii bromati, 1 to 10.00.
Cocaini hydrochlorici, 0.20.

M.D.S. One tablespoonful twice daily.

During this time, the patient should smoke, every other day, one of the Zematone, Niemayer or Wirth cigarettes, or one made as follows:—

℞. Folia bellad., 0.30.
Folio, hyoscyami,
Folia daturæ, aa. 0.75
Folia phellandii, 0.05.

Macerate in a mixture of
Gummy extr. opii, 0.015.
Cherry-laurel water, q.s.

Dry, cut fine, and make cigarettes with paper impregnated with the same liquid.

Electro-therapy has given excellent results. Every eight days the patient should get a pill containing 0.10 gm. aloes. During the attacks the windows should be opened, avoiding possible chilling; sinapisms should be applied to the feet; a little of the following ointment should be inserted into the nostrils:—

℞. Cocaine, 0.05.
Mentholi, 0.10.
Vaselin, 10.00.

The patient should inhale 5 to 15 drops of pyridine on a handkerchief, and smoke a Despic cigarette. He may inhale the vapour of water containing carbolic acid. Morphine (0.01) may be injected. If the heart is feeble, administer caffeine, or digalen. If asthma is a symptom of various morbid conditions, as bronchitis, emphysema, heart and renal disease, these should receive attention.

DR. SAMSON GEMMELL, of 17, Woodside Place, Glasgow, Professor of Medicine at the University of Glasgow, who died on April 2nd, aged 64, left, in addition to considerable real estate, personal estate valued at £106,546, of which £63,000 consisted of cash at the bank.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

GLASGOW.

Glasgow Sanatoria.

The Public Health Committee recommend the purchase of Bellefield Sanatorium by the Corporation, which sanatorium has, for nearly ten years, been conducted by the Glasgow and District Branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis. This step has been rendered necessary since the notification of tuberculosis, and the obligation to provide accommodation for patients suffering from such ailment being laid upon local authorities. Before the passing of the Act, persons suffering from tuberculosis were largely provided for by voluntary associations or by parish councils.

Bellefield Sanatorium is situated in Lanark, and is a substantial building, equipped on the most scientific lines. It has accommodation for fifty-two patients, and the grounds, which extend to about twenty-three acres, are unburdened. If the transfer is ratified it will make the second purchase by the Corporation for the treatment of tuberculosis; the Estate of Southfield having been purchased some time ago.

Sanitary Congress.

The thirty-ninth annual conference of the Incorporated Sanitary Association of Scotland was held in Glasgow on the 11th September and following days. At the annual general meeting held the evening previous (Wednesday, September 10th), Dr. Thomas W. Drinkwater, of Edinburgh, delivered a lecture in the Berkeley Hall on

Food and its Preparation,

illustrated by lantern views. Dr. Drinkwater, during the course of his lecture, remarked that our fault, or one of them, as a nation, was that our cookery methods were bad and wasteful, and that a French peasant woman could, with the aid of a little meat and a larger proportion of vegetables, make a tasty dish for her husband and family at a cost which would astonish the inhabitants of any of our towns, and this notwithstanding that her cooking apparatus had nothing in common with our kitchen ranges, and usually consisted of an earthenware pipkin, a handful of charcoal for fuel, and a stove. For this state of matters our cookery books were to some extent responsible, for they were the most unscientific instruction books that the lecturer knew. A little knowledge on the part of our housewives would alter this, and we should remember that to be scientific was to be methodical. He (the lecturer), did not think that many of our temperance reformers realised that bad cooking was the cause of a great deal of drunkenness. He did not wish to decry the higher education of women, and believed there were many women as capable of higher education as men, but there were many more who were qualified for a higher calling as that of motherhood and the management of a home, and he thought they would agree with him that a sound knowledge of cookery and household management was far more likely to render a home happy than a knowledge of classics. As perfect a food as could be obtained was a combination of milk and oatmeal, but this nutritious and wholesome dish was going out of fashion in Scotland. We often hear that the unhealthy condition of the poorer children in our towns was due to adulterated milk, or to milk from tuberculous cows, but on making an inquiry amongst the milk dealers in Edinburgh, especially amongst those serving the poorest localities, it was found that they sold more skim milk than sweet, because it was cheaper, and thus the children fed on such milk suffered from a want of fat, a condition which was very much intensified by the "jelly piece" in addition. Butter was too expensive, and they had a prejudice against margarine which was wholly unfounded. The health of these children would be immensely improved if margarine, or dripping, were given to them instead of jelly or jam. He thought that many people who maintain that they cannot take porridge were the subjects of fancy, for if porridge was well boiled it ought to be more digestible than bread. The general method of cooking meat exposed it at too great a temperature to ensure the best condition of the albumen. The ordinary method of cooking an egg was to boil it for three minutes (three and a half minutes if a fresh country one), with the result that the white part was hard and overcooked, the yolk being undercooked, as the yolk of the egg coagulated at a lower temperature than the white. If they boiled a pint of water and then put the egg in and drew the pan aside, allowing it to remain for twenty minutes, the egg would be found to be properly cooked, the white and the yolk equally, and neither hardened nor rendered indigestible. An advantage was to cover the pan with a modified tea-pot cosy.

He recommended the double vessel method of cooking, and remarked that steaming was a method much neglected, and said that frying had been described as the lazy housewife's companion, and believed it deserved the name. He would like to see the frying-pan take its place as an obsolete piece of cooking apparatus, to be tied up with ribbon and hung on the walls as an ornament, along with other strange things. If they wished to fry, a frying kettle should be used, and good frying oil, and the meat to be plunged bodily beneath the heated oil, as by the coagulation of the surface albumen it was sealed, and after cooking the extraneous fat was to be drained away.

Dr. William Robertson, Medical Officer of Health, Leith, in his presidential address at the Sanitary Congress dealing with

The Tuberculosis Problem,

said that tuberculosis must now be calmly recognised as a social sore demanding the application of many healing agencies at the hands of far-seeing and determined reformers, and their leading aim must be directed not so much to the cure of the ailment as to its prevention. Neither notification, elaborately equipped sanatoria, dispensaries, nor disinfection would attain the object they had in view, but rather the social elevation of the citizens of our country that would bring us within measurable distance of ultimate victory. It was true to say that the city dweller was less liable to attack from pulmonary tuberculosis than his neighbour of the country district, and although such a statement would cause dismay, yet facts and figures were at hand to prove it. In the urban districts of Scotland the reduction in the tuberculous death-rate had been greater for both sexes than in the rural districts, and the maximum death-rate amongst males in the country districts had been at an earlier age than amongst the town dwellers. Referring to the rural inhabitant and searching for a reason which caused this heavier incidence from tuberculosis, it was found that on a green hill-side fresh air was there in abundance, there was no fog to screen the health-giving rays of the sun, and on searching round it was realised that all the elements were at hand to defy such a disease as tuberculosis; but on stepping from the roadway and examining the house it was probably found that the roof was thatched and the ceiling low, the tiny windows, when the house was built, were never intended to open, and on the deeply recessed window ledge were packed together several pots in which grew some hardy plants, which effectually barred the entrance of sunshine, but which flourished at the expense of what light could reach them. On entering the house through the low doorway they were met with the odour of organically polluted air, and the floor gave under their feet as they approached the fireplace, where burned a fire, the embers of which had never been black for years.

It was in such a place as this—and there were hundreds upon hundreds of them in Scotland still in existence—that people were expected to lead healthy lives, and to rear boys and girls into healthy manhood and womanhood. It simply could not be done. Fresh air and sunshine were the watchword of the health official, and every house should be well lighted and ventilated. He was aware that many people would continue to live under deplorably bad hygienic conditions even when good, clean houses were provided for them, and the task of the health official must often begin and end with these irresponsible and lapsed persons. Dr. Robertson paid a high tribute to the work of the lady health visitor. The health official was greatly concerned by his knowledge that the section of the population which furnished the heaviest incidence from tuberculosis supplied itself with food badly chosen, badly cooked, and of inferior nutritive value. Poor wages were not always at fault here, as money was available for amusement, and even betting. Valuable body-building foodstuffs were either ignored or unknown, and the mere mention of rice, beans or lentils to the poorer classes was treated with insignificant scorn and disgust; porridge was seldom used, because the housewife was too lazy to make it. Milk was too expensive and milk puddings unpopular. Yet it was upon "put off" meals, to give them their deserved name, that our principal wage-earners were expected to thrive and remain in good health.

No wonder we had so much tuberculosis, especially when bad environment was accompanied by lack of nourishment, and it was a deplorable fact that many of the workers amongst the labouring class spent at least one-sixth of his weekly wages upon alcoholic beverages, and he was sorry to say that it was the inhabitant of the one-and-two-roomed house who provided some very sorry examples of excessive alcoholic indulgence, and although he did not aspire to solve the drink problem he was certain that when the suggestions for securing better houses, better feeding methods, and less abuse of alcohol were placed before them in a workable form, they would be depended upon to demand a considerable amount of success.

Dr. W. F. Brown, Medical Officer of Health, Ayr, said, in discussing the "Powers of Inspection as Foreshadowed in the Prospective Milk Legislation, 1913," that it was absolutely necessary for the appointment of a bacteriologist if they were to make any progress in milk inspection. He thought the American methods were almost ideal, and that our recent legislation was just copying these methods.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

FRENCH SANITATION AND ENGLISH CRITICS.

To the Editor of The Medical Press and Circular.

Sir,—It is well that someone should undertake the thankless task of pointing out the defectiveness of French drainage and house sanitation generally. Any English traveller who has gone off the track usually affected by his countrymen will realise the truth of the picture so graphically presented in your columns a week or two ago. As a medical man with a fair experience of public health work, I have a fairly cultivated olfactory sense for the detection of sewer gas. I may say that the odour is rarely absent from hotels in France or from the dwelling houses I have visited. It is, of course, unsafe to draw conclusions from a limited number of observations taken under particular conditions. Nevertheless one may to some extent infer that the defective standards of the hotels are more or less prevalent in the homes of private citizens. Englishmen are in some ways a curiously tolerant race, otherwise the deplorably bad sanitary state of the average French hotel would have put a stop to the constant flow of tourists and visitors across the Channel.

But can we as a nation afford to throw stones at France? I admit that our hotels and our private dwelling houses as a general rule are well equipped and well maintained from a sanitary point of view. But what of our railways? I could give plenty of instances in which the closets in railway stations are grossly and scandalously defective. Why should not the Medical Officer of Health assert his powers over our railway stations? Is there any legal obstacle in his way? Then, again, the closets in the corridor trains are often filthy and ill-supplied with water. Whose duty is it to inspect and enforce a proper care of water closets in a railway train? Then, again, some excursion trains are run for long journeys without corridors and without sanitary conveniences for passengers. Such a state of things should be impossible in this present year of grace. Nor is the evil lessened by the fact that the train often does not stop at intermediate stations at all, or, should it do so, it remains too short a time for the passengers to obtain the necessary relief in the station lavatory.

These matters are of much importance to the travelling public. I trust, Sir, you will thresh the matter out in your valuable journal, among the readers of which must be many able to furnish valuable observations as to facts and suggestions as to remedying sanitation.

I am, Sir, yours truly,
September 11th, 1913. Anglo-Indian.

MEDICAL MEN UNDER THE INSURANCE ACT.

To the Editor of The Medical Press and Circular.

Sir,—Your editorial comments in the "Educational number" about the betterment of the medical profession through the Insurance Act suggests this query, and I trust you will not think it a liberty if I ask you to publish it.

Which is the worse, and what is the difference between seeing patients at an open surgery at a cheap rate, and seeing the same or better class under the Insurance Act for the same remuneration, or less?

The answer, I take it, would be that under the Act the doctor is a contract slave, and in the other case a free man and therefore better off. Oh, for a good trades union! As I am on the panel, I depart from my usual practice of signing my name and subscribe myself,

Yours truly,
London, S.W. An Old Radical.
September 13th, 1913.

P.S.—My panel returns less than surgery rates.

OBITUARY.

DR. FRANK BUSZARD, OF NORTHAMPTON.

The death is announced of Dr. Frank Buszard, of Dallington, near Northampton, at the age of 74. The deceased was the younger son of Dr. Marston Buszard, M.D., of Lutterworth, the younger brother of Mr. Marston Buszard, K.C., Recorder of Leicester. He qualified as M.R.C.S.Eng. in 1860, becoming F.R.C.S. in 1864, M.D Lond. in 1865. He was elected F.R.C.P.Lond. in 1887. For over 60 years he was connected with Northampton Hospital, being the Senior Honorary Physician for nearly half a century. In recognition of his services he was presented in March, 1912, with his portrait in oils. In making the presentation, the late Lord Northampton described him as "an ornament to a noble profession," and added, "He has devoted over half a century as Honorary Physician without any thought of return." In reply Dr. Buszard said that when he first went to Northampton he was the only house surgeon at the hospital, although there were over 150 beds and nearly 6,000 out-patients. Hospitals were then emerging from the "Sairey Gamp" stage. The night nurses were simply charwomen, who worked hard during the day and added to their income by sitting up at night, generally asleep in armchairs. Dr. Buszard was one of the pioneers of hospital reform, which he advocated at medical congresses throughout the country. He was instrumental in effecting great improvements at Northampton, which came to be regarded as a model institution. He was the leader of the Unionist Party at Northampton for many years. He was also a magistrate for the borough of Northampton. He leaves a widow, two daughters and one son to mourn his loss.

DR. C. K. MORRIS, OF BLACKHEATH.

We regret to record the death of Dr. Clarke Kelly Morris, J.P., which took place suddenly from heart failure at his residence, Gordon Lodge, Blackheath, on the 31st ult., aged 58. The deceased was the son of Dr. Edwin Morris, who was in practice in Spalding, Lincolnshire. He came to Blackheath in July, 1880, entering into partnership with Dr. Peter Cooper, of Stainton Lodge, Shooter's Hill Road, Blackheath, they subsequently being associated with Dr. Finch White and Dr. Lionel Hooper, of Westcombe Hill. Dr. Clarke Morris, who studied at St. Thomas's Hospital, was admitted M.R.C.S.Eng. and L.S.A.Lond. in 1877. He was Hon. Consulting Surgeon to the Blackheath and Charlton Hospital, Hon. Local Secretary and Treasurer of Epsom College, and Fellow of the Obstetric Society. Formerly he was Surgeon to the Johnston Hospital at Spalding and to the Royal Kent Dispensary (now amalgamated with the Miller General Hospital in Greenwich Road), Medical Officer of Health for the Spalding Urban District Council, and Resident Clinical Assistant at the City of London Hospital for Diseases of the Chest. Dr. Morris was appointed on the Commission of the Peace for the County of London about twelve years ago, and by his colleagues of the Blackheath Bench he was highly esteemed; his level-headed reasoning was an asset of great value in their deliberations.

MEDICAL NEWS IN BRIEF.

The Cost of London Hospitals.

The statistical report on the ordinary expenditure of 109 London hospitals for 1912 has been submitted by the Honorary Secretaries of King Edward's Hospital Fund to the Duke of Teck, Lord Iveagh, and the Speaker, governors of the fund. There were 9,233 beds in average daily occupation in the London hospitals during 1912. The total number of in-patients admitted during that year was 134,647, while 1,529,197 patients attended at the out-patient departments. The total ordinary expenditure during the year at these hospitals, including maintenance, administration, rent, rates, and taxes, but excluding expenditure on improvements and additions or other capital expenditure, and also before charging interest on borrowed money, amounted to £1,038,791. The total income of these hospitals from all sources, including the legacies received during the year, would not, by a large amount, have sufficed to meet the annual working expenditure (apart from the cost of improvements and additions or other capital expenditure) but for the grants made by this fund and the Metropolitan Hospital Sunday and Hospital Saturday Funds. They regret to see that the increase in the cost per bed occupied and per attendance of out-patients, first noted in 1911, has continued, the addition in 1912 representing about £21,800.

Daring Robbery at the House of a London Medical Man.

Harry Mansfield, aged 21, of Wyndham Street, Marylebone Road, was sentenced last week by Mr. Paul Taylor, at Marylebone, to six weeks' hard labour for stealing £4 cash, a gold watch, gold albert, gold matchbox, gold cigar piercer, and a sovereign purse, together representing between £65 and £70, the property of Mr. James Sherren, Devonshire Place, W. A detective said that he called at a pawnbroker's in East Street, Marylebone, on business, and there saw Mansfield trying to pawn some jewellery. The articles were returned to the accused by the pawnbrokr, and when Mansfield left the shop the detective followed him and asked him where he obtained the property. Mansfield said that it belonged to him, but the detective told him that the articles corresponded with property reported to have been stolen from Mr. Sherren's house, and he should arrest him. At the police-station Mansfield said that he was passing Mr. Sherren's house, and seeing the area gate and door open he seized the opportunity and entered the house. There was nobody in the kitchen, so he went upstairs and went into nearly every room in the house and helped himself to what he could find. When he heard someone coming he secreted himself in a cupboard. On leaving his hiding place he dropped a new screwdriver and left it behind him, regarding that as a good exchange for the booty he had secured. He then left the house by the front door. Mr. Sherren said that the property was taken from his dressing room. The children and servants were away, and he was at dinner in the dining room.

The Marienbad Cholera Case.

It is reported that the persons in the Isolation Hospital at Marienbad who had come into contact with the lady who recently arrived there from Bosnia suffering from cholera were at the expiration of their period of isolation on Monday last pronounced to be perfectly well, and it is announced that there is now no danger of the disease being spread through their medium. Frau Garcinstsa, the cholera patient in question, is making good progress towards recovery.

Plague in East Africa.

It is announced from Zanzibar that an epidemic of plague and cerebro-spinal meningitis which has recently broken out in East Africa now extends from the coast to Victoria Nyanza, Mombasa, Nairobi, and Kisumu are affected. The total number of cases is 452; the deaths are 328.

The Royal Institute of Public Health.

A course of instruction for candidates as Tuberculosis Officers, General Practitioners and others, will be opened on Oct. 10th with an introductory address by Prof. G. Sims Woodhead, M.D., LL.D., F.R.S.Edin., followed by a series of eleven weekly lectures by well-known authorities—viz., Dr. Charles Porter, Dr. A. Conyers Inman, Dr. J. Edward Squire, Dr. T. N. Kelynack, Mr. Henry J. Gauvain, Dr. Cecil Wall, Dr. Clive Riviere, Dr. Halliday Sutherland, Dr. Thomas D. Lister, Dr. Alfred Greenwood and Dr. H. Owen West. Bacteriological demonstrations will be given in the laboratories of the Institute (Russell Square, London), and visits arranged to Sanatoria, tuberculosis dispensaries, etc. Fee for the course, three guineas. The lectures will be delivered in the Lecture Room of the Institute on Fridays at 5 p.m. All interested are invited to attend at introductory lecture.

Sanatoria at Farnham.

At a meeting of the managers of the Farnham (Surrey) Isolation Hospital last week it was reported that the Urban Council for the neighbouring district of Aldershot had offered the Hampshire County Council six acres of land owned by them at Hale, which is in the rural district of Farnham, for the purposes of a sanatorium, and that the offer was being considered by the Hampshire Insurance Committee, and also by the Public Health Committee of the county. There are already a number of such institutions in the Farnham district, and the opinion was expressed that the introduction of another would be disastrous to the welfare of the locality.

NOTICES TO CORRESPONDENTS, &c.

☛ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial,* and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Reprints.—Reprints of articles appearing in this Journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

A Correction.—The annual dinner of past and present students of St. Mary's Hospital Medical School will be held at Princes' Restaurant at 7 p.m. on Thursday, October 2nd, not on October 7th, as previously announced. Mr. Horace Sworder will preside, and the Hon. Secretary is Mr. Y. Warren Low, 146 Harley Street, W.

A. R. M. (Cornwall).—It is a well-known fact that insanity is closely allied to genius. The following celebrities have been declared to be either epileptic, insane, or born of a neuropathic stock:—Alexander the Great, Julius Cæsar, Napoleon, Peter the Great, Frederick the Great, Pitt, Earl of Chatham, Mahomet, the Apostle Paul, Martin Luther, Emmanuel Swedenborg, and others. Among English poets, Cowper, Wordsworth, Byron, Gray, Burns, Chatterton, Thompson were either insane or possessed the neuropathic temperament.

Mr. V. Palmer (Russell Square, W.C.).—Our correspondent would do well to consult *The Ship Surgeon's Handbook*, by A. V. Elder, M.R.C.S., L.R.C.P., second edition. (London: Bailliere, Tindall, and Cox, 1911, price 5s.)

Dr. S. T. (London, N.).—One of the best night commodes we have come across is the Portable Sanitary Water Closet, patented by Mr. Tom Jones, of Parkdale, Sedgley, near Dudley, which is self-contained, thoroughly sanitary, not unsightly, and reasonable in price.

F.R.C.S.Edin. (N. Wales).—Quinine amblyopia differs from that due to tobacco in that in the former the rods are poisoned, whereas in the latter the function of the cones is destroyed. As a rule the prognosis is worse in the former than in the latter.

Appointments.

Davies, Trevor Berwyn, M.D., B.S.Lond., B.Sc., M.R.C.P.Lond., Registrar and Pathologist to the Hospital for Women, Soho Square, London.

Dickson, William Arnott, M.D., Ch.B.St.And., F.R.C.S.Edin., D.P.H., Tuberculosis Officer for Gloucestershire.

Dykes, Andrew Leslie, M.D.Edin., D.P.H.Lond., Assistant Medical Officer of Health of the County Borough of Oldham.

Henderson, John, M.D., Ch.B.Glasg., F.R.F.P.S.Glasg., Visiting Physician to the Glasgow Royal Infirmary.

Vacancies.

Carlisle Non-Provident Dispensary.—Resident Medical Officer. Salary £200 per annum, with apartments. Applications to the Hon. Secretary, Mr. G. A. Lightfoot, 23 Castle Street, Carlisle.

Royal Sea Bathing Hospital for Surgical Tuberculosis, Margate.—Resident Surgeon. Salary £120 per annum, with board, residence, and laundry. Applications to the Secretary, R.S.B.H. Offices, 13 Charing Cross, London, S.W.

Swansea General and Eye Hospital.—House Surgeon. Salary £100 per annum, with board, washing, and attendance. Applications to W. D. Hughes, Secretary.

St. Mary's Hospital for Women and Children, Plaistow, London, E.—Senior Resident Medical Officer. Salary £100 per annum, with residence, board, and laundry. Applications to the Secretary.

Canterbury Mental Hospital, Canterbury.—Assistant Medical Officer. Salary £200 per annum, with board, lodging, washing, and attendance. Applications to the Medical Superintendent.

Wrexham Infirmary.—Resident House Surgeon. Salary £120 per annum, with board, lodging, and washing. Applications to the Secretary, 7 Hill Street, Wrexham.

Birmingham City Asylum, Rubery Hill, Birmingham.—Junior Assistant Medical Officer. Salary £200 per annum, with furnished apartments, board, laundry, etc. Applications to the Medical Superintendent.

Stockport Infirmary.—Junior House Surgeon. Salary £100 per annum, with board, washing, and residence. Applications to the Secretary.

Rochdale Infirmary.—Second House Surgeon. Salary £100 per annum, with board, residence, and laundry. . Applications to T. Elvyn Kershaw, Secretary.

Somerset and Bath Asylum, Cotford, Taunton.—Assistant Medical Officer. Salary £180 per annum, with furnished apartments, board, fuel, lighting, washing, and attendance. Applications to the Medical Superintendent.

The Royal Infirmary, Hull.—House Physician. Salary £100 per annum, with board and furnished apartments. Applications to the Chairman of the House Committee.

The Royal Infirmary, Hull.—Assistant House Surgeon. Salary £100 per annum, with board and lodging. Applications to the Chairman, House Committee.

Births.

Clarke.—On September 13th, at Bank House, Morley, to Dr. and Mrs. Fraser Clarke—a daughter.

Gallie.—On September 11th, at the Guards' Depot, Caterham, Surrey, the wife of Major Stuart Gallie, R.A.M.C., of a daughter.

Hardie.—On September 14th, at 15 Wood Street, Barnet, the wife of Charles F. Hardie, M.A., M.B., of a son.

May.—On September 9th, at Sowton, Gerrard's Cross, the wife of Walter J. May (*née* Madge Litteljohn), of 24 Upper Wimpole Street, W., of a son.

Ogle-Skan.—On September 7th, at 157 Audley Road, Hendon, N.W., the wife of H. W. Ogle-Skan, M.R.C.S., L.R.C.P., of a son.

Penrose.—On September 10th, at 32 West Bar, Banbury, to Dr. and Mrs. N. C. Penrose—a daughter.

Walton.—On September 11th, at 1 Weymouth Street, Portland Place, W., the wife of Albert J. Walton, M.S., F.R.C.S., of a son.

Marriages.

Adeney—Adeney.—On September 9th, George Cuthbert Adeney, M.R.C.S., of Tunbridge Wells, son of Rev. Walter F. Adeney, D.D., late of Manchester, to Hilda Caroline, daughter of E. S. Adeney, of Edgmond, Gerrard's Cross.

Barker—Morrison.—On September 4th, at St. Margaret's Church, Northam, Robert Sidney Barker, M.B., B.S., of Greenwich, son of the late Robert Barker, of Whitehaven, to Frances Muriel, daughter of the late William Henry Brown Morrison, of Wakefield, and Mrs. Morrison, of Allerton, Weybridge.

Deaths.

Bate.—On September 11th, at 2 King Edward Road, South Hackney, N.E., Elizabeth, wife of George P. Bate, M.D., in her 73rd year.

Buszard.—On September 14th, at Dallington, Northampton, Frank Buszard, J.P., M.D.Lond., F.R.C.S.Lond., F.R.C.S.Eng., for many years Senior Physician to the Northampton Hospital, younger son of the late Marston Buszard, M.D.Edin., of Lutterworth, aged 74.

Lathbury.—On September 11th, at 4 Burlington Place, Eastbourne, Florence Jane, the beloved wife of Arthur Edward Lathbury, M.R.C.S., L.R.C.P., of Eastbourne.

Nix.—On September 11th, after a short illness, Edward James Nix, M.D., of 11 Weymouth Street, W., aged 69.

Pauli.—On September 2nd, at "Sandringham," Locking Road, Weston-super-Mare, George William Pauli, L.R.C.P. and S.Edin., L.F.P.S.Glasg., aged 45.

Richardson.—On September 3rd, at 71 Upper Richmond Road, S.W., John Howard Humphrey Richardson, M.R.C.S.Eng., L.S.A.Lond.

Tennent.—On September 13th, at 159, Bath Street, Glasgow, Gavin Paterson Tennent, M.D.

OPERATIONS—METROPOLITAN HOSPITALS.

WEDNESDAY.—St. Bartholomew's (1.30 p.m.), University College (2 p.m.), Royal Free (2 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. Thomas's (2 p.m.), London (2 p.m.), King's College (2 p.m.), St. George's (Ophthalmic, 1 p.m.), St. Mary's (2 p.m.), National Orthopædic (10 a.m.), St. Peter's (2 p.m.), Samaritan (9 30 a.m. and 2.30 p.m.), Gt Ormond Street, (9.30 a.m.), Gt. Northern Central (2.30 p.m.), Westminster (2 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), Cancer (2 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).

THURSDAY.—St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), University College (2 p.m.), Charing Cross (3 p.m.), St. George's (1 p.m.), London (2 p.m.), King's College (2 p.m.), Middlesex (1.30 p.m.), St. Mary's (2.30 p.m.), Soho Square (2 p.m.), North-West London (2 p.m.), Chelsea (2 p.m.), Great Northern Central (Gynæcological, 2.30 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), St. Mark's (2 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).

FRIDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), Guy's (1.30 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. George's (1 p.m.), King's College (2 p.m.), St. Mary's (2 p.m.), Ophthalmic (10 a.m.), Cancer (2 p.m.), Chelsea (2 p.m.), Great Northern Central (2.30 p.m.), West London (2.30 p.m.), London Throat (9.30 a.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), City Orthopædic (2.30 p.m.), Soho Square (2 p.m.).

SATURDAY.—Royal Free (9 a.m.), London (2 p.m.), Middlesex (1.30 p.m.), St. Thomas's (2 p.m.), University College (9.15 a.m.), Charing Cross (2 p.m.), St. George's (1 p.m.), St. Mary's (1 p.m.) Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).

TUESDAY.—London (2 p.m.), St. Bartholomew's (1 30 p.m.), St. Thomas's (3.30 p.m.), Guy's (1.30 p.m.), Middlesex (1.30 p.m.), Westminster (2 p.m.), West London (2.30 p.m.), University College (2 p.m.), St. George's (1 p.m.), St. Mary's (1 p.m.), St. Mark's (2.30 p.m.), Cancer (2 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), Royal Ear (3 p.m.), Samaritan (9.30 a.m. and 2.30 p.m., Throat, Golden Square (93.0 a.m.), Soho Square (2 p.m.).

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVII. WEDNESDAY, SEPTEMBER 24, 1913. No. 13.

NOTES AND COMMENTS.

A "Black" Doctor.

A CURIOUS sidelight was thrown upon our national prejudices against coloured folk by a recent incident at Camberwell. It appears that the local guardians had advertised a vacancy for a district medical officership and there were two applicants for the post. On the day of appointment the name of one only, an Englishman, was brought before the meeting. A member pointed out that under the circumstances it was not possible to make a selection, and it was then gently intimated to him that it had not been thought advisable to bring the second applicant before the Board on the ground that he was a "black" man. Thereupon followed a discussion on lines not altogether unfamiliar. One of the members protested warmly against the exclusion of a candidate on account of the colour of his skin. That attitude he condemned as contrary to what we are taught about proper feeling towards our brothers. He was opposed by a medical man, who remarked that the duty of the medical officer was to attend the poor, who were fastidious enough to refuse attendance by a man of colour. The upshot of the matter was that the exclusion was supported by fifteen votes to eight.

Other Cases.

IN support of his argument the medical member cited the case of a coloured midwife from the West Indies who settled in the district, but whom none would employ. His further evidence, however, cut both ways, for he stated that the coloured applicant, if appointed, would not give up an appointment in Marylebone. The nature of the latter post was not mentioned, but it is evident that the prejudices of Camberwell are not altogether endorsed in Marylebone. This question of colour, in point of fact, is constantly cropping up in various parts of the Kingdom. The present writer recalls the throwing out of an application some years since for a junior house surgeoncy in a London hospital, and the appointment of an unsuitable man. The plain fact of the matter is that any man of colour who elects to practice medicine in the United Kingdom must be prepared to face an enormous amount of opposition. It has been shown again and again that it is possible to gain a living under such circumstances, and in some cases to attain considerable and even brilliant success. Any man of colour, however conscious though he be of great natural gifts and of an iron resolution, will find his passage through life infinitely smoother if he cast his professional lot amongst his own countrymen.

Cholera in Europe.

HAPPILY, the news that cholera is abroad in Europe no longer alarms the sanitary authorities in the United Kingdom. Here at home the lessons of practical science have been rigidly applied, and the careful guarding of the water supplies has rendered the country almost safe from invasion by cholera. Fifty years ago there would have been a considerable risk of a spread of any serious Continental outbreak to our country. At the present moment cases of the disease are reported from various parts of Europe. The epidemic has originated in the Far East under the favouring conditions of the Balkan War. It has doubtless been distributed far and wide by disbanded soldiers. Cases have occurred in St. Petersburg, and numerous districts of Russia have been also invaded. One case has occurred at Prague and another at the famous Bohemian watering place—Marienbad. It would be difficult to imagine a greater mishap to that popular spa. A Reuter's telegram from Bucharest states that the Roumanian Ministry of War anticipates a speedy end to the epidemic, which has so far destroyed 1,500 men out of a force of 500,000.

London is not Safe from Cholera.

As a water-borne disease, needless to say, cholera is preventable. In the United Kingdom close attention has been paid to the purity of our drinking water supplies, with the result that the disease has been kept at bay for more than a generation. For all that, our sense of security is, to a certain extent, based on a foundation of sand, owing to the fact that many of our large centres of population are supplied with water taken from sewage infected rivers. The case of London is notorious. There is a large aggregate amount of sewage discharged into the Thames above the intakes of the water companies. The saving clause is that as a rule a cholera patient would not be likely to infect the upper reaches of the river with his evacuations. Let such a contingency happen, however, and the metropolis would be brought face to face with the possibility of a vast outbreak of cholera. A precisely similar thing might well occur in the case of the Severn and the Trent, rivers which supply many towns and villages in their course. The fact that comparatively pure water is obtained for London and certain other great towns is no excuse for using sewage contaminated water as a drinking supply. Liverpool, Manchester, Birmingham, and other great towns have obtained supplies that are above suspicion. Why not London, the greatest and richest city in the world?

Dr. Jelley in the Public Eye. DR. JELLEY, the better known as the "Threepenny Doctor," has had a good many unfortunate collisions with the powers that be, legal or otherwise, in the East End of London. Last week he prosecuted a man who appears to have attempted to paste bills upon his windows in the presence of a disorderly mob. On that occasion the man was fined. A fortnight ago Dr. Jelley appeared before Coroner Westcott at Shoreditch. It appears that he had refused a certificate of death to the parents of a child who had died of summer diarrhœa, and whom he had seen twice only on the day before death. Asked why he had not given a certificate, he said that he refused because on four or five previous occasions registrars had refused to accept his certificates in cases in which he had not seen deceased persons one day before death. He regarded such action as impertinent. The coroner agreed that the registrars had no right to make laws of their own. That opinion we emphatically endorse. Any medical man whose certificates have been wrongly refused by a registrar would do well to go on granting certificates, as the onus of refusal and of the subsequent inquest would in that way be thrown upon the registrar.

Clerks and Death-Traps. MUCH has yet to be discovered, even in a civilised country like our own, about "man's inhumanity to man." Somewhere in the background of the countless thousands of toilers who have occasion to mourn their lot is quite an army of under-paid city clerks, to whose grievances public attention has recently been called. The sight of a procession of masked men and women, members of the National Union of Clerks, marching to Hyde Park the other day, where a meeting was held to protest "against working in death-traps," is sufficient comment upon the bad conditions under which many thousands of clerks have to work. The low wages, long hours, unpaid overtime, and unhealthy surroundings, with which they have to contend is only dimly realised by the general public, who never have the opportunity to peep behind the scenes after closing time, or to descend to dark and ill-ventilated basements where much of the clerical work is carried on. Nor are the city firms the only offenders in this respect. In one of the best-known West End drapery establishments, whose name is almost a household word, we have it on good authority that there exist underground offices in which human beings are made to toil whose only means of communication with the outside air is by a few tiny holes in the pavement, through which the street dust, swept by porters, descends in germ-laden showers upon the heads of the unfortunate clerks cooped up beneath. Nothing of this is visible, of course, to the public, and, worse still, no medical officer of health or sanitary inspector, let alone a Factory Act inspector, appears to have condemned the premises. Small wonder is it if the workers in such places become anæmic, suffer from chronic headache, or develop phthisis. The only remedy for such a state of affairs, which is a blot upon our civilisation, is an extension of the powers of medical inspection to all offices, rooms and places where clerical work is done, whether underground or otherwise. Underground bakehouses are rigorously inspected, why not, then, subterranean offices?

LEADING ARTICLES.

THE FRIENDLY SOCIETIES AND A STATE MEDICAL SERVICE.

THE idea of a State medical service has been often discussed of late years and has secured many adherents, both inside and outside the medical profession. Briefly defined, it may be described as a special department of the State organised for the purpose of providing medical service to all or any citizens as required, the cost to be paid for out of the national exchequer. It does not follow that medical aid would be asked for or accepted by all classes of citizens, any more than they avail themselves of the State church or of State education, or of the old age pension: public services to each of which in theory every subject is entitled to take advantage. So, too, with the hospital accommodation for fever cases provided in many districts out of the public purse. Any ratepayer may avail himself of that accommodation free of expense, but, as a matter of fact, its use is practically confined to the poorer classes of society. It is well to make this point clear, as the comprehension of the meaning of a State medical service has been to some extent obscured by the assumption that such an organisation would cater for the middle and upper classes, and in that way would lead to the dislocation of private medical practice. Such a sequence has not followed in the case of free State education, which certainly has not materially damaged the interests nor lessened the attendance at the better class private and the public schools. The principle of a State service has, of course, been formally adopted long ago in the Poor law legislation of the British Parliament. It has recently been greatly extended in the National Insurance Act, which, indeed, has brought the matter into general notice, if not actually within the range of practical politics. It is of considerable interest to have an opinion as to its merits or otherwise from those most directly concerned in a change of the kind in question. A declaration of the kind has come opportunely from the National Conference of Friendly Societies, which met last week in London. The gathering represented a membership of over 7,000,000 and a total revenue for 1912 of £7,492,051. Its views, therefore, carry weight and authority. It is interesting to learn that the Conference rejected resolutions in favour of a State medical service, while, on the other hand, they adopted a resolution urging the transference of medical benefits to approved societies. To read between the lines of this declaration is not an easy matter. The State has seen right to take over the administration of medical benefit from the societies, who were providing at four to six shillings per annum for a portion only of the far larger number of insured persons who were now paid for by the State at the rate of nine shillings per annum. The friendly societies are now faced with the difficulty of malingering and over-insurance. So long as human nature exists on its present lines so long will there be the temptation for an insured person who can draw more sick pay from the State and his society than the total amount of his wages to do so by an exaggeration or an actual counterfeiting of illness. The societies, however, have had over-insured members in their own ranks for many years, and the remedy then, as now, was in their own hands. As to the demand that the administration of medical benefit should be handed over to the friendly societies it is extremely unlikely that such a step will ever be taken; their relationships with the medical profession in the past discourage any such probability. It would be well if the medical profession were to take a hint from the National Conference of the Friendly Societies so far as the timely and careful discussion of the pros and cons of a State service are concerned. It seems hardly conceivable that the medical world has not considered the matter carefully and made up its mind as to the policy most likely to conduce to its future welfare. The problem of the State service has been greatly advanced and a clear understanding of its merits and demerits could not fail to strengthen the hands of the medical profession when called upon to treat it in the form of practical social legislation.

CURRENT TOPICS.

Experiments on Living Animals.

In a return showing the number and nature of experiments on living animals during 1912 under licences granted by Act of Parliament, recently published by the Home Office, it is stated that the total number of such experiments was 83,599, being 11,604 less than in 1911. Of these 78,556 experiments were performed by inoculation, hypodermic injection, and other means, without anæsthetics. The latter were mostly injections, but a few were feeding experiments, or the administration of various substances by the mouth or by inhalation, or the abstraction of blood by puncture or simple venesection. In no instance has a certificate dispensing with the use of anæsthetics been allowed for an experiment involving a serious operation. In a very large number of the experiments without anæsthetics the results are negative and the animals suffer no inconvenience whatever from the inoculation. These experiments are therefore entirely painless, a fact which may well be taken into consideration by the opponents of experimental research. Among the places registered for the performance of experiments is a sewage farm, where the character of an effluent may be tested by its effects upon the health of fish. The new places include Aberdeen (University), Ayr, and Cambridge (Research Hospital), Greenwich (Royal Naval College), Dumfries, Glasgow (University), Oxford (University), and Whitchurch (Glamorganshire). In London two fresh places were registered—the London School of Medicine for Women and the Royal College of Physicians and Surgeons (laboratories in Queen Square, Bloomsbury). The registration of the conjoint laboratory of the two colleges situated on the Victoria Embankment was cancelled. There are now 45 cities and towns where vivisection is authorised, London having 27 registered laboratories, Glasgow 14, Edinburgh 11, Aberdeen, Ayr, Cambridge, Cardiff, Manchester, Newcastle and Wakefield two each, other towns possessing one only. To licensees who returned experiments during 1912 590 certificates were granted dispensing with anæsthetics, 364 dispensing with the obligation to kill the animal before it recovered from anæsthesia, and 64 permitting experiments in illustration of lectures. There were no certificates for the further advancement of knowledge by testing previous discoveries, another fact of importance for platform speakers upon the subject. Much valuable work in connection with therapeutics and practical medicine has been carefully and conscientiously carried out by the various licensees in registered laboratories up and down the country.

The Dying Leech.

At a recent inquest in London surprise was expressed that leeches were still employed in medicine, the Coroner remarking that he thought they had gone out of use a half-century ago. As a matter of fact, over 60,000 leeches are sold in Great Britain every year, many thousands having to be imported from the Continent. There was a time, of course, when professional "leech-bleeders" plied their trade with much success, while the application of leeches was regarded as quite an orthodox practice by medical men, who were wont to bleed their patients every spring and fall. The systematic use of the leech was well known to the ancients, and its special property was referred to by Horace—*non missura cutem, nisi plena cruoris hirudo.* The rapid depletion of blood produced by such means is of distinct value in cases of engorgement of the right side of the heart or congestion of the liver, while in certain classes of practice the leech still finds favour in cases of black eyes and other painful contusions. Special breeding ponds are employed for leeches, the finest specimens coming from Hungary. If the faithful leech has now wriggled into comparative obscurity it is because the modern practitioner prefers a more scientific method for relieving pain and congestion, though it must be admitted that venous disgorgement can be carried out quite effectively by this harmless little creature when intelligently applied.

Influenza upon Virgin Soil.

It is always interesting to trace the course of an infection newly introduced among a community and to watch its effects upon fresh types of humanity. Such an outbreak is recorded in the *Guy's Hospital Gazette* by Staff-Surgeon R. W. B. Hall, R.N., the disease being influenza and the community the inhabitants of the small island of St. Kilda, the most westerly of the group of islands known as the Outer Hebrides. St. Kilda is only about two miles in length by one and a quarter at its greatest breadth, and boasts a population of seventy-nine. On June 20th last, H.M.S. *Active* was directed to proceed as soon as possible to the relief of the islanders who were reported to be suffering from a severe epidemic of influenza. The infection is believed to have been imported by a pleasure steamer from Glasgow, and on June 12th the entire population, with the exception of six, were suddenly attacked with a respiratory type of influenza, with severe headache, great pain in the eyes, burning skin, dryness of mouth and throat, persistent, dry cough, intense pains and aching in the limbs, and great prostration. The temperatures ranged from 99° to 104°. Only three or four cases showed physical signs of bronchitis. Most of the patients, inmates of stone cottages, were found huddled up in shawls with the one window tightly closed and the room full of fumes from a peat fire.

The relief party soon set to work and converted the church into a temporary hospital, the adjoining schoolroom being used as a dispensary, store, kitchen, etc. Meanwhile an expedition was organised by the authorities in Edinburgh, consisting of a Medical Officer of the Local Government Board, an Inspecting Officer, and two nurses, with stores and provisions. By the morning of the 24th the patients had considerably improved, so that the hospital was dismantled and restored to its proper condition of parish church. The six patients who had escaped infection were too feeble to render assistance, so that the islanders were, indeed, in a bad way, all being struck down together. When the news of the outbreak was received it was at first feared that the disease might have been typhus. The only other grave epidemic from which St. Kilda has suffered is that of small-pox, in 1724. Fortunately, in the present outbreak the infection was not of a very virulent type.

The Use of Dried Milk.

Of the numerous devices adopted by modern science to render the natural milk of animals, especially of the cow, free from objectionable qualities, none are so uniformly successful, perhaps, as that of drying. In the original Just-Hatmaker process for the manufacture of dried milk upon the large scale, the milk was allowed to fall upon revolving steel cylinders at a white heat, the resulting milk scales being reduced to powder by metal teeth. When this powder, which is light and flocculent, is mixed with water the original colour and flavour of the milk is reproduced. As a matter of fact, the milk retains its natural antiscorbutic properties, so that infants fed on a good brand of dried milk do not develop any of the deficiency diseases. This point was brought out by Dr. A. E. Naish, Senior Assistant Physician to the Royal Hospital, Sheffield, in a paper read before the recent Conference on Infant Mortality held at the Caxton Hall, (a) who followed up as many infants as possible up to the ages of three, four and five years. Regarded as a substitute for fresh cow's milk, dried milk answers remarkably well in infants' milk depôts, where this commodity can be retailed in measured quantities with far less risk of contamination than there is with ordinary milk. From the point of view of storage and distribution, powdered milk possesses great advantages over the fluid product, since it can be sent by post or packed in tins. Travellers upon the Continent find dried milk very useful for purposes of tea-making, when they cannot get anything else. Moreover, the germ-content of dried milk is exceedingly low, so that it deserves to occupy a high place in the treatment of infantile and other forms of epidemic enteritis prevalent at this season of the year.

The New Agnosticism.

The wisdom of the old agnostics consisted in knowing how little they knew. That seems a conclusive proposition, but we have improved on it. Sir Oliver Lodge at the British Association stood out as the rather exaggerated apostle of the new agnosticism. We may not follow him everywhere, but his mind is typical of the fashion of the day, and as such is to be studied. In the old days theology said it knew. It laid down a law on foundations of faith, and upheld it throughout. Dogma was its duty and delight. Then came the materialists. They made us believe our senses and now we doubt our sense. They fed us with facts and we had our fill. Dogma from being a theologic theory became a monopoly of materialism. Now the tables are turned again, and we are ready to admit that the spirits may have done it. The old agnostic alleged that nothing was true till it was proved so. The new one admits everything till it is proved untrue. From denying the probabilities of the universe we have come near to realising its possibilities and admitting them as facts. The comparative values of mental attitudes are hard to compute. It is largely a question of fashion. The ideas of the moment seem the only reasonable ones. This constant change of outlook is part of what we call progress. The race, after long enough, will have looked at everything from every point of view and may then have the beginnings of a true knowledge of the infinite limitations of human thought.

The Ascendancy of the Mediocre.

Medical mediocrity tends to increase. There are several reasons for its doing so, but no justification. By mediocrity we mean an indifferent competence. To be mediocre is not to be average. We must all assume we are average for any given quality till we have been proved otherwise; but we may all refrain from being mediocre. There are four obvious reasons why our profession leans to that fault nowadays. There is the ease of consultation. It is so simple to call in a man to share our responsibility that we are apt to divide our cases into those whose diagnosis and treatment stares us in the face and those which present a little difficulty and send us to consult with the specialist. Then there is knowledge of good things. We get fine results with tried remedies and are satisfied and so become chary of enterprise and avoid new methods because our old ones work "well enough." Then there is success. When that has come, effort is hardly needed. Reputation and a practised urbanity suffice. The busy life has little time for improvement. If the patients are satisfied with the physician, why not the physician with himself? He fulfils the demand and that is enough. These three are mediocrities of quality and affect the general practitioner. One is left for the specialist. His domain is getting narrower each day. As more is to be known about each thing, so the things each man can know are fewer. Our specialist, perfect though he be, has a narrow outlook. That makes for mediocrity, a mediocrity of quantity. This mediocre tyranny is rising up on us. We do not want to be of the elect. The mean is golden and so we do not strive. It is too easy to fulfil a demand and too hard to raise a new standard. As long as we can get along in comfort we are content. Lost ideals are nothing if we have cakes and ale.

The Progress of Biochemistry.

Few of the ancillary medical sciences have shown such activity as organic chemistry. Since the time of Liebig the *rapprochement* between chemistry and biology has been gradually becoming more complete up to the present day. Laboratory investigations have been going on quietly and steadily with a view of elucidating some of those problems of metabolism which possess a practical bearing upon the science of medicine. In the able and instructive address recently delivered by Dr. F. Gowland Hopkins on "The Dynamic Side of Biochemistry," at the Physiological Section of the British Association at Birmingham, the fact was emphasised that the present trend of research lies not so much in the separation and identification of products derived from the animal as with their reactions within the body itself. The biochemistry of the living cell and its relations with its neighbours has long attracted the attention of chemists and biologists alike, and different investigators have approached the subject from widely differing standpoints. It is significant to recall the part played by ferments in general metabolism, and it appears more than ever probable that all metabolic tissue reactions are activated, or catalysed, by enzymes. When one considers that even germs may be trained to perform certain biological functions, such as the splitting of sugars and alcohols, it is at least conceivable that the bioplasm of a body cell should be closely influenced by an enzyme whenever it may have to adjust itself to a new nutritive medium. Whatever be the outcome of modern biochemical researches, one thing is clear, namely, that the physical chemist must continue to play a most important part in the investigation of biological, and therefore of physiological phenomena.

(a) *The Medical Officer,* September 6th, 1913.

Favus and Immigrants.

The recent decision of the Alien Immigration Board in rejecting a married German woman suffering from favus, who had arrived in London with four young children in order to join her husband, a working tailor, in Manchester, raises once more the question of the prevalence of this disease. A few years ago there was quite a number of cases of favus in the East End of London, chiefly among elementary school children, but, thanks to the prompt action of the London County Council in opening a special school for those so affected, the disease was gradually and, it was hoped, finally, stamped out. The difficulty of dealing with favus is two-fold. In the first place, the diagnosis is by no means always obvious, especially if the characteristic lemon-yellow favus-cups, or scutula, and the so-called "mousy odour" are absent. A suspicious patchy baldness, accompanied by slight redness and, perhaps, scaliness, should lead to a further examination by the microscope. In the case referred to, the medical evidence was apparently somewhat conflicting, and had the services of an expert dermatologist been available its true nature might have been revealed sooner. Both favus and ordinary ringworm are notoriously misleading in their clinical aspects, even the most experienced being deceived at times. Then there is the treatment of favus, which often lasts a very long time. It is true that the visible lesions can be speedily cleared up with most parasiticide ointments, but the X-rays are, without doubt, the most potent agent in curing this disease which has been the source of so much trouble and annoyance to immigrants as well as to those whose duty it is to examine and treat them. If it be true, as is alleged, that favus is again on the increase in the East End, the re-opening of the favus centre may be necessary to cope with this pest.

The Royal Society of Medicine.

Members of the medical profession who belong to the Royal Society of Medicine will be looking forward to the opening of the work of the winter session at the Society's fine building at No. 1 Wimpole Street, W. The Section of Obstetrics and Gynæcology, under the presidency of Dr. W. S. A. Griffith, is the first to meet on October 9th, at 8 p.m. The Clinical Section, presided over by Mr. Charters J. Symonds, follows on October 10th with a meeting at 8.30 p.m. In the following week is the meeting of the Section of Surgery, under the presidency of Mr. G. H. Makins, which takes place on October 14th, at 5.30 p.m. Most of the remaining sections resume their work by the end of October, the first ballot for Fellows taking place on October 21st, at 5 p.m. Every facility now exists in the Society's house for the holding of scientific meetings and discussions, the reading of papers and the giving of demonstrations. The latter are now materially aided by the possession by the Society of two epidiascopes, which are capable of projecting solid, opaque bodies upon the screen in natural colours, thus obviating the necessity for diagrams and lantern slides. It is announced that by arrangement with the Secretary, Fellows can have the use of the epidiascopes for private demonstrations. As a place for quiet study and reading, the spacious and well-ventilated library can hardly be excelled. The advantages of Fellowship of the Royal Society of Medicine should appeal to all medical practitioners, whether resident in London or elsewhere, for the Transactions of all the various sections, issued monthly, are worth the subscription alone.

PERSONAL.

Mr. C. G. Haye Sharpe, M.B., Ch.B.Leeds, has been appointed Ophthalmic Surgeon to the Luton Education Committee.

It is announced that Dr. Arthur W. Limont, of Southport, has been invited to become next year's Mayor of that borough.

Dr. Alfred E. Carsberg, M.D.Cantab., has been appointed Physician to the Tuberculin Dispensary, Kennington Road, S.E.

It is announced that Dr. Wilfred Grenfell, C.M.G., of Labrador, is returning to England to deliver some lectures on "Midst Ice and Snow in Labrador."

The Lord Chancellor of Ireland has appointed Dr. Michael J. Kenny, of Bridge House, Tallow, to the Commission of the Peace for the County of Waterford.

Mrs. Alice Stalker, M.B., Ch.B., has been appointed Assistant School Medical Officer and Assistant Tuberculosis Officer to the Wigan Education Authority.

Miss Eva McCall, M.D., Assistant School Medical Officer under the Cambridgeshire County Council, has been appointed School Medical Officer of Jarrow, in succession to Dr. David H. Weir.

An interesting presentation was made the other day to Dr. J. B. Neal, upon his retirement from the post of Medical Superintendent of the St. John's Hill Infirmary, Wandsworth, after over 34 years' service.

Capt. F. W. W. Dawson, R.A.M.C., has been appointed Specialist in the Prevention of Disease, and placed in charge of the Bacteriological Research Laboratory at Brigade Headquarters, Ambala Cantonment.

Dr. F. J. Wethered, M.D., F.R.C.P., will deliver the first Hunterian Society's lecture in the library of St. Bartholomew's Hospital on Wednesday, October 8th, at 9 p.m., on "Fever in Pulmonary Tuberculosis, Its Significance and Therapeutical Indications." The attendance of members of the medical profession is invited.

Dr. John Wood, M.B., Ch.B.Aberd., of the Worcester General Infirmary, has been accepted for foreign missionary service in Calabar, Southern Nigeria, by the United Free Church of Scotland. Dr. Wood goes out as the representative of the Braid U.F. Church congregation, Edinburgh, and he will carry on extensive work at Itu.

CLINICAL LECTURE
ON
THE DIAGNOSIS OF CHRONIC ULCER OF THE STOMACH AND DUODENUM. (*a*)

By JAMES SHERREN, F.R.C.S.,

Surgeon to the London Hospital and to the Poplar Hospital for Accidents.

IN no department of surgery is diagnosis so difficult and treatment in the appropriate cases so satisfactory as that of digestive disorders, considered by the populace, and often by the profession, as "indigestion."

As an example of the mental attitude towards these questions of even the educated public, I would draw your attention to the following, which occurs on page 115 of the Final Report of the Royal Commission on University Education in London :—

"If nine out of ten patients who complain of frequent internal pain are suffering from indigestion, there is a danger of failing to diagnose cancer in the tenth case, and the delay resulting from the mistake may be fatal."

I would impress upon you that indigestion, while a useful term to denote symptoms associated with the ingestion of food, is often a dangerous cloak to hide ignorance. We should never be content until we have arrived at a conclusion as to its cause, remembering that in many instances it is but a danger signal of disease in other organs. Large numbers of patients with cholelithiasis and chronic disease of the appendix are treated medically, labelled dyspepsia, often with disastrous results.

Last week I operated upon two patients with gall-stones—one a man who had attended two large metropolitan hospitals, and had a course of treatment in each for ulcer; the other a woman with a grossly enlarged gall-bladder due to the lodgment of a stone in the ampulla of the cystic duct, who had been treated both in this country and in Germany as "nervous" dyspepsia. It has been my experience that "nervous" dyspepsia in the male is usually synonymous with chronic duodenal ulcer.

I would put forward the thesis that every case of painful indigestion should be regarded surgically. A large percentage of them are capable of cure by operation at an almost negligible risk when compared with the serious nature of the disease producing the symptoms.

I do not intend to discuss cases of pyloric stenosis either of the so-called congenital type—the best name for which is infantile pyloric stenosis—or that form met with in adults, due in 90 per cent. to the cicatrisation of a chronic ulcer of the first part of the duodenum.

The symptom common to all the cases under discussion is discomfort or pain. I would draw your attention first to points of importance in connection with this. The pain is felt at or above the umbilicus—its exact seat, right, left, upper or lower epigastric, should be noted. You should remember that left-sided pain is suggestive of gall-stones and gastric ulcer; right, of chronic duodenal ulcer. The nature of the pain must be elicited, whether a discomfort or real pain, whether associated with flatulence or not. Discomfort due to flatulence, a "stuffy" pain which many patients describe, should direct attention to the gall-bladder and ileocæcal region. "Wind" pains, if severe, are in many cases of biliary origin.

"Cramping" pains also own this cause, and are also associated with chronic duodenal ulcer and pyloric spasm.

Inquire as to the exact time of appearance of the pain and its regularity. Pain appearing at the same time day after day is a symptom of great importance in the diagnosis of chronic gastric and duodenal ulcers. Irregularity in its time of appearance—immediately after a meal at one time, during it on another occasion, an hour after on yet another—suggests gall-stones or chronic disease of the appendix. Night pain is of importance; when waking the patient between 1 and 2 a.m. regularly it is a characteristic symptom of chronic duodenal ulcer. It also occurs occasionally in chronic gastric ulcer when involving the pancreas, and in certain cases of right renal disease which may give symptoms simulating duodenal ulcer. Irregular pain at this time is a common symptom of gall-stones; thus in 70 cases with colic in whom I made definite inquiry with regard to this point 54 had had pain at night, 19 only at night, and in addition in five only rarely in the day-time.

The next important point is the relation of pain to taking food. Pain appearing at a definite regular time with a well-marked latent period is usually due to ulcer, if relieved by the next meal—duodenal ulcer. Occasionally in chronic gastric ulcer, if this is associated with an excess of acid or the ulcer is adherent to the pancreas, the pain is relieved temporarily by warm milk or sodii bicarb., but the permanent relief of the next *meal* is not present. Its association with vomiting and its immediate relief when the stomach is empty—the spontaneous vomiting of gastric ulcer, the urgent retching and frequent useless vomiting of biliary colic, the vomiting often self-induced in duodenal ulcer, are points which must be taken into consideration.

In a few cases of duodenal ulcer vomiting suggestive of the vomiting of biliary colic may occur, due, I believe, to pyloric spasm.

I have left until last the most important point in the diagnosis, the presence of *attacks*. By this I mean that for a period of time, a week or perhaps a month, the patient suffers regularly day after day from certain symptoms, followed by an interval of perfect or almost perfect digestive health. Unless pain of this character is present, you should hesitate before diagnosing chronic gastric or duodenal ulcer.

Pain present after a meal one day, waking the patient at night perhaps a week later, and so on, is a characteristic of gall-stones. Pain or discomfort, rarely absent, present day after day in varying degree is a character of the gastric disturbance associated with chronic appendicitis and chronic constipation.

Chronic gastric and duodenal ulcer must be diagnosed from malignant disease of the stomach and elsewhere in the abdomen, and from extra gastric disease such as gall-stones and chronic appendicitis, intestinal stasis, nervous diseases, urinary disease.

In every patient, not only must the alimentary system be investigated, but the whole body. The

---

(*a*) Delivered at the London Hospital, June 20th, 1913.

nervous system must not be neglected, the urine tested and rectal examination made. The importance of the latter in both sexes is great.

I may quote the following as examples.

A patient of 59 was sent to me in May, 1912, as carcinoma of the stomach. He had had indigestion off and on for several years, but for the preceding twelve months had had it each day, slight epigastric pain one to two hours after food, without vomiting. A test meal showed absence of free HCl with a total acidity 23. On examination I found that his bladder was distended, due to an adenomatous enlargement of the prostate.

In another case a woman sent to me for the surgical treatment of her indigestion; rectal examination revealed a left pyosalpinx adherent to the sigmoid.

The gastric symptoms associated with diabetes and phthisis are more suggestive of those met with in chronic appendicitis or carcinoma of the stomach than chronic ulcer.

Before passing to the question of diagnosis it is well to have a clear idea of what may be considered the typical symptoms of ulcer. Our conception of these has entirely changed in the past few years. As a student, my ideal gastric ulcer patient was an anæmic girl of 20, with pain after food, vomiting, and hæmatemesis. Duodenal ulcer was looked on as a rare event, only diagnosable by hæmorrhage or perforation. We now know that chronic ulcers of the stomach or duodenum are diseases most often met with in the male sex between the ages of 30 and 50. Chronic duodenal eight times, chronic gastric three times as frequently in men as in women. In 160 cases of unperforated chronic duodenal ulcer operated upon to the beginning of June, 1913, only 21 were women; of 151 chronic gastric, 56 were women.

Pain is the most prominent symptom. Its striking feature is its occurrence in "attacks," intermitting with periods of perfect or almost perfect digestive health. In patients with chronic duodenal ulcer symptoms are more common in the winter time, and may be brought on by cold or wet.

In chronic gastric ulcer pain is closely associated with the ingestion of food, usually coming on within an hour, but there is always a definite latent period and the time of its onset is constant—it does not vary from meal to meal or day to day. This is of great importance in the diagnosis from appendix dyspepsia and intestinal stasis in which the pain may appear during or immediately after taking food on one day, the next perhaps one to two hours after.

Night pain is unusual; it occurred in 26 out of 130 in whom I made inquiry. In these cases the ulcer was on the posterior surface of the stomach and involved the pancreas.

Vomiting is generally present at some time during the course of the disease, but is often infrequent, and many cases come to operation without its occurrence. If stenosis is present, either at the pylorus or in the body of the stomach, vomiting is invariable.

Hæmatemesis in quantity that can be recognised by the naked eye is unusual; when it occurs it is a complication of the utmost gravity, demanding operation as soon as possible.

Examination of the gastric contents after a test-meal shows a slight increase in acidity or one little removed from normal, unless hour-glass contraction has taken place, when it is usually diminished and free HCl often absent.

Although chronic gastric ulcer is more common among men, hour-glass stomach is more frequently met with in women. I have operated on 19 patients with hour-glass stomach, only four of whom were males. There is nothing in the history diagnostic of this condition. In many instances the most suggestive feature is the continuance of the symptoms; after many years of intermittent dyspepsia the symptoms persist, and it is this that brings the patient under the care of the surgeon, often sent as malignant disease. On palpating the abdomen in patients with hour-glass stomach I have often been able to feel peristalsis in a cardiac pouch and to appreciate that the contraction of this part of the stomach was associated with gurgling, as fluid was passed through the strait connecting the two pouches.

I have notes of the test-meals in 13 of these cases; in all except two there was a marked diminution in acidity, and in seven free HCl was absent. In the two with no diminution both were males, and in neither was the increase great—free HCl .13 and .14, with a total acidity of 57 and 64.

Chronic duodenal ulcer.—Undoubtedly, as insisted upon by Moynihan, the majority of cases present symptoms so definite that a diagnosis can be made with certainty. Among my 160 cases 123 were of this type. Of the remainder, difficulties arose in the diagnosis from gall-stones and from gastric ulcer.

Pain is the most characteristic feature; at first it amounts only to a sense of uneasiness or a feeling of distension about two hours after food, relieved by the next meal, waking the patient between 1 and 2 a.m. This is the hunger pain of Moynihan. Night pain is rarely absent. I have definite notes on this in 146 cases; it was absent in 20 only.

Remission of symptoms is most important in diagnosis; if there is no remission there is no ulcer. Between the attacks the patient is in perfect health. Worry, cold, over-work may all bring on an attack.

Spontaneous vomiting is unusual, but self-induced vomiting—rare in gastric ulcer—is often a characteristic feature.

Pain may be absent in the late stages of the disease when pyloric obstruction has led to gastric dilatation, although the ulcer is still unhealed.

I have come across several cases in which there has been a complete absence of pain throughout the whole course of the disease, the symptoms consisting of attacks of dilated stomach vomiting with intervals of perfect health.

It has been stated that a chronic duodenal ulcer may be latent, giving evidence of its existence first by perforation or hæmorrhage. This is unusual. In ten cases operated upon for severe melæna, all gave a long standing history typical of the condition. Among 30 cases of perforation, in five no previous history could be obtained, but two of these were acute ulcers.

Examination of the gastric contents after a test-meal may be of great help in diagnosis. Unless complicated by secondary gastric dilatation or recent hæmorrhage, there is an excess of free HCl and the total acidity is high. In those cases in which the symptoms due to gall-stones or disease in the ileo-cæcal region mimic those of duodenal ulcer, the reverse usually obtains.

The ordinary physical examination of the patient is often entirely negative, particularly in chronic duodenal ulcer.

It is well after taking the history to carry out the examination in a routine manner. The general appearance of the patient should first receive attention, but remember that the so-called dyspeptic looking individual is not the type in whom organic stomach disease is found. Unless hæmatemesis or severe vomiting has occurred, they are often healthy looking individuals.

The condition of the teeth must be next investigated, remembering that tooth plates often conceal a multitude of septic stumps.

The whole abdomen should then be inspected in a good light, looking for the narrow upper abdomen of visceroptosis, swellings, visible peristalsis, etc.; then palpation at first general, noting the degree of rigidity or tenderness; then local, first in the epigastric region. Careful coaxing here will often cause a contraction of the cardiac pouch of an hour-glass stomach or an early gastric dilatation that can be felt. Then the examination should be continued on the right side, searching for swellings and tenderness under the ribs and the presence of movable kidney. Tenderness in right iliac region should be noted as indicating possible disease in the ileo-cæcal region. Finally, a careful rectal examination should be made and the urine examined.

The condition of the heart, lungs, and nervous system must never be neglected.

This examination taken with the history will usually lead to the case being put into one of two groups; either it is a definite case of chronic gastric or duodenal ulcer or gall-stones or it is indeterminate, of the gall-stone-duodenal type, or the appendix-intestinal stasis and gastric ulcer.

Typical cases of duodenal ulcer, gastric ulcer, gall-stones are obvious, and further investigation, although interesting, does not give more help. This applies to 75 per cent. of cases of chronic duodenal and about 40 per cent. of cases of chronic gastric ulcer.

Where there is doubt further investigation should be carried out, even although it is obvious that the case is one for surgical intervention. Every endeavour should be made to come to a diagnosis before exploring the abdomen. I believe this is important not only from the point of view of the initial incision and strength of abdominal wall, but for quickness of operating and avoidance of unnecessary abdominal manipulation—points of the utmost importance in a speedy convalescence. It should be our endeavour to deal with the disease through as small an incision as is compatible with thorough work.

There are four special methods of examination which must be discussed:—

1. Direct of the stomach.
2. Inflation.
3. X-ray after a bismuth meal.
4. Examination of gastric contents after a test-meal.

With regard to direct examination of the stomach, in an address on carcinoma of the stomach given two years ago I used these words: "You may be surprised that I have not mentioned the gastroscope as a diagnostic instrument. In its present form its use is probably more dangerous than exploratory laparotomy (*a*) in the hands of a competent surgeon. It is difficult if not impossible, to see the whole of the stomach; other parts of the intestinal canal and other viscera cannot be investigated."

This opinion I still hold, although the direct vision gastroscope of Hill-Herschell is a less dangerous instrument than the old indirect one.

With regard to inflation of the stomach. This is a mode of investigation that I believe is of little help in diagnosis, and one which should certainly not become routine. The size of the stomach is of no moment, providing it is carrying out its work efficiently. Early organic obstruction cannot be recognised by this means. It is useful for demonstration purposes, and very occasionally an hour-glass stomach may become evident.

X-ray examination of the stomach after bismuth meals is disappointing from the point of view of differential diagnosis. It, of course, gives evidence of organic obstruction, also of gastroptosis and many cases of hour-glass stomach. But these are not the cases in which help is needed.

In chronic duodenal ulcer the stomach usually empties itself very rapidly indeed, with vigorous contractions of the pyloric end of the stomach; the same is often noted in chronic gastric ulcer with, in addition, if the ulcer is situated on the lesser curvature, often spasmodic hour-glass stomach.

In twenty consecutive cases of chronic duodenal ulcer without stenosis, in fourteen vigorous contractions of the pyloric end of the stomach with rapid emptying were noted "suggestive of ulcer." In one an hour-glass stomach was diagnosed; in five nothing abnormal was noted. In thirteen cases of chronic gastric ulcer without stenosis, vigorous contractions suggestive of ulcer were noticed in eight; in the remainder nothing abnormal was noted.

These vigorous contractions of the pyloric end of the stomach are by no means confined to cases of chronic ulcer of the stomach and duodenum. In seven consecutive cases of gall-stones, vigorous contractions suggestive of ulcer were seen in five. These were all cases in which free HCl was present—in three of them in excess. In the cases in which nothing abnormal was noted free HCl was absent. It is in the cases in which there is a high acidity that help is needed in the diagnosis, but these are just those in which this method gives no aid.

Again, in the dyspepsia associated with chronic appendicular disease, in several cases vigorous contractions suggestive of ulcer were noted.

With regard to the diagnosis of hour-glass stomach, in five consecutive cases this was made correctly in four. On the other hand, in a case of gall-stones and one of chronic appendicitis, this diagnosis was erroneously suggested.

I have excluded the cases in which clinically a stenosis was present either in the first part of the duodenum or at the pylorus producing a dilated stomach, or in the body producing hour-glass stomach detected by other means.

In conclusion, it has been my experience that the information obtained by X-ray examination after a bismuth meal is at present of no aid in diagnosis. In all the cases in which there was any doubt from the clinical findings, no help whatever was given by this method of investigation.

With regard to the X-ray diagnosis of hour-glass stomach. In the majority of cases in which an hour-glass contraction of the stomach is seen it is not of organic nature, but occurs in such various conditions as gall-stones, chronic appendicitis, duodenal ulcer, lesser curvature ulcer. In organic hour-glass stomach the lower pouch is often very difficult to make out. At the first examination the gastric contents appear to be held up at its cardiac end; if examined five or six hours later a second pouch will often become visible with sometimes a trickle of bismuth between.

Test-meals.—The results of this method of examination are very helpful, particularly in the diagnosis between duodenal ulcer and gall-stones, chronic gastric ulcer, and appendicular disease. If gastric stasis is suspected, a stomach-tube should first be passed to see if there is any residue; if there is, the stomach should be washed out before giving the test-meal.

All the results have been worked out by Drs. Paton and Tidy in the Clinical Laboratory. They

---

(*a*) *British Medical Journal*, June 24th, 1911.

have published an account of of their methods. *(a)* The test-meals consist of two large cups of tea, with milk and sugar if desired, and two pieces of toast lightly buttered. The gastric contents are withdrawn in an hour.

I now wish briefly to discuss the points in the diagnosis from malignant disease of the stomach, gall-stones, chronic appendicitis, chronic constipation, urinary diseases.

It is rarely that the diagnosis between chronic gastric ulcer and carcinoma has to be made. Carcinoma in its early stages, unless it attacks the orifices producing mechanical obstruction, resembles more the gastric disturbance associated with gall-stones and chronic appendicitis. Many more cases of this nature are erroneously diagnosed as carcinoma than chronic ulcers.

There is, however, one complication of chronic gastric ulcer which in its symptoms mimics carcinoma; that is hour-glass stomach.

Cases of carcinoma of the stomach may be divided into three groups:—(1) Following previous gastric disease; (2) primary; (3) latent.

It is in the first group that the difficulty arises. After several "attacks" of gastric ulcer one occurs after which the symptoms remain day after day. This is also met with in hour-glass stomach. In this group of cases X-ray examination after a bismuth meal and the result of a test-meal may enable the diagnosis to be made. In cases of carcinoma secondary to gastric ulcer, free HCl is usually present and the total acidity is about normal. In hour-glass stomach free HCl is often absent and the total acidity low.

In carcinoma developing in a previously healthy stomach the symptoms are insidious, but rarely suggest those of chronic ulcer. In this group free HCl is usually absent and the total acidity is low; occasionally the gastric dilatation resulting from the scarring of an old duodenal ulcer may raise a suspicion of malignant disease. This will nearly always be dispelled by a careful history.

The greatest difficulty rises in the diagnosis between gall-stones and duodenal and chronic gastric ulcer. Here the *greatest* help is obtained from the history. The points to be remembered are the irregularity of the pain and the frequency of night attacks in gall-stones. If vomiting is present it is usually accompanied by much retching, and brings no relief. As previously pointed out, free HCl is often absent and total acidity low.

In the dyspepsia associated with chronic disease of the appendix, the symptoms may mimic either gastric or duodenal ulcer, but the clear-cut course is absent. Pain is usually felt in the epigastrium, occurring sometimes in irregular attacks, at others being present nearly every day. It bears no regular definite relation to food being felt for example an hour after one meal, immediately after or even during another. It may be referred to the right iliac fossa where tenderness may be present, the pain on pressure being appreciated in the epigastric region. Nausea is frequent but vomiting uncommon, although hæmatemasis may occur. The condition is confined to no age (youngest 18, oldest 67) but most of my patients were between the age of 30 and 40. The sex distribution differs little from that of other types of appendicular disease. Several of the older ones were sent to me as carcinoma of the stomach.

A test-meal is often an aid. As a rule, acidity is low, and frequently there is an absence of free HCl, which is extremely suggestive. Thus among 39 consecutive cases in which test-meals were given, acidity free and total was diminished in 21, free HCl was absent in 15 of these, normal in seven, a little raised in 11, but only in two was it high. One free HCl .22, total acidity 84, the other free HCl .30, total acidity 93.

The type of appendix found in this disease is interesting. In 63 patients upon whom I operated for appendicular dyspepsia, in 49 the appendix was of the obliterative type, often being very adherent.

The dyspepsia associated with chronic constipation may mimic very closely that of chronic appendicitis. Unlike the latter, however, it is more common in women, and is usually associated with a frequent or constant pain in the right iliac fossa. The test-meals show the same low acidity.

In chronic appendicitis removal of the appendix alone effects a cure; in chronic constipation (intestinal stasis), often associated with gastroptosis, ileal kink, Jackson's membrane, regulating the bowels and wearing an abdominal belt will make the patient comfortable in many cases. If operation is necessary, then not only must the appendix be removed, but the ileal kink should be dealt with and sometimes the cæcum or ascending colon removed and the end of the ileum implanted into the transverse colon. I look on ileo-sigmoidostomy alone as a procedure followed by little permanent benefit, and often bringing in its train fresh complications.

I must now pass on to what may seem to you to be somewhat far-fetched and little likely to arise in actual practice; that is the diagnosis between gastric and duodenal ulcer and urinary disease. It is impossible to lay down any certain rules, but it is a subject to bear in mind.

I have already alluded to one case in which the symptoms were due to enlarged prostate, of which the patient was unaware. This belongs to the group described by Rosenheim as "uro-kinetic dyspepsia." I would remind you that mucous ulcers of the duodenum may complicate infections of the urinary tract.

There is yet another group in which the pain of surgical renal disease simulates that of gastric disease, or in which gastric disease is diagnosed by competent physicians as renal disease.

I have two patients in hospital at the present time, both seen by eminent physicians, and thought to be suffering from left renal colic. In the one I found a chronic duodenal ulcer; in the other, in which the symptoms mimicked left renal colic even to the pain shooting into the testicle, there was an indurated ulcer high up on the posterior wall of the stomach, which had perforated, and was adherent to the pancreas. I removed it by transgastric excision. I have known the pain in other cases of posterior ulcer adherent to the pancreas radiate to the testis.

Until a few weeks ago I was unaware that the presence of a stone in the pelvis of the kidney would cause symptoms closely resembling those of chronic duodenal ulcer.

I have under my care now two patients in both of whom pain was felt at 10.30 a.m. and 4 p.m., relieved by food; it woke them in the early hours of the morning, but—and this is important—from the time of its onset there were no free intervals; the pain continued day after day. In one patient there was nothing to suggest kidney, and in the other there had been in addition two attacks of renal colic.

In this group, as in the others, the symptoms of gastric or duodenal ulcer are never absolutely copied.

As a rule, the pain is lateral in the abdomen. Although in the two cases referred to it was on the right side of the abdomen on a level with the umbilicus, but, as one patient said, "struck" through to the back. In these, as in all the anomalous cases, every method of examination must be tried, and only rarely will this fail.

(a) *Quarterly Journal of Medicine*, July, 1911. Vol. 4. No. 16.

In conclusion, I would add that careful attention to the history and a thorough examination will lead to the correct diagnosis in most cases; in a few, examination even by the most "modern" method will fail to enable us to arrive at a conclusion. But if care is taken, although an exact diagnosis is not made, yet it can be confidently stated that the symptoms are the result of one of two causes, which can only be efficiently and safely treated by operation.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Professor V. Hutinel, Professor in the Clinique of Diseases of Children, Paris Faculty of Medicine. Subject: "Occurrence of Meningeal Reactions in the Course of Poliomyelitis."*

ORIGINAL PAPERS.

X-RAYS IN THE DIAGNOSIS OF ABNORMALITIES IN THE INTESTINAL TRACT.

By MAURICE R. J. HAYES, F.R.C.S.I.
Radiologist, Mater Misericordiæ Hospital, Dublin.

So much has been written recently on the subject of intestinal stasis, and the X-rays have assisted so materially in the recognition of this condition, that a contribution on the subject with which I am about to deal may be of interest.

In a paper on "X-Rays in the Diagnosis of Urinary Calculi" (Medical Press and Circular, January 4th, 1911), I stated that "Radiography should be employed as an aid to, and not a substitute for, the ordinary methods of diagnosis. The X-ray has proved to be such a 'short-cut' in the diagnosis of so many conditions, and it has relieved us so much of the necessity of making a careful analytical study of symptoms and signs, that we are becoming more and more inclined to resort to it to the exclusion of other trustworthy methods of clinical investigation."

That statement will bear repetition here. More especially at the present moment, when new territory is being explored, is it necessary to record carefully our observations, and, if at all possible, to check our findings at the subsequent operation.

The positions which the different parts of the intestinal tract occupy within the abdomen are so varied even in the same types of individuals, and in the erect and prone positions, that it is difficult to fix within narrow limits the "normal" sites of the stomach and the large intestine.

To interpret accurately the various shadows produced by the intestines when loaded with an opaque substance is not at all an easy matter, and in viewing the radiogram it must not be forgotten that we are looking at the shadow cast by the object and not the object itself; secondly, that the shadow of a loop of intestine when viewed obliquely gives the idea that the bowel is acutely kinked when in reality the curve may be the arc of a circle which may not be at all sufficient to cause delay to the passage of the intestinal contents. To this I shall refer later.

To examine the œsophagus, cachets containing 10 to 15 grains of bismuth carb. may be given, or the bismuth carb. may be mixed with milk and sago, arrowroot, or bread crumbs—2 oz. to 4 oz. of the carbonate to a pint of the vehicle may constitute a meal.

The Œsophagus in its cervical part may be studied by viewing it from one or other side of the neck. Before dealing with strictures I will refer briefly to two cases of diverticulum of the œsophagus which I have seen. Both patients were men, one aged 58 and the other 60.

In each the history and symptoms were typical of the condition. By pressing on the left side of the neck a considerable amount of mucus mixed with food was ejected into the mouth—a necessary procedure to begin with. With the fluorescent screen the bismuth food was seen to pass at first downwards and backwards towards the vertebral column, and then downwards and towards the right side into a sack which filled as more food was swallowed.

As the pouch became more distended a sense of discomfort was experienced, and each patient was conscious of the fact—which could be observed on the screen—that no food passed into the stomach. With each succeeding attempt to swallow, the shadow was seen to rise and fall, and sometimes the bismuth food regurgitated into the mouth. In each case when the pouch had filled none of the bismuth passed down the œsophagus, obstruction being due to pressure of the pouch. When, however, these patients were free to incline the head and neck forwards towards the right a sensation of relief was experienced, and portion of the bolus passed into the stomach.

One of these men was again radiographed four days after the first examination, when the pouch could be seen as clearly as if he had just then swallowed the bismuth, although none of the latter had been given in the interval. Fig. 1.

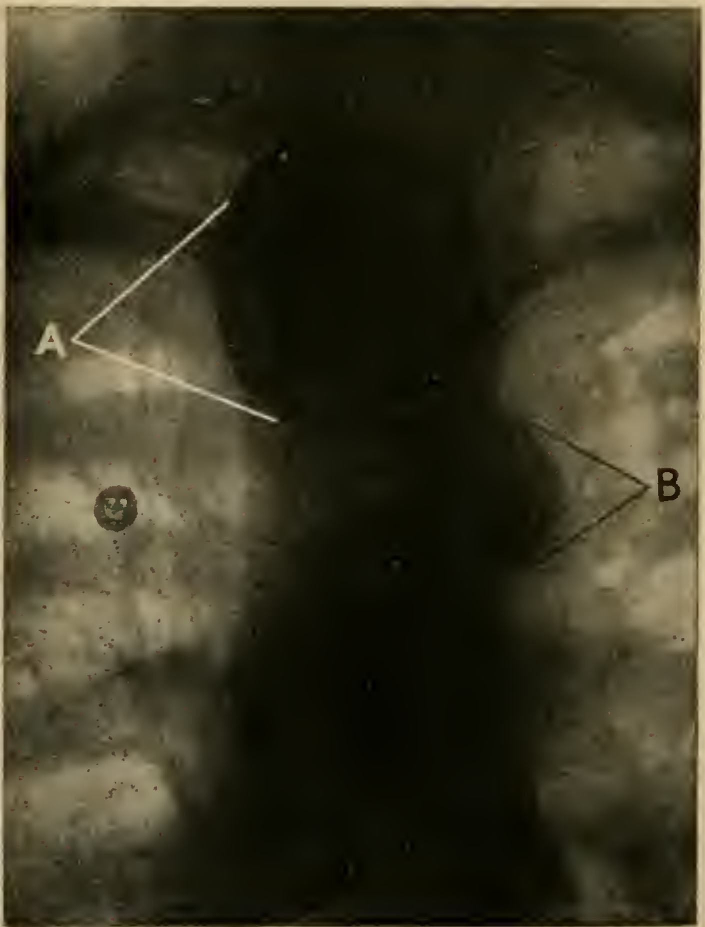

Fig. 1.—A. Diverticulum. B. Left lateral aortic bulge.

The intra-thoracic portion of the œsophagus in its whole extent can be examined by viewing the chest obliquely from the right side in front (right anterior oblique position) or from the left side behind (left posterior oblique position).

Obstruction to the free passage of food through the œsophagus may be caused also by the pressure of tumours, aneurysms, or a generally dilated aorta.

The cause of the obstruction may be readily detected by screen examination, but that a generally dilated aorta may produce symptoms of obstruction which suggest the presence of cancer is a fact that is sometimes forgotten.

Strictures of the œsophagus may be spasmodic, cicatricial, or malignant. Each variety has special X-ray characteristics. *Spasmodic strictures* usually occur near the cardiac end of the tube. The food passes normally downwards in an elongated oval mass, having a rounded head and a tapering tail. There is usually some dilatation above the contraction, but no food passes into the stomach. As more food is swallowed the size of the shadow increases and the peristaltic movements become more violent until after a few minutes the spasm relaxes and the contents enter the stomach with a sudden rush. Sometimes the food is retained in the œsophagus for a considerable period, and there may be an inclination to regurgitate it; but these patients rarely vomit, and they can tell you when the food has passed onwards.

In *cicatricial contraction* the antecedent history aids in the diagnosis. There may be seen on the screen one or more situations where some narrowing of the lumen exists, but the greatest narrowing is again just above the diaphragm. In these cases there is not as a rule complete hindrance to the passage of the food, which latter may be observed to trickle through in a narrow stream. Here again the œsophagus is dilated above the site of the stricture, but peristaltic movements are more active and violent, and as contraction follows contraction the contents sometimes rise as high as the arch of the aorta, or there may be regurgitation. These violent peristaltic movements are very typical of cicatricial stenosis, and once seen they are not soon forgotten. There is never a sudden emptying of the food into the stomach as occurs in the œsophagismus.

Malignant strictures are most commonly met with in men. The usual situation is near the cardiac end, but they frequently occur in the neighbourhood of the level of the bifurcation of the trachea. Many dark shadows may be observed along the line of the œsophagus, which are produced by the malignant lymphatic glands.

In cancer of the œsophagus the food passes normally until it reaches the site of the stricture, through which, as in the preceding variety, it may pass in a thin stream, or there may be complete occlusion of the canal.

Some dilatation always exists just above the site of the stricture, but peristaltic movements are absent or very feeble until the œsophagus is filled for some distance above the stricture. In malignant cases it is usual to find reverse peristalsis, and the food is not retained very long.

The feeble peristaltic movements are possibly due to the pathological changes occurring in the œsophagus, and the reverse peristaltic waves are caused reflexly by the food coming in contact with the ulcerated surface of the new growth. Owing to the emaciated condition of patients suffering from cancer of the gullet, it is easy to examine them with the X-ray.

The Stomach.—The position of the stomach varies when viewed in the erect and recumbent postures. When standing, the stomach assumes a vertical position in the left side of the abdomen, and the lesser curvature in its upper two-thirds forms a straight line which is almost parallel to and about 1½ inches to the left of the vertebral column, being a little nearer to it below than above. The pyloric portion then curves somewhat abruptly towards the middle line in the region of the umbilicus.

The cardiac portion, which is filled with gas, can be outlined as a clear space beneath the left arch of the diaphragm.

The greater curvature extends to a line drawn transversely between the summits of the iliac crests, the lesser curvature being from 1½ to 2 inches higher.

The pylorus is most frequently found about 2 inches above and to the right of the umbilicus.

In the recumbent position the stomach is mainly horizontal—the shadow at the cardiac ends broadens as most of the food gravitates into this portion, and there is a corresponding diminution in the size of the pyloric part of the stomach.

The greater curvature lies from 2 to 3 inches above the umbilicus. When one considers the numerous factors which may without giving rise to symptoms cause innumerable alterations in the shape of a flaccid organ like the stomach, the difficulty of easily detecting changes of a pathological nature can be readily understood. It is necessary to allude only to a few—*e.g.*, indiscretion in the selection of diet, overloading, loss of tone in the abdominal muscles, repeated pregnancies and tight lacing in women.

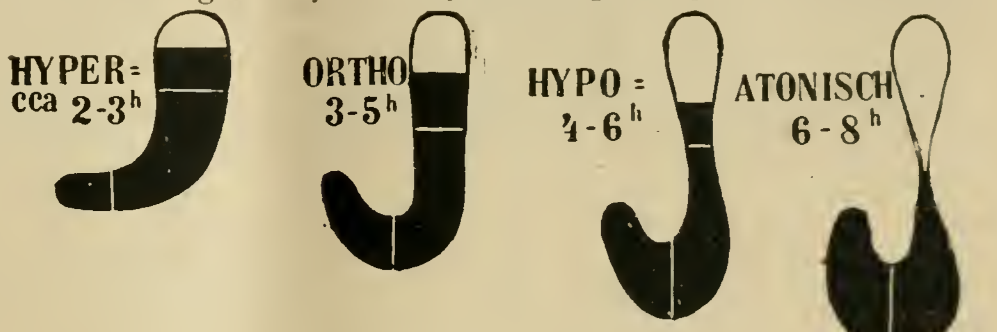

Fig. 2.

Fig. 2, after Holzknecht, shows four types of normal stomach. "Schlesinger, following Groedel's suggestion, has shown that these variations in form are simply due to differences in the habitual tone of the musculature. He names the four forms —hypertonic, orthotonic, hypotonic, and atonic." Holzknecht has never seen the hypertonic form in women, and he says: "We may consider one, two, three the typical forms for men, and two, three, four as the normal forms for women." ("Archives of the Röntgen Ray," July, 1912, pp. 61 and 62.)

The hypertonic form is not often met with. I have seen it on a few occasions only, and these were the rare instances in which the greater curvature of the stomach was situate at a higher level than the umbilicus when the patient was examined in the erect position.

Gastroptosis.—In determining the degree of this condition it would be advisable to be guided by permanent landmarks rather than by the umbilicus, which, though convenient, varies in position. It would be better, therefore, to take our measurements from a line drawn between the summits of the crests of the ilia. In the erect position the greater curvature of what may be regarded as the normal stomach extends to this line, and the degree of ptosis can be estimated by measuring the distance below this to which the greater curvature drops.

The dropped stomach is for the most part vertical in position and generally dilated and hypotonic. The cardiac end is elongated and tubular in appearance, and in those cases where the plyorus is not displaced the descent of the stomach would appear to be due to loss of muscular tone not only in the stomach, but in the abdominal muscles also. In extreme cases of gastroptosis the greater curvature may be found at the symphysis pubis. I shall show you a photograph of one such case, and yet this lady had no gastric symptoms. Fig. 3.

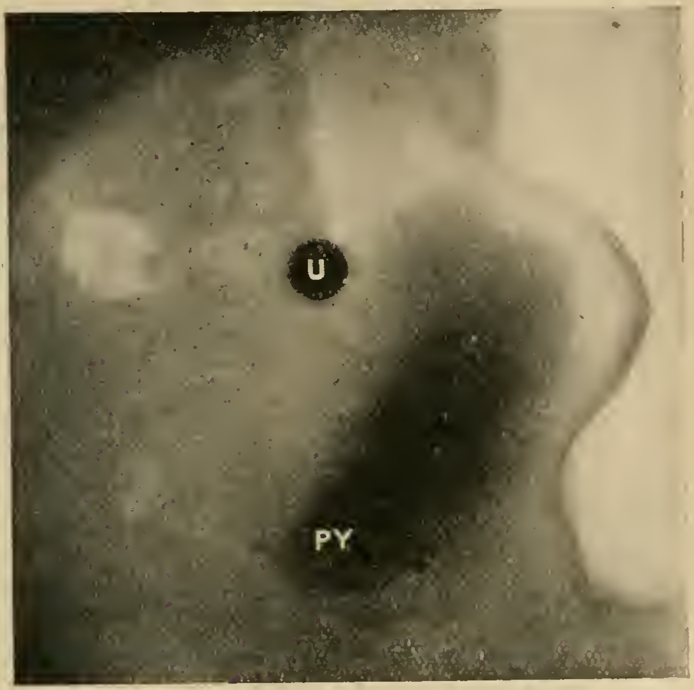

FIG. 3.—PY. Pyloric part of stomach. U. Umbilicus.

It has been contended by many that what have been radiographically diagnosed as "dropped stomachs" are not in reality such at all, and they say that the downward displacement of the organ is due to the weight of the ingested bismuth salt. To dispose of such a fallacious argument as this it is only necessary to point out that the first morsels of the food descend to the lowest level of the stomach, and that the entire amount which is subsequently swallowed does not make the greater curvature descend to any appreciable extent.

Ulcers of the Stomach.—It will be convenient to consider non-malignant and malignant ulcers together. It is possible to recognise large ulcers, especially if they be situate along the curvatures. Associated with them is spasm of the muscle, which produces an hour-glass-like appearance, and normal peristaltic movements are interfered with. When the contents have left the stomach a good photograph may show a thick shadow of bismuth adherent to the surface of the ulcer.

It is also said that the exact site of the ulcer can be localised by palpating the site of maximum tenderness. With this latter statement I am not in concord, and I regard it as a very unreliable sign. I will throw on the screen a slide the subject of which had this symptom. The general appearance and behaviour of the stomach strongly suggested the presence of an ulcer, yet at the operation no ulcer was found. In my experience a point of maximum tenderness to pressure over the stomach or duodenum cannot be regarded as strong presumptive evidence of the presence of an ulcer. I have frequently found it where no ulcer was discovered at the subsequent operation, and here again I would remind you that it is only comparatively recently that X-rays have been employed in the diagnosis of pathological conditions of the stomach, and although much laborious work has been done and carefully recorded, and a great deal of valuable information gained, the time has not yet arrived when accurate deductions can be drawn from all the various appearances which are to be observed on the screen or on the negative.

Hour-glass Stomach.—In the recognition of this condition there is no doubt that the X-ray is the most accurate diagnostic agent at our disposal. The patient must be examined in the erect and recumbent positions, and the condition must be carefully differentiated from hour-glass appearances which are produced by spasmodic contraction of the "mid-gastric sphincter," which latter relaxes after some minutes or may disappear on massaging the stomach.

As the bismuth food enters the stomach it does not pass beyond the constriction, and the cardiac portion assumes the appearance of an inverted cone. According to the degree of narrowing, much or little food may pass into the pyloric portion immediately.

In the recumbent posture the constriction is more evident, and the food may be seen passing through the narrow isthmus, the borders of which may present a jagged outline.

On examining the patient, within two or three hours the food will be seen in the pyloric part of the stomach, and the cardiac part may be empty.

On the skiagrams which I will show you these details can be seen. The second was taken five hours after the first. All the bismuth food had left the cardiac portion, and the pyloric portion still contains a large amount. Figs. 4 and 5.

The duodenum varies considerably in size, but its situation is almost constant. It is not unusual to find a kink at the duodeno-jejunal junction, which obstructs the free passage of the intestinal content. This kink is produced by the sudden descent of the jejunum, and as it may disappear when the patient lies down it is likely to escape detection at operation. In these cases the duodenum is very much enlarged, and peristaltic movements are extremely active. With each succeeding contraction the bismuth food can be seen to be violently driven on-

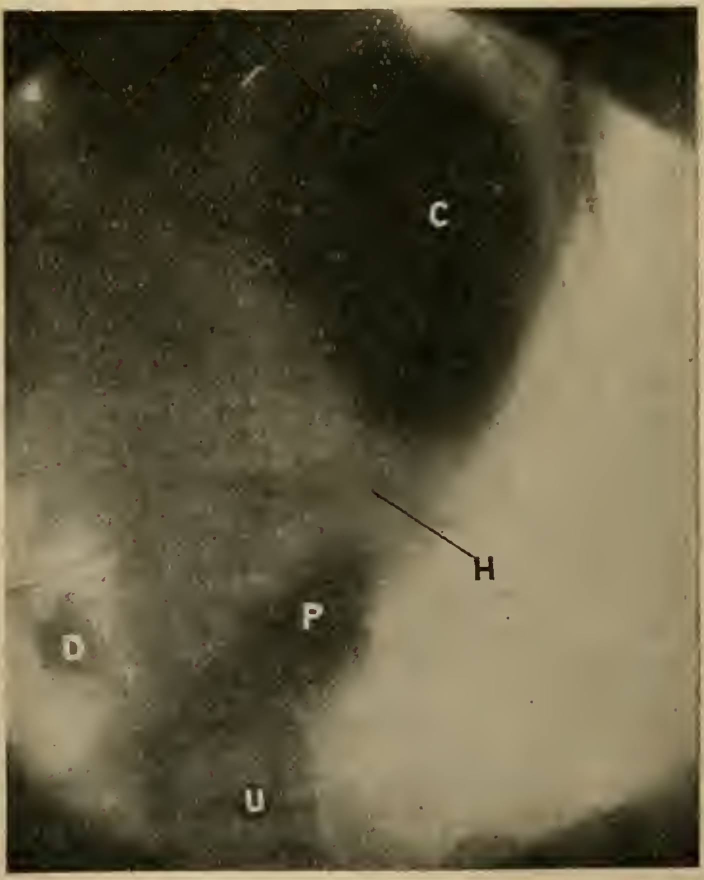

FIG. 4.—Hour-glass stomach ten minutes after a bismuth meal. C. and P. Cardiac and pyloric portions of stomach. D. Duodenum. H. Hour-glass constriction. U. Umbilicus.

wards to return in an axial stream which simulates reverse peristalsis.

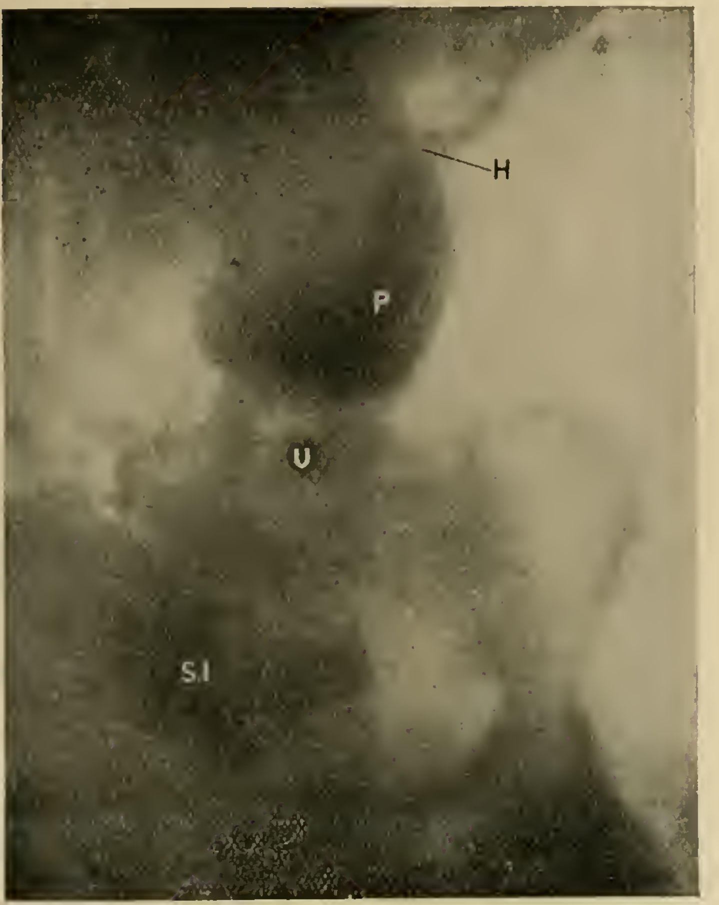

Fig. 5.—From same patient as Fig. 4, five hours after bismuth meal. H Hour-glass constriction. P. Pyloric part of stomach. S.I. Small intestine. U. Umbilicus.

I will show you photographs of such a condition from a young man, aged 23, in whom the diagnosis of duodenal ulcer had been made by a competent clinician. The X-ray examination showed the duodenum as above described, and demonstrated in addition a terminal ileal kink, both of which were verified at the subsequent operation.

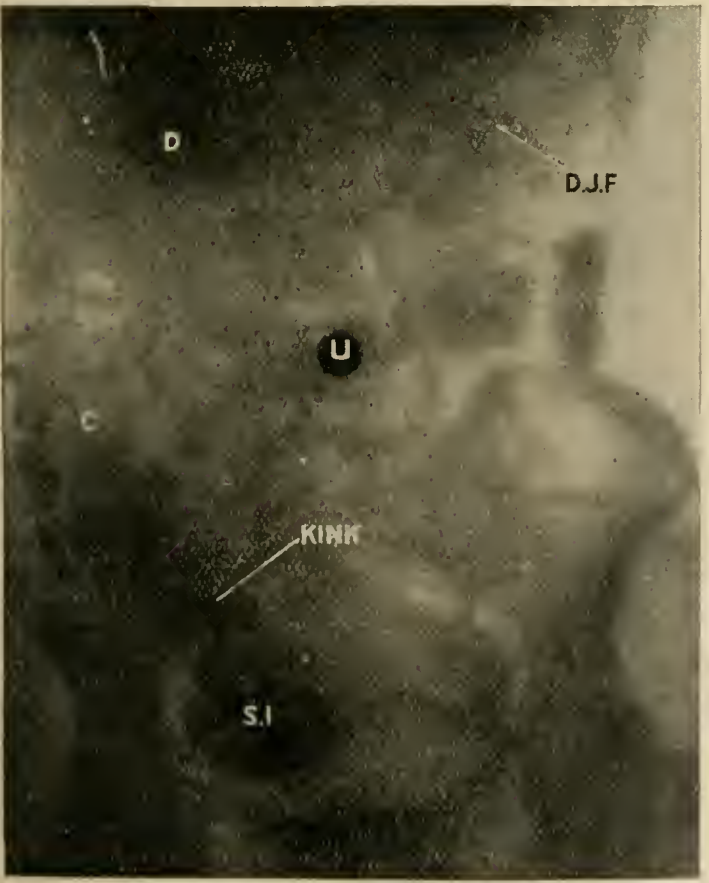

Fig. 6.—D.J.F. Duodeno-jejunal flexure. D. Duodenum. U. Umbilicus. C. Cæcum. S.I. Small intestine.

The Small Intestine.—When the bismuth food leaves the stomach it rapidly traverses the jejunum and accumulates in the lower loops of the ileum, which are coiled in the pelvis. The terminal part of the ileum ascends vertically to the cæcum. As it crosses the pelvic brim it is frequently found to be bound down to the latter by adhesions which cause kinkng when the patient is in the erect position. Acute or sub-acute inflammatory processes in the appendix are often responsible for the production of these adhesions. On raying the patient in four to six hours after the meal the terminal part of the ileum, as also the cæcum, can be studied. Kinks, if present, can be observed, but before making a diagnosis the ileum should be palpated in order to determine its mobility. I will show you several slides in which ileal kinks are to be seen, and I may add that the existence of these kinks was proved by operations. Fig 6.

The Large Intestine.—From its size and situation the large bowel readily lends itself to X-ray examination. It is at once recognised by being segmented.

The cæcum lies in front of the right iliac bone, but it is frequently dropped into the pelvis. In these latter cases it has a complete mesentery. It is often very large and flaccid. The appendix can be outlined also, but its shadow may be superimposed on that of the cæcum, which latter must be pressed upwards before it comes into view. The hepatic flexure extends upward to the margin of the right costal arch. The transverse colon crosses the abdomen at the level of the anterior iliac spines, and the splenic flexure is situate just beneath the left lower ribs. The descending colon drops vertically to the sigmoid and rectum. The transverse colon is often elongated and ptosed, and in its first part it may descend abruptly and be fixed to the ascending colon by adhesions or a Jackson's membrane. In these cases the appearance of the large bowel is like the letter H.

Ptosis of the large intestine is frequently met with, and I will show you photographs where it is seen to have dropped into the pelvis. Fig 7.

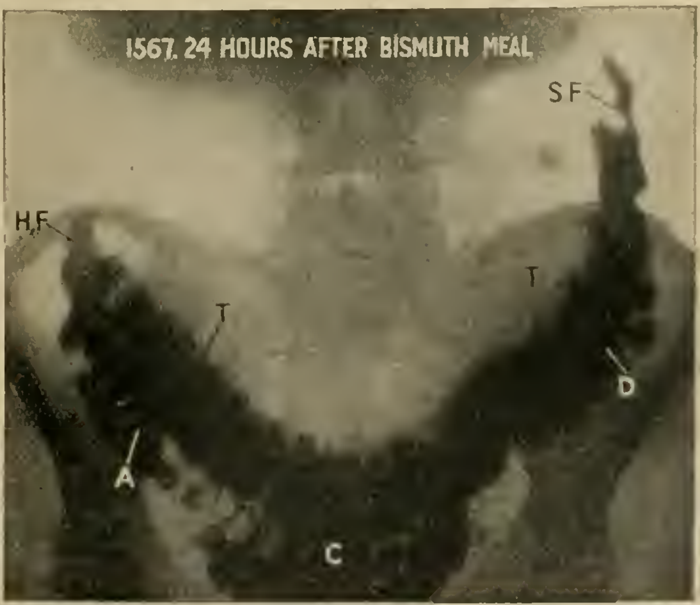

Fig. 7.—H.F. Hepatic flexure. S.F. Splenic flexure. C. Cæcum. A. Ascending colon. D. Descending colon. T.T. Transverse colon.

The normal time that the bismuth food takes to pass through the various parts of the intestinal tract may be stated to be as follows:—Food begins to pass through:

Pylorus, five to ten minutes after meal.
Stomach empty, four to six hours after meal.

Food enters cæcum, three and a half to four hours after meal.
Small intestine empty, seven hours after meal.
Ascending colon full, six hours after meal.
Splenic flexure reached, eight to nine hours after meal.
Rectum can be seen, from 20 to 24 hours after meal.

It must not be forgotten that the administration of purgatives on the days immediately preceding the giving of the bismuth meal increases the rate of flow of the intestinal contents for a day or two subsequently, and the routine administration of laxatives as a prelude to the X-ray examination of the intestinal tract is open to objection for this reason. While, however, the patient must not be suffering from diarrhœa at the time the examination is about to be made, care must be taken that constipation is not present.

HEREDITY AND SKULL FORM. (a)

By W. H. BROAD, M.D.,
Lecturer in Physical Anthropology, University of Liverpool.

As a preliminary to this lecture it is necessary to refer first of all to a few anthropological details.

Anthropology is the "science of man." *Physical anthropology* deals with man's physical characteristics, and especially those which differentiate him from the higher or anthropoid apes, as well as those characters which separate the human family into different races. On the present occasion we are concerned for a brief time with the shape of the cranium. Man's axial skeleton consists of a series of discs—the centra of the vertebræ—each with a posterior arc, the neural, and a larger anterior, or costal arc. These by their aggregation form a posterior canal, which contains the spinal cord, and an anterior, which contains the organs of respiration, digestion, and reproduction. The skull represents the modified upper end of the axial skeleton, and consists of three modified vertebræ, the centra of which are represented by the basi-occipital portion of the occipital bone and the bodies of the sphenoid and ethmoid. The posterior or neural canal becomes the cranium enclosing the brain, and the anterior or visceral arc forms the face, and contains the organs of sight, smell, and taste, and the apparatus of mastication. Although very many measurements are necessary to determine the anthropological characters of a skull, only two will be considered for the present purpose—namely, the cranial capacity and the cephalic index. The capacity of a cranium is determined by filling the cavity with some such medium as small shot, fine sand, or millet seed, which is then carefully measured. If the cranial bones are incomplete, and do not permit of gauging, recourse is had to the formula:

$$\frac{\text{height} \times \text{length} \times \text{breadth}}{2 \times 1.135}$$

which gives the *estimated* capacity.

The most striking characteristic which separates man from the anthropoid apes is the capacity of the cranium; the highest recorded capacity amongst anthropoids is 573 c.c., whilst in the lowest human type—the aboriginal Australian—the average is 1,100 c.c. Considerable difference exists between the cranial capacities of different races. If we take the average racial cranial capacities, we find the Australian aboriginal—as above mentioned—the lowest in the scale, an increased capacity in the yellow races, and the maximum amongst the civilised white races, the average for Great Britain being, for example, 1,550 c.c. Cranial capacity appears to vary with intellectual endowment, when taken as a racial character, but individually a capacious cranium does not *ipso facto* betoken mental ability.

Cephalic Index.—By means of callipers the maximum length is measured, and also the greatest breadth. From these measurements the *cephalic index* is determined thus:

$$\frac{\text{greatest breadth} \times 100}{\text{maximum length}}$$

Obviously it represents the percentage of breadth to length. In a long, narrow cranium the index will be at a lower figure than in a more rounded skull. When the cephalic index of a skull exceeds 80 it is termed *brachycephalic*, or broad-headed; when it is below 75 it is called *dolichocephalic*, or long-headed. Indices between 75 and 80 are *mesaticephalic*. Dolichocephaly is found as a racial characteristic of the black races; the Mongolians are brachycephalic, whilst the white civilised races usually possess mesaticephalic skulls. The extremes of dolichocephaly and brachycephaly are found respectively amongst the Eskimos (71) and the Lapps (86). It is curious that two races geographically close are so dissimilar physically, the explanation being that the former represent the earliest aboriginals of North-East Europe, a dolichocephalic race of the Glacial period, whilst the Lapps are the descendants of prehistoric Mongolian invaders.

Reference must be made in discussing racial head-form to the curious custom of artificial deformation of the skull, prevalent even at the present time in the Caucasus, the Crimea, Silesia, Tahiti, and Malacca. Skulls of the Incas or ancient Peruvians very frequently exhibit artificial flattening of the skull from before backwards. Religious motives, racial custom, or distinctions of caste were assigned as the reason for this custom. It was practised on both sexes, and of course during infancy. The operation was performed by applying pressure by means of boards, straps, or by manipulation. Goss maintains that where this custom is practised on both sexes, a few generations produce an inherited deformity. Cranial deformations due to other causes must also be taken into account when dealing with head-form—*e.g.*, pathological, posthumous, and synostotic (precocious union of one or more cranial bones).

Before leaving the subject of anthropological consideration of the skull-shape, I will refer to the curious correspondence which exists between the shape of the cranium and the hair in section. The black races are markedly "long-headed": the negro's hair in section is much longer than broad; the characteristic Mongolian skull is "round," as is also the section of his hair; and, finally, the head of the European corresponds in shape with the section of the hair in being a "medium" between the long and round shapes. The anthropoid ape, man's nearest ally, has since the Tertiary age made no progress whatever towards a higher state of intellectual development. Huxley has shown that the central nervous system of man and that of the anthropoid ape coincide structurally. There is also a correspondence in the viscera, bones, joints, and muscles. Especially with regard to the *size* of the brain, however, the difference is remarkable. The carcase of a full-grown gorilla is heavier than an average-sized European; but a healthy human brain would rarely be less than 32 ozs., whilst the largest ape's brain would not exceed 20 ozs. in weight. Duckworth gives the respective ratios between *brain weight* and *body weight*, in man and the gorilla respectively, as 1 : 36 in the former and 1 : 220 in the latter.

Most important is the *development* of the brain, and especially of the *fore-brain*. The cranium or

---

[a] A lecture delivered before the Liverpool Eugenics Education Society.

"brain case" assumes the size and shape of its contents; in other words, the brain shapes the cranium, and not the cranium the brain. The anterior lobes or frontal portion of the human brain are intimately associated with man's higher intellectual powers. In the left frontal lobe is the nerve centre which controls speech—the most important faculty of man. The fore-brain is poorly developed in apes, and the frontal portion of the cranium is ossified very early in life. Professor Deniker has shown that scarcely any growth occurs in the anterior portion of the ape's brain after the first year of life. The cranial sutures close early also in the anthropoids. In this respect (the early closure of the sutures) the skull of primitive man resembles that of the anthropoids. In the present time the cranial sutures do not begin to synostose until middle life. Broca affirms that the more the brain is exercised the longer the sutures persist. In idiots very early synostosis certainly does occur. According to Professor Ripley, the shape of the human head is one of the best available tests of race known. Its value is, at the same time, but imperfectly appreciated beyond the inner circle of professional anthropology. Yet it is so simple a phenomenon, both in principle and practical application, that it may readily be of use to the traveller and the not too superficial observer of men.

Of all racial characteristics, or, in other words, *hereditary* characteristics, the most important is skull-form. The reason that skull-form is primarily the chief expression of racial differences lies in its immunity from all disturbance from physical environment. Other racial characters, such as colour of hair and eyes, and stature especially, are open to modification by local circumstances; so that racial peculiarities are often obscured, or entirely reversed, by them. On the other hand, the general proportions of the head seem to be uninfluenced either by climate, by food supply or by economic status, or by habits of life; so that they stand as the clearest exponents which we possess of the permanent hereditary differences within the human species. It is generally accepted that rough stone flints found in late Tertiary and early Quaternary deposits are human artefacts, and prove the existence of man on the earth at these periods. Further, the upper portion of a cranium, a thigh bone, and three molar teeth were discovered in Java, on the banks of the Trinil River, in 1894, by Professor Dubois, in a Tertiary volcanic deposit. He gave the name of *Pithecanthropus erectus* to this animal, which has since been admitted to be human. The cranial capacity was estimated at 855 c.c., the sutures were synostosed, the brow ridges were prominent, and from the length of the femur (455 mm.) the stature was computed to be approximately 4 ft. 8 ins. In 1856 Fuhlrott discovered portions of a skeleton in the valley of the Neander, near Düsseldorf, together with early Quarternary or Glacial fauna. The cephalic index was 73.9. Massive brow ridges and synostosed sutures were exhibited, and the estimated capacity was 1,230 c.c. Marked narrowing of the frontal bone was evident—a condition reproduced to a certain degree in aboriginal Australians. The height of the individual was approximately the same as *Pithecanthropus*, but the whole skeleton is much more massive, and the thigh bones show strong muscular attachments, and are also curved in a manner that proves he must have walked with a bend at the knees. This individual (sometimes referred to as belonging to the Canstatt race) existed during the Pleistocene period of the Quaternary era. Then later were discovered the Spy, Cro-magnon, and other specimens of primitive man.

Following the Glacial period, a considerable change in climate occurs, and we have the advent of the Mediterranean race, or the Iberians, who peopled the whole of Western Europe. They were of short stature, with oval faces and markedly dolichocephalic skulls; the brow ridges were not abnormally prominent, and they had dark eyes and black hair.

The Iberians formed the primary stock from which the existing inhabitants of Great Britain and Western Europe are derived. These were the only inhabitants of the British Isles at the close of the palæolithic period. The earliest inhabitants of Britain were decidedly "long-headed"—more so than any Europeans to-day. The present Eskimos are regarded by some authorities as belonging to the same race, Boyd Dawkins agreeing with this theory. The next population in these islands was characterised by a considerably higher culture. Owing to their peculiar mode of interment, these were known as the "long-barrow" type, and still exhibit marked dolichocephaly. Succeeding was the "round-barrow" period. The culture of this period is greatly superior to the preceding era, as evidenced by the implements, pottery, etc. But more remarkable than the advance in culture was the extreme "broad-headedness," the cephalic index averaging 83, or 10 points more than the "long-barrow" average. The generally accepted view among anthropologists is that the "round-barrow" men came over from the mainland, bringing a culture derived from the East. Thurnam's view is that they were Celtic emigrants from Brittany; Dr. Rolleston inclines to the opinion that they were from Denmark.

After this we have the great Teutonic invasion from the north mainland, which ultimately settled the racial character of these islands. The Teutons (consisting of Angles, Saxons, Franks, Jutes, and Frisians) were, roughly speaking, all alike in physical shape—tall, tawny, blue-eyed, and with dolichocephalic skulls of large capacity. Their conquest was as much an ethnic conquest as one of force of arms, settling, as they did, in these islands, eventually interbreeding with the natives, and, as it were, imposing their racial characters on their descendants. Hence, briefly put, the people of Britain are first the Iberian stock, slightly modified later by the Mongolian invasion, but eventually absorbed into the Teutonic. Put in other words, the people of England are to a very large extent of Teutonic origin, into which stock elements of the mixed population of England have been grafted. The race thus formed has greater vigour and pliability of character than would have been the case had it been a pure race.

The prevailing type of skull-form in Britain to-day is that of the mesaticephalic type, the cephalic index averaging for the whole country 77 to 79. The long-headed type of skull, combined with a high cranial capacity, is characteristic of energy, domination in military and political affairs, assertive and enterprising—surely applicable to the English-speaking race, and the reason for the proud position of that race to-day. This racial character has been handed down to us by our ancestors as a heritage we ought to be proud of, and surely it behoves us to see to it that we shall hand it on to *our* successors unspoilt. Are we doing this? Karl Pearson says: "We are ceasing as a nation to breed intelligence as we did fifty to one hundred years ago. The mentally better stock in the nation is not reproducing itself as it did of old." Dr. Macnamara, in "The Character of the British People," states that "from an examination of individuals forming the labouring classes of London and other large towns, it is found that the third generation of town-dwellers shows a tendency to a reversion to the Iberian type at the expense of the Teuton element. Sociologists offer various remedies, such as segregation of the naturally defective, the lethal chamber, sterilisation of the unfit, emigration, and so on, but undoubtedly race culture or literal 'good breeding' is *the* remedy." Sir Francis Galton affirms that "eugenics must be introduced into the national conscience like a new religion. It has indeed strong claims to become an orthodox religious tenet of the future, for eugenics co-operates with the workings of nature by securing that humanity shall be represented by the fittest races. What nature does blindly, slowly, and ruthlessly, man may do providentially, quickly, and kindly. As it lies within his power, so it becomes his duty to succour neighbours who suffer misfortune. The improvement of our stock seems to me one of the highest objects we can reasonably attempt."

I have endeavoured briefly to show how our most important racial characteristic—skull-form—has been acquired and maintained by the influence of heredity; and if an interest has been awakened in the study of anthropology, the object of this short lecture is attained.

THE TREATMENT OF TUBERCULOUS JOINTS BY THE INTERNAL AND EXTERNAL USE OF IODINE.

By THOMAS DUTTON, M.D., M.R.C.P.

There has been so much discussion lately on the treatment of tuberculosis and tuberculous joints, some advocating tuberculin, while others support the knife, during which time I have been curing case after case by the above method of treatment with the addition of careful dieting, that I think the readers of the Medical Press and Circular may like to read the record of two recent cases which have undergone a most gratifying and quite satisfactory cure. What is more, the cases are still in the flesh and can be seen by any practitioner. I cannot, therefore, understand the new school of physicians and surgeons, the former using a most dangerous remedy, without any certain belief in its virtues as a cure, while the latter, when they strike a tuberculous joint, strike a danger zone, the consequences being most uncertain and fraught with the greatest danger to the patient. Although I own there are some brilliant successes. Since the close of that most fortunate time for the patient, I allude to the pupilage days, the young surgeon never has to compound drugs and see with his young eyes what matured practical skill can accomplish, knows now of no other treatment but by the knife, which, I believe, if only used in the interest of the patient, would thin their ranks and make many return to the far more difficult and scientific branch of treatment by drugs, diet, hygiene, included in the term medicine.

Case I.—M. E., circi, twenty-two years of age, was advised to consult me, after being under two learned practitioners, the last one gave a very grave prognosis and advised going to Guy's Hospital to consult a surgeon. She was a complete cripple, walking on crutches and had had a plaster splint on the leg for a year, besides being tortured by so-called open-air cure.

March 12th, 1912.—On examination I found the right knee-joint much swollen, very tender to the touch, most marked over the patella, the skin over the joint had a "par-boiled" appearance (a sure sign of tuberculosis), and there was evidence of fluid in the joint.

The subjective symptoms were: Great depression of spirits with a hopeless countenance, insomnia, loss of appetite, loss of flesh and anæmia. The pulse was small and weak, 94 per minute, temperature 99°.

I prescribed iodide of iron internally and a soluble iodine ointment to be applied night and morning, after the joint had been well fomented. A carefully constructed diet, with little waste material.

I advised the so-called "open-air" treatment to be abandoned, she was to avoid like poison, cold damp air, especially night air, and keep her window closed, but to take every advantage of warm, dry air and the sun's rays (according to my treatment for a quarter of a century of the cure of tuberculosis by the sun's rays). I also advised the splint to be abandoned.

March 18th.—She walked into my consulting room on her crutches, smiling and looking cheerful, and the reason, was, she had lost the dreadful aching pain and had been able to sleep and acknowledged it was quite a comfort to be free from cold air at night. "If you do nothing more for me I shall always be grateful for the relief you have given me." The symptoms were about the same, but the skin over the joint looked slightly rosy and there was less tenderness.

There was a gradual improvement week after week in the disease and more movement in the joint, and I instructed her how to go through some passive movement daily.

May 6th.—Patient's improvement so satisfactory that at her request I allowed her to go to Chertsey to see her mother. There a most unfortunate accident happened; trying to show how well she could bear her weight on the leg, the crutch slipped and she fell down some stone steps. She at once returned to London and came to see me. I found the ankle-joint much swollen and painful, but the knee-joint, although painful, was not much swollen. I was able to assure her that I believe, although the cure would be delayed, it would go on slowly, and my prognosis with the treatment being carried out actively, was correct.

July. 15th.—Patient came under my personal daily care. I made her discard her crutches and walk round the table every few hours with the aid of a thick walking stick. I directed the passing movements of the joint and put her on iron and strychnine mixture.

August 27th.—Patient could walk quite well and I discharged her as cured, but advised her to bathe the knee and ankle with hot sea water for a month, night and morning.

January 2nd, 1913.—Miss M. E. visited me to show me how well she could use the leg. She stated the only movement that was not so good as the other knee-joint was when going upstairs. The leg is quite normal.

Case II.—July 17th, 1912.—E. C., 15, came to me with her father, who told me his daughter had been treated at Guy's Hospital for four years, with tuberculosis wrist-joint. She had had hundreds of injections of tuberculin, but was gradually getting worse.

The right hand was in a splint, quite useless, the joint was swollen, the skin looked par-boiled, and there was a dull, aching pain. I was told she had been under so-called open-air treatment and had caught cold after cold. Pulse weak, 80, temperature 100° at night. I put her on the same treatment as the previous patient, instructed her to at once abandon keeping her window open at night and to avoid cold damp air, in every form, night and day. I pushed the iodide treatment until a pustular rash came out over her face and forehead

July 26th.—There was a great improvement in the look of the hand, the skin had a rose colour. She had lost all the dull, aching pain and slept well. The special diet prescribed had agreed well with her, having increased 2 lbs. in weight. I ordered the splint to be removed and the hand only supported in a sling. I also prescribed heliotherapy.

August 15th.—Still gaining in weight. Can move all fingers when hand is placed on a book.

October 2nd. — Improvement has gone on steadily. She can now use her hand fairly well. I advised the ointment to be discontinued and hand put into hot sea water for ten minutes every day. Increase in weight, 12 lbs.

December 10th.—The father writes:—"It really seems too good to be true after so long a time, but she uses her hand as if nothing had been amiss with it, and never feels anything at all of the old trouble."

In conclusion. I may state again I have many other such cases in different parts of England. Two cases of tuberculous glands treated with the injections of pneumosan, before the iodide treatment, did so well that a surgeon wrote and said he would always hesitate before operating on such glands in future.

ON THE LEPROSY BACILLUS AND ALLIED BACILLI. (*a*)

By Major E. R. ROST, M.R.C.S., L.R.C.P.Lond.,

Indian Medical Service.

Since 1904, when I published the results of my early work on leprosy in the *Indian Medical Gazette*, the number of workers has increased, so that we find in the March number of the *Transactions of the Society of Tropical Medicine* no less than six papers on the subject. Dr. A. G. R. Foulerton's paper in the *British Medical Journal* of February 10th, 1912, corroborates the view which has been expounded by the work of Capt. B. Williams and myself, and which was arrived at independently and worked out in collaboration later in India.

There is now no doubt whatever that the cultivations I obtained prior to 1904 were true cultures of the leprosy streptothrix. The leprolin which I made from these cultures produced such remarkably beneficial effects, that notwithstanding the severe adverse criticism which my work obtained, I was justified in my belief that I was right. In addition I had the clinical reports of medical men in different parts of the world, who had used the leprolin in all cases with success in varying degrees. Although the Government of India stopped the use of leprolin on the ground that it was prepared from contaminated cultures, the work was proceeded with, and I eventually, in 1909, discovered a method of obtaining cultures of the leprosy streptothrix on solid media, and worked out its pleomorphism, particularly as regards acid-fastness. The vaccine produced from these cultures produced the same beneficial effects with the same reaction as was produced by the original leprolin, and moreover, the varying acid-fastness and pleomorphism, together with the streptothrix nature of the growths, explained the error which my adverse critics had fallen into, with the loss to suffering mankind which the stopping of my treatment caused.

It will not be necessary for me to repeat in this paper the details connected with this work and the characters of the cultivations; these have already appeared in the *Scientific Memoirs of the Government of India*, and elsewhere. Briefly stated the bacteriological points are as follows. A medium is prepared of lemco broth (without salt or peptone) 250 c.c., milk 50 c.c., and the distillate prepared by condensing the steam passed over fish to which has been added a little caustic soda 250 c.c. This medium is inoculated with the blister fluid of lepers, preferably spontaneous blisters, or the juice expressed from nodules which do not bleed. Tubes of this medium are inoculated at room temperature, and after three or four weeks a surface growth may be obtained. Subculture on nutrient agar plates will show discrete colonies after about a week, of the size of a pin's head, opaque, orange-red, red, or grey, raised in the centre, humped, and moist. These colonies are circular, opaque with regular unbroken margins. Subculture on broth produces a surface growth of rosette-shaped masses, the broth remaining clear. The special differential characteristics are as follows:—

I. Examined at different periods of its growth a culture will show (*a*) a non-acid-fast streptothrix in the mycelial stage producing acid-fast rods. (*b*) A non-acid-fast diphtheroid bacillus producing acid-fast rods. (*c*) An acid-fast bacillus in clumps or an acid-fast mycelium.

II. The organism grows on starch and potato-glycerin, but not on pure albumen.

III. Its acid-fastness varies according to the fatty nature of the medium used.

IV. It stains readily with the cold simple aqueous aniline dyes, and is gram-positive.

V. It is non-motile.

VI. It grows best at 30° C., and after a few generations from original culture, is found to have grown after two or three days.

VII. It is very pleomorphic.

Several strains have been cultivated which differed slightly in appearance, and after prolonged subculture became more alike.

VIII. On a glucose litmus medium there is no formation of acid or gas; on mannite litmus medium there is no formation of acid or gas; on dulcite litmus medium there is no formation of acid or gas; on lactose litmus medium there is no formation of acid or gas; on bile salt media there is no growth.

IX. After exposure to 80° C. for fifteen minutes no subculture was obtained.

X. 1 in 500 bile salt prevents growth. Sheep's bile 1 in 100 prevents growth.

XI. Indol reaction is negative.

A reference to Dr. Foulerton's Milroy lectures will show that this organism belongs to the streptothriceæ, and the work of Capt. T. S. B. Williams, I.M.S., has quite clearly elucidated this in our collaborated work. I have obtained six strains of streptothrix from lepers, and these have been compared with the strain obtained by Capt. Williams. These strains at first showed slight variations as to acid-fastness and colour, but by long continual subculture they have become more alike. These seven strains have been injected into mudfish and frogs, and an identical disease has been produced in the fish and frogs by one injection of these cultures. The injections were made intra-peritoneally, and after from one to three months the fish or frogs died, the peritoneum, omentum, and surface of the liver being found to be studded with small white vesicles, containing acid-fast bacteria. In some cases the granulations were so well marked that the peritoneum appeared full of vesicular balls, while in others they were difficult to find. The cultivations obtained from these vesicles were injected into mudfish, and these fish died from the same disease. The cultivation for a long time defied me, but after defeating the numerous organisms with which these fish abound by flinging them into boiling oil, I succeeded in obtaining growths on fish-milk-broth in the cold incubator. Over 200 mudfish obtained from various sources in Lower Burma showed no such disease. It thus appears that leprosy streptothricosis may be induced with apparent ease in cold-blooded animals, and the recent work of Dr. Maurice Couret (*Journal of Experimental Medicine*, vol. xiii., No. 4, 1911), and of Dr. C. W. Duval (same journal, vol. xiv., No. 2, 1911) corroborate these experiments, though apparently they did not produce a fatal disease, as their injections were made subcutaneously.

It has also been shown by me (*Scientific Memoirs*, No. 42) that the disease can with difficulty be produced in the monkey by repeated injections of the

---

(*a*) Paper presented to the International Medical Congress, Section of Bacteriology and Immunity, London, August, 1913.

streptothrix, so that it would appear that the disease is more readily induced in cold-blooded animals than in warm, and this fact rather opens one's eyes to the possibility of the disease existing naturally in cold-blooded animals. In this connection the work which has been carried out on the so-called fish-tubercle disease by Hoorman, Morgenroth, Nicolas, Leseur, Bataillon, Dubard, and Terre (*Handbuch der Fischkrankheiten,* Bruno Hofer) is interesting, but I find no records of any streptothrix disease existing naturally in fish. This is surely a line of research worthy of investigation. However, my practical experience has proved to me that leprosy is inoculable through the skin. I have on record two cases where a slight nodule appeared over the site of a previous wound, in both cases the patients had lived and worked in a leper asylum; in both cases the nodule was excised and showed acid-fast bacilli in groups; in both cases there was no recurrence, no metastasis, no reappearance of the disease. Yet I am of opinion that if these two cases had been further exposed to inoculation repeatedly, the disease would have developed. My experiments on the monkey showed that we reduced his resistance so much that the disease did eventually take. Leprosy is, as a rule, such an insidious disease that any accurate history of infection is impossible. It is my belief that the disease is in the great majority of cases contracted through infected clothing. I examined the vests worn by lepers and obtained from one a cultivation of the streptothrix some years ago. Where skin diseases abound points of inoculation will therefore be very multiple and resistance easily broken down by persistent absorption.

Clinical Report.

The original cases treated by the old leprolin (which was a filtered preparation of very dilute cultures of the streptothrix) were reported in the *Indian Medical Gazette* for May, June, September, December 1904, and by Doctors M. de Beurmann and M. Gorgenat in the *Extrait des Bulletins et Mémoires de la Société Médicale des Hôpitaux de Paris,* December, 1907. Also in *Medicine* (Detroit), vol. xi., No. 3, March, 1905. Three of these cases have been seen by me lately, and there is no sign of the original disease, while I have received reports of four other cases treated and cured by the original leprolin who are stated to be in perfect health. At present I have thirty cases under treatment by the vaccine method, and since adopting this treatment in March, 1909, four cases have been discharged cured and one is being kept under observation. Of the twenty-two cases published in the *Indian Medical Gazette* for July, 1911, and July, 1912, several have improved to such an extent that only slight signs of the original disease remain, while in only two cases has there been no change either for better or for worse in their condition. It will be unnecessary for me to go into the detail of each case, I show here the results of treatment of some cases by photographs taken at different periods, but I will detail the special points which have been found to influence this treatment.

First, the vaccine is made from six weeks' broth-cultures of mixed streptothrix, *i.e.,* from the seven strains of streptothrix obtained from the seven original cultures of leprosy streptothrix. The culture is agitated and filtered through blotting-paper to remove large masses of bacteria, and is then sterilised. The method of weighing out dried culture and making up a percentage solution was found to be unnecessary, quite as good clinical results are obtained by the present method, and the reactions do not appear to vary.

Secondly, the vaccine is injected intra-muscularly once a week; for anæsthetic cases doses of from 1.5 to 3 c.c. can be given, while for tubercular or nodular cases not more than 1 c.c. should be given. The reaction varies considerably according to the dose and according to the severity of the case treated. The reaction temperature in a bad tubercular case may reach 103° F. with a dose of 1 c.c., or in a slighter nodular case may be only 100° F. The temperature generally lasts only three or four hours, during which time the nodular areas become red and hot. In anæsthetic cases the reaction is as a rule quite slight or nil, but there is generally a noticeable flushing of the lighter patches. The patients have all stated that the pains in the bones and joints are relieved, and that the sensation of heaviness of the limbs becomes lost.

The vaccine treatment has a very marked effect on ulcerations, and I have seen ulcers, which have defied treatment for many months, heal up in a few days after one injection. On the other hand, it occasionally happens that the reaction is very severe in bad nodular cases, even with small doses, and suppuration of nodules is liable to occur, but subsequent injections of vaccine have in these cases caused healing of ulcerations, and we may therefore look upon such severe reactions in bad cases as beneficial. In no case has the disease been accentuated, and in no case has there been any untoward result. Cases of leprotic fever have been markedly benefited by injections of the vaccine, and leprotic fever is no contra-indication to its use, but quite the reverse, as in these cases there is an unusually rapid subsidence of nodulation, as the temperature gradually reaches normal. The thirty cases which have been treated at the Kemendine Leper Asylum have had no other treatment beyond the weekly injections of vaccine. But there are certain other valuable adjuvants which may be beneficially employed, and which I have found to be useful previous to the present vaccine treatment, and which have been employed with great success in some private cases. Fish and milk should be excluded from the diet and fairly large doses of sodium chloride taken daily. Salt water baths and the application of erythema-causing ointments to the nodular patches, just after the injections of vaccine, in order to cause a better blood supply are advantageous. An ointment composed of sodium chloride and vaseline should also be rubbed into the affected areas.

With regard to any criticism of the results I have obtained by the vaccine treatment, I am fully aware of the fact that the disease does in some cases wear itself out or may spontaneously cease to progress at any period of it course. I have, moreover, carried out experiments with vaccines of other kinds of streptothrix, such as the smegma bacillus and the timothy grass bacillus, and I find that these vaccines will produce in larger doses a similar reaction, but no appreciable improvement or otherwise was noticed by their use. These facts are interesting as showing the relation between the various streptothriceæ, and that there is some substance contained in them which appears to cause a similar reaction. Similarly cases of actinomycosis have been treated by vaccines prepared from the particular strain of the "ray fungus" found in the discharge with a certain amount of improvement. Knowing that the leprosy streptothrix is an exceedingly pleomorphic organism, which fact, to my mind, explains the great variety of clinical manifestations, it would appear desirable to cultivate the streptothrix as far as possible from each individual case. We have produced five strains, and reports show that several more have been obtained, so that before long either by my method or the amœba method, cultivation from cases of leprosy should become common. I have, moreover, found that since using the mixed vaccine prepared from all seven strains in my possession, that the improvement of the cases treated has been more pronounced and uniform. The first case (of which I show photographs taken at various stages during the treatment) was an exceedingly advanced nodular and anæsthetic case with furfuraceous thickenings all over the body, so that there was not a square inch of healthy skin. Treatment was commenced on March 22nd, 1909, with T. L. O. vaccine 1/1000 grain, and was altered to the mixed vaccine after July, 1910. His temperature reactions reached at first 103° F. on the day of injection, and were slighter on the day following, as the temperature chart shows. By July, 1910, his body was completely clear of nodules and slight discolouration only remained. At present he has very slight thickenings on the fingers and lobules of the ears, otherwise he has no signs of the original disease.

The second case (illustrated by photographs) is that of a young Burmese girl, aged 10, who had thickenings on both cheeks, ears, nose, with ulceration and discharge from the nose, thickenings of wrists and fingers with anæsthesia; ulceration of feet and anæsthesia both legs; nodulation on back, gluteal region, and thighs. These signs have now practically disappeared except for slight thickening still remaining on the cheeks.

The third case is that of an Englishman who had been treated with success by the old leprolin in India. After the treatment was stopped the disease became rapidly worse, extending all over the body. He was an advanced case, with raised nodular areas all over the body, iritis, ulceration of alæ nasi, pendulous ears, and loss of sensation in the extremities. At one time the reaction was so severe that a large number of the nodular areas suppurated, but they subsequently healed up very quickly, leaving depressed scars. He left the asylum "cured" in April, 1912, having had no signs of the disease since December, 1910.

The fourth and fifth were nodular cases in Burmese young women, but they did not continue the treatment regularly and had few injections; they have, however both improved very much.

The sixth case was that of a Eurasian lad, æt. 9, with an anæsthetic patch on the right thigh, one anæsthetic patch on the chest, patches on the left elbow, wrist, and contractions of fingers. Treatment was started in October, 1909, and weekly injections were continued till August, 1910, when he was discharged "cured." He is still free from any signs of the disease.

The seventh case is that of a Roman Catholic priest, a severe nodular case as the photographs show. In this case also suppurations occurred after injections of the vaccine, the ulcerations subsequently healing. He left the asylum in July, 1910, and has continued the injections since. His face is now entirely clear of nodules, and there remain only a few nodules on the fingers and body.

The eighth case was a mild anæsthetic case, a Eurasian lad with anæsthetic patches on the left and right cheeks. He was cured in two months.

The ninth case was that of a young Burmese girl, with anæsthetic patches on the face, body, arms, and legs. She has now greatly improved, the sensation having returned in all the patches, and the white skin having resumed its natural pigment.

The tenth case, a Tamil boy, æt. 10, an anæsthetic case, the face, arms, body, back, thighs, and legs having before treatment numerous patches. He is now practically cured; the colour of the skin of the patches has not yet assumed the normal colour.

The eleventh case, an Indian Christian, æt. 30, was also an anæsthetic case. The disease affected principally the left shoulder, right leg, and foot, with severe shooting pains. This man appears to be cured.

The twelfth case, a Eurasian lad, æt. 13, with a tubercular nodule on the chin, anæsthetic patches on the legs and thighs. He started treatment in August, 1910, and was reported cured in my first clinical report in July, 1911 (*Indian Medical Gazette*).

These cases were treated previous to July, 1911, and roughly analysed they show the following results:—

1st case.—Severe nodular and anæsthetic. Almost cured.
2nd case.—Nodular and anæsthetic. Greatly improved.
3rd case.—Nodular and anæsthetic. Cured.
4th case.—Nodular. Improved.
5th case.—Nodular. Improved.
6th case.—Anæsthetic. Cured.
7th case.—Nodular and anæsthetic. Greatly improved.
8th case.—Mild anæsthesia. Cured.
9th case.—Anæsthetic. Almost cured.
10th case.—Anæsthetic. Almost cured.
11th case.—Anæsthetic. Apparently cured.
12th case.—Nodular and anæsthetic. Cured.

Four are definitely cured, 1 is apparently cured, 3 are almost cured, 2 are greatly improved, and 2 have improved.

Of the next series of cases 10 were reported in the *Indian Medical Gazette* for July, 1912, and 8 are recent cases.

13th case.—Anæsthetic and nodular. Greatly improved.
14th case.—Anæsthetic. Greatly improved.
15th case.—Anæsthetic and nodular. Improvement.
16th case.—Nodular. Greatly improved.
17th case.—Severe nodular. No improvement.
18th case.—Severe nodular and anæsthetic. Improvement.
19th case.—Anæsthetic. No improvement.
20th case.—Severe nodular and anæsthetic. Marked improvement.
21st case.—Nodular and anæsthetic. Greatly improved.
22nd case.—Anæsthetic. Greatly improved.

The treatment must necessarily be slow in such a chronic disease, but to my mind sufficient progress has been made to warrant a further and more extensive trial, and to show that leprosy has now been brought within the scope of the rational treatment of disease, and the word "Incurable" may be erased from our text-books.

Finally, I would like to bring forward one point in the prevention of the disease which I have already touched on—namely, the importance, firstly, of segregation, and, secondly, the importance of sterilising all clothing which has been worn by lepers. I have frequently found lepers among the staff of servants of Europeans living in the East. Would anyone like to use the same washerman (dhoby), who is washing the clothes of a leper? And yet precautions to ascertain for whom one's washerman washes are exceedingly rare in the East. How easy it must be to saturate a vest, washed in the same tub with the vest of a leper, with leprosy streptothrix. How easy it must be for the contagion in that vest to become inoculated in a hot climate where almost everyone has lichen tropicus or some numerous points of entrance for infection, and those who have weak resistance to this disease are liable to contract it. It would be best then to allow this idea to be publicly known, particularly in the East where leprosy is so common.

OPERATING THEATRES.

HAMPSTEAD HOSPITAL.

Operations by Mr. Jackson Clarke.

(*Continued from page* 327.)

The following are further cases operated on by Mr. Jackson Clarke:—

Case 11.—Prolapsus Uteri—Rectocele—Cystocele.—S.T., æt. 38. Admitted April 20th, 1911; discharged July 24th, 1911. Admitted for pneumonia and asthma under Dr. Sutherland. Transferred to surgical side on May 22nd. *Operation.*—May 24th; C.E.—ether. Ventrofixation: shortening of both round ligaments. Anæsthetic was followed by another brief but well-marked attack of pneumonia. Vagina easily admitted five fingers. Rectocele. *Second operation.*—June 28th; $CHCl_3$. Perineorrhaphy. Vaginal outlet narrowed by excising portion from both lateral and the posterior walls. On discharge a cystocele appeared to be developing. The abbreviated walls held well, but there appeared to be very little support anteriorly. Patient desired to go home before any further operative treatment was done. The patient presented herself at the hospital a year after operation. Materially benefited: the os uteri no longer descended beyond the upper part of the vagina.

Case 12.—Pyonephrosis.—E.R., æt. 30. Admitted April 24th, 1911; discharged July 20th, 1911. Operated upon at the London Hospital in February, 1910, for a left-sided B. coli perinephric abscess. In a note the Surgical Registrar stated that part of the abscess was definitely within the kidney, and that a good deal of semicalcareous material was found in addition. No T.B. in urine. Kidney drained. Since the operation a sinus with purulent discharge has persisted up to admission to the Hampstead Hospital. May 2nd:

Cystoscopy by Mr. Thomson Walker. A worm-like process of thick, yellow pus, unmixed with urine, seen escaping from the left ureter. Ureteric orifices, trigone, and mucous membrane of bladder normal. May 10th: *Operation.*—C.E.—ether. Nephrectomy by Mr. Jackson Clarke. A thick layer of very hard scar tissue surrounded kidney. Kidney with its abscess cavity adherent to 12th rib and diaphragm. Organ removed piecemeal from its capsule. Vessels and ureter clamped and ligatured. One large tube. The same evening it was noticed that air was being sucked in through the drainage tube. The large extent of the cavity and its extending under the diaphragm explained this phenomenon. For three weeks after the operation a markedly remittent temperature was shown (maximum 103.6° on the second day), the sloughy walls of the sinus becoming gradually clear in this time.

Comments by Mr. Jackson Clarke.

The cases reported last week were operated on during a period at which circumstances placed the gynæcological as well as the general surgical beds in my charge. The gynæcological beds have since been taken over by my colleague, Mr. Glendining. One case of painful constipation was given as a contrast to show that not every case of abdominal pain and tenderness requires operation. Of the two cases given to-day one was the most pronounced condition of relaxed vaginal outlet that has come to my notice, and my interest in it, beyond doing the best for the patient, was to compare the result with such as one might expect from a bad inguinal or umbilical hernia. In my hands at least the radical operations for surgical hernias give more reliable results than bad cases of uterine prolapse.

One feature of the second of the two cases reported above, that of pyonephrosis, was the aspiration of air into the wound. This might have led to a suspicion that the pleura had been penetrated, but this was not the case

With regard to the remaining cases published last week, they explain themslves sufficiently, and I have to thank Mr. V. C. Vesselovsky, late House Surgeon, for collecting these and other cases for me from the hospital notes.

As regards the *technique* of the operations I will dwell on one point only—the use of special swabs with tapes attached, as shown in the accompanying block. The swabs are carefully stitched so that the edges do not fray out. Such swabs were incorporated in sets of sterile dressings prepared according to my directions by Mr. Martindale first some ten years ago, as shown in Fig. 1. This is a complete set of overalls, towels, swabs, gauze rolls and bandages, suitable for abdominal and other surgical operations. The swabs have attached to them tapes, which are left hanging outside any cavity into which the swab is passed; pressure forceps are applied to the free end of the tape to prevent the possibility of the swab being left in the cavity.

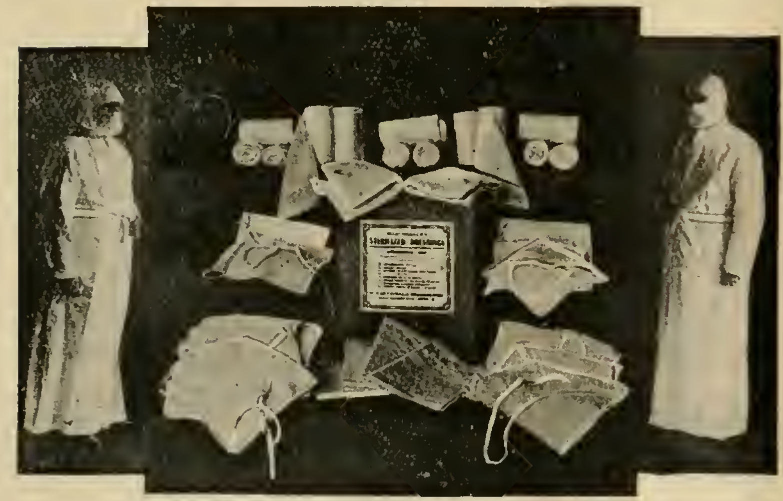

Fig. 1.—The Set of Surgical Dressings, etc.

The chief feature is that the contents of the tin being absolutely dry and hermetically sealed, they can be kept for any length of time, so that the surgeon can always have one or more sets at hand for use in an emergency. I have used these dressings for ten years for operations of all kinds, and I have not had any reason to suspect their being absolutely sterile—as, indeed, is to be expected from the mode of their preparation. The swabs in use at the Hampstead Hospital for abdominal operations are similar to those shown in the above illustration.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

AUSTRIA.

Vienna, Sept. 20th, 1913.

The subject of

Hydatid Moles

has been made the subject of very exhaustive discussion in the medical journals of Vienna, by Dr. Th. Kropiwriscki, of the Universitäts-Frauenklinik, Breslau. He prefaces his account of a long and interesting series of cases which came under his own observation with a sketch of the literary history of the subject, and gives afterwards a full *précis* of the existing knowledge of what long proved one of the mysterious problems of gynæcological pathology.

The term *mola* has descended to us from the Father of Medicine himself, through the intermediate linkage of Aristotle and Galen. But definite ideas on the subject of the present thesis are of quite modern growth, indeed. It took more than 2,000 years, from the date of the vague reference of Hippocrates, and the more definite indications of his junior contemporary, Diocles of Carystos, to arrive at the scientific pathological views of Virchow—which were curiously foreshadowed by the latter Greek observer. Erotianus, who wrote a commentary on Hippocrates in the time of Nero, had made suggestions regarding the genetic presence of degenerate chorionic villi which were misinterpreted by subsequent medical writers, and thus allowed to pass into oblivion. The Arabs, as representatives of the apostolic succession in medicine, extended the application of the term *mola* to all uterine tumours, inclusive of those of the walls of the matrix. In the recognised works on medical history too much credit is given to Schenk of Gräpenberg, for the original description of the hydatid mole. He appears, indeed, to have been the first to employ the term *mola aquea;* but in his description he evidently confuses this with other uterine tumours. The oldest genuine description of the hydatid mole that has descended to us is certainly that of Ætius of Amida, who occupied a distinguished position at the Court of Justinian in the early part of the fifth century. He also gave a fairly accurate account of the symptoms, and pointed out the frequency of the coincident presence of œdema. The fact of occasional coincidence with the condition of hydrops uteri leads us to suspect that Ætius sometimes confused this and other conditions of profuse watery discharge with the genuine mole.

Christopherus a Vega and Valleriola recorded their respective observations; and, a few years later, Ludovicus Mercatus, Physician-in-Chief to Philip II. of Spain, gave a brief account of the mole in his great work, "De Morbis Mulierum Communibus." In 1618, Carolus Piso referred the origin of the mole to "semen infecundum et crudum." Nicolas Tulpius followed with a description of two cases in his "Observationes Medicæ," under the heading of "Hydrops Uteri"—with the added comment that some called such "mola aquosa." Vallisnerius published an illustrated description in 1690, and formulated (in a letter to Malpighi) the view that hydatid moles originated from the placenta. Malpighi discussed the subject further in his own works, and indicated that the mass of the hydatids in molar pregnancy was referrable to the position of the chorion. Nearly at the same time, Ruysch published illustrated accounts of such cases, in which usually the whole—and in one instance a portion—of the originally normal placenta had been changed into masses of watery vesicles. After this date, a continued series of descriptions may be found, some of clearly recognisable hydatid moles, and others of cases of more or less obscurely similar nature.

The use of the microscope came at last to shed a new light on the dark ways of the hydatid mole. With the knowledge of the normal histological structure of the chorion and its villi came the ability to trace their pathological changes, and we can now readily recognise the insuperable difficulties which faced the older authors. But even in quite modern times the question was discussed: Was the mole a product of conception or not? For examples in Gluge's "Atlas of Pathological Anatomy" we find the venerable views of the helminthologists reproduced: that the hydatid moles were genuine entozoa, or actual bladder worms. Two prominent French authorities adhered to this view—Pereyard and Cloquet—who thought that they had observed spontaneous movements of the individual vesicles and noted their occurrence in a virgin. Bremser, in his discussion of Hydrometra hydatica, came to the conclusion that the hydatids were really structures which had each existence of its own, although his conceptions thereof seem hardly definite. Velpeau recognised that in the degenerate villi there were often no vessels; many were solid at first, and underwent branching growth which afterwards shrivelled, but in the case of hydatid mole persisted and underwent further development. H. Müller referred their source to the epithelial layer which underwent thickening, and became hollow only after the inner surface had become lined with a fibrous membrane—the so-called endochorion. Gierse and Meckel located their origin in the central cellular tissue of the villi, which, instead of continuing in the normal solid state, formed central spaces of various sizes, filled with serum, and crossed by a delicate network of fibres. This view was re-examined and completed by Virchow, and was thenceforward adopted by most authors. Marchand, however, advocated the conception that the genesis lay in a dropsical swelling of the connective tissue of the villi; and the deservedly prevailing view at present is that, in the formation of the hydatid mole, a more or less considerable proliferation of the cell-layers and the synzytium takes place, and that the products—especially in the latter—undergo degenerative changes, whereby the stroma in the central portions undergoes dropsical changes on account of incomplete nutrition. Hecker adopted the view of a primary defect of the allantois being the cause of the proliferation of the chorionic villi, but failed to explain thereby the presence of the villi and the vessels which are often present. Other writers would refer the ætiology to the relationship between mother and fœtus, and suggest syphilis as a cause; which was, however, demonstrable in but few of their cases. Keifer would associate hydatid moles with the use of diaphoretic agents, especially sodium salicylate, from his own observations of five cases. Such general diseases as chlorosis, anæmia, and nephritis appear to predispose, also disorders of menstruation. Most recent is Gottschalk's contribution to the ætiology, advanced on the basis of two cases observed by himself, that the growth of a typical hydatid mole, with vesicles of dimensions up to that of a hazel nut, may take place without having progressive epithelial proliferation, and that this process can have no genetic significance in the association. From all those hypotheses which have a scientific basis in observed facts we may come to the conclusion that the hydatid mole has already been formed and ready-made before any increased activity of the chorionic epithelium intervenes; the latter first comes in with the failure of the fœtal circulation in the molar mass, and only after destruction of the capsularis, which results from pressure-erosion, from the copious bathing of the already degenerate villi with maternal blood within the decidua, does the epithelium of the villi display the effects of excessive nutrition.

"How to Take Care of Baby" is the title of a little pamphlet by Dr. Selina F. Fox, which is published at 1d. by the Women's Industrial Council, 7 John Street, W.C. It gives some useful advice as to the management of infants in a cheap and handy form, and will no doubt find a ready sale.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

The Spread of Anthrax.

Dr. Watt, County Medical Officer of Health, Aberdeen, submitted a report to the County Council, under the Contagious Diseases of Animals Act, dealing with the case of an employee who a short time ago had contracted anthrax. Dr. Watt said that the man had a pimple on his forehead, and whilst following his occupation in working amongst some bags of bone meal his cap fell over his face, and in attempting to replace the cap he scratched the pimple, which commenced to bleed. In the course of a few days his face became swollen, and he went to a medical man, who recognised the disease and sent the man to the Infirmary, where he was operated upon and made a complete recovery. The bones which the man was working amongst probably came from Bombay, but he also stated that he was working amongst other bags, the contents of which might have come from any quarter of the globe.

The Chairman remarked that this case showed the danger of foreign bone manures, and he moved that the case should be reported to the Board of Agriculture, along with a statement pointing out that it supported the contention of the Committee that these bones should be sterilised.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents]

FRENCH DRAINS AND MALODOROUS FRANCE.

To the Editor of The Medical Press and Circular.

Sir,—I am not a doctor. I rarely see a medical paper. I am indebted to my friend "Anglo-Français" for the copy of your valuable journal of September 10th, which contains his letter under the above heading. I have lived long enough in France to have become more than sufficiently alive to the monetary loss the country sustains annually owing to the lack of public hygiene. Although not totally dissociated from trade, I am not a member of any British Chamber of Commerce over here. If I were, I would certainly feel inclined, as my friend suggests, to bring the question forward. This would give it the best chance of gaining further attention. The subject is avoided by French, and rarely referred to in English newspapers. Living a few miles outside the fortifications in an open, park-like space on the verge of the Forest of Vincennes, I have been able to keep a house with a garden where I can so far ensure my own sanitary safety. This is impossible within the city of Paris. The sanitary defects of the houses, with rare exceptions, are those described in your pages, whilst the water offers an especial danger. Every now and again it becomes of more than doubtful purity. It used to be common for the authorities to issue a periodical warning and advise the boiling of all drinking water. This is difficult in domestic life. It does not do away with the risk of typhoid infection through milk and other food materials that may have been treated with polluted water. Typhoid fever is, I believe, in Paris and other towns more apt to attack healthy young English people than natives. The latter seem immune from long contact with infection. I have a record of too many cases of typhoid among my British friends and acquaintances living in Paris and in Provincial French towns, whilst the cases of frequent sore throats and chronic lowered health have been very numerous. People who have so suffered go away and spread the facts. Those compelled to sojourn in France do all they can to dissuade others from getting into a similar position. I have just returned from a motor tour with friends—an Englishman and wife and their eighteen-year-old daughter. We have visited extremely attractive and picturesque towns, and have sometimes stayed at purely French hotels seldom visited by foreigners. It must be said that in the matter of water closets at least a considerable improvement has been brought about through the influence of the Automobile Club in hotels frequented by its wealthy members. In other hotels, in this and other sanitary directions the conditions remain, as a rule, truly shocking. For example, the last hotel we stayed at was a most picturesque building in a cathedral town not far from the main Paris-Calais route. It was an old posting house, probably of much older foundation. The central court from which the chaises used to start was glazed over and imperfectly ventilated. Out of this led the staircase to the bedrooms. This was very ancient, with small closed windows. In the corners, shut off by wooden partitions, on the landing and at the ends of the corridor, were the closets. The light and ventilation both came in over the partitions; there were no windows; that is to say, the closets in fact ventilated into the bedrooms, the doors of which formed the chief line of escape for the foul gases. The whole hotel was pervaded by a sickly odour. It made one's gorge rise, and effectually destroyed all relish for the super-excellent food cooked under the supervision of the landlord, himself a chef. I knew it was of no use, but my friend before our hastened departure on the second day spoke on the subject to the landlady. She merely smiled and shrugged her shoulders. She evidently felt that being prosperous and not urgently needing the custom of "*ces Anglais,*" she was not called upon to incur the great outlay which attention to their requirement would involve. My friends, like thousands of other tourists year by year, have gone home to tell these tales to their neighbour—a very bad thing for France from the business point of view. I say nothing about patriotic or other considerations dwelt upon by your correspondents. I beg for the British privilege of concealing my name (when not demanded), and subscribe myself,

Yours truly,
M. B. J.

Fontenay-sous-Bois, Seine.
September 18th, 1913.

To the Editor of The Medical Press and Circular.

Sir,—The strictures of your correspondent on hotel sanitation in France apply with even greater force to the caravanserais of Italy, as I can vouch—unhappily to my cost. Although not a medical man myself, I have a brother and two nephews in the profession, and I take great interest in medical affairs as an educationalist, and rarely fail to read the Medical Press and Circular at my club. In discussing this important subject, one must admit that in most of the leading hotels in Paris, along the French Riviera, and in all the famed health resorts of France, sanitation has made great strides during the last few years and is well nigh perfect, much of it having been carried out by English specialists. The filthiness, apart from its attendant dangers to health, of the old system of water-closets causes an involuntary shudder when one remembers, as I have reason to do, what it was forty years ago. But it is still as abominable in some of the Italian hotels which I visited in the early part of the present year; and the complaint of your correspondent—which, according to my experience, would be exceptional in these days in France—becomes the common lot of unfortunate travellers in beautiful Italy. Of course, I could readily name certain hotels whose proprietors have put their houses in order and are reaping the just reward of their enterprise, but it is with the hope of stimulating to immediate action other centres through which so many English tourists and patients pass in search of health and recreation that I make my criticism of the country at large. These hoteliers have been warned, sometimes at the cost of a life through the obnoxious drainage, and it needs but the constant exposure in leading medical journals to compel, what should not need exhortation—the protection of life and health by them.

I am, Sir, yours truly,
A Member.

Travellers' Club.
September 20th, 1913.

MEDICAL MEN AS DENTISTS.

To the Editor of The Medical Press and Circular.

Sir,—Too many medical men are unaware of the fact that by virtue of being registered medical practitioners they are entitled, under Section 3 of the Dentists Act of 1878, to use the title "dentist."

The current "Educational Numbers"—Medical and Dental—announce that "In addition to the longer courses of hospital [dental] attendance, courses of six months' duration will be given to surgeons about to join the Army and Navy, or to practise in the Colonies or remote districts." I would suggest, Sir, that if a sufficient number of the 41,587 registered medical practitioners are encouraged to take a "six months' course," as they are invited to do by the official educational institutions, such proceeding would materially assist in lessening the wail that there are only a few thousand dentists to meet the demand of "20 millions" of mouths requiring attention in the United Kingdom. Or it might help the Chancellor of the Exchequer, who is "deeply interested" in the subject (*vide* your reference to the matter in your comment *re* "Panel Dentists" in last week's journal).

I am, Sir, yours truly,
Myles Keogh,
Registered Medical Practitioner.

Dublin,
September 17th, 1913.

[It is, of course, well known that medical men have a right to practice any branch of surgery they choose. To practice dentistry efficiently, we believe that much more than six months' special study is required—Ed. M.P. and C.]

PANEL DENTISTS.

To the Editor of The Medical Press and Circular.

Sir,—Is there not some mistake in your annotation under this heading in your issue of September 10th?

After your often-repeated and amply-justified remarks anent unregistered dental practice, I find it difficult to understand your reference to a meeting of advertising and unregistered persons practising dental surgery. I fancy you must have intended to write "British Dental Association" in place of "Incorporated Dental Society." Surely you do not wish to suggest that the members of this body of unqualified persons should be placed one and all upon the suggested dental panel.

I enclose my card, and am

Yours truly,
M.R.C.S.Eng.

London.
September 13th, 1913.

[The writer of the article was unfortunately misinformed as to the nature of the Society in question. It would be disastrous to the future of the National Insurance Act were any branch of unqualified medical practice to secure recognition in any shape or form.—Ed M.P. and C.]

"A NEW REMEDY FOR ALOPECIA AREATA."

To the Editor of The Medical Press and Circular.

Sir,—In the leaderette headed "A New Remedy for Alopecia Areata," which appeared in your issue for August the 20th, you mention the success that Dr. Whitfield has obtained by correcting errors of astigmatism in this complaint. If my memory does not mislead me I believe this is not the first time that a connection between the two has been announced.

You further ask how the fact of an uncorrected error of refraction can affect the nutrition of the scalp. The explanation, I think, lies in the determination of the necessary nervous trophic influence, determining the nutrition of the scalp being starved, owing to the need for all the spare nervous output being required to "run" the ciliary nerves and ciliary muscles of the eyes. That the nerve supply can be diverted to the eye away from its proper "routes" is commonly seen in ophthalmic practice. I remember a severe and progressive case of ptosis, which completely cleared up by correcting the strain on the superior rectus of the same eye. In this case the energy ran down the one branch of the superior division of the third nerve, that to the superior rectus, whilst it neglected that to the levator palpebræ.

The mention of scalp affections reminds me of the case of a clergyman who complained that whenever he preached he felt an acute pain on the very top of his head. He considered it a "nervy" symptom arising from the excitement of preaching. The cause was more probably neuralgia from nerve starvation, as he became entirely freed when his fairly high degree of long-sighted astigmatism was corrected.

Such cases tend to prove how impossible it is to "beat the boundaries" of the effects which *unconscious* eye strain can and do produce.

I am, Sir, yours truly,
A. A. Bradburne, L.R.C.S.Ed.
30 St. Anns' Street, Manchester.

[If our correspondent refers again to the paragraph he will find it expressly states that a host of diverse diseases have been attributed to errors of refraction. The association of alopecia areata with that kind of defect is by no means a new observation. Whether it is concerned as cause and effect has not been established or otherwise; in other words, it remains a theory.—Ed. M.P. and C.]

ENGLISH RAILWAY SANITATION.

To the Editor of The Medical Press and Circular.

Sir,—The letter of "Anglo-Indian" in your issue of the 10th renders a valuable public service in drawing attention to the deplorably backward state of what may be briefly described as "railway sanitation." I trust some of your correspondents will furnish us with the legal aspect of the case. It is to me inconceivable that a medical officer of health should not be able to visit and control the sanitation of any railway in his district. The vagaries of British law, however, are too notorious to make one certain of anything except its uncertainty. I once saw a station in which only one of several closets was availtble (a penny-in-the-slot opening): the door was permanently open, the water flush absent, and the pan choked to the top with excreta. It is open to question, by the way, whether the railway company is not bound by law to furnish closet accommodation to passengers free of cost. The subject deserves to be thoroughly threshed out in the interests of the travelling public.

I am, Sir, yours truly,
Viator.

Surbiton.
September 20th, 1913.

OBITUARY.

DR. G. P. TENNENT, OF GLASGOW.

We regret to announce the death of Dr. Gavin Paterson Tennent, who died on the 13th inst., at 159 Bath Street, Glasgow, aged 67. The deceased, who was one of the best-known physicians in Glasgow, qualified M.B., C.M. in 1867, becoming M.D. in 1870 and F.F.P.S.Glasg. in 1875. After holding various resident hospital posts in Glasgow he assisted the Professor of Materia Medica—the late Dr. J. B. Cowan—and during these twelve years he frequently fulfilled all the duties of the Chair during the enforced absence of the Professor owing to illness. In 1874 he was appointed Physician to the University Lying-in Hospital and the Dispensary for Diseases of Women, and in the same year, when the Western Infirmary was opened, he became Physician to the Dispensary. When the Freeland wing of the infirmary was completed in 1881, Dr. Tennent was elected a full physician in charge of wards, and he continued in office till 1896, when he resigned owing to the increasing demands made upon his time by the claims of his consulting practice. The directors, in order to mark their appreciation of his 22 years' service to the hospital, made him the first honorary consulting physician to the institution—an honour of which he was justly proud. Dr. Tennent possessed in an exceptional degree the power of inspiring confidence in his patients, and the public will remember him as one of its most trusted consultants. Yet it must not be forgotten that both in the University and in the wards of the Western Infirmary he was a most successful teacher. He attracted students by his earnestness and thoroughness. His lectures were always carefully prepared, and were marked by rare clinical insight.

As a man Dr. Tennent was large-hearted and generous, and he performed numerous benevolent actions of which no one will ever know the full extent. He may truly be said to have lived for his work, and consequently he found little time for social and other recreations. He was, however, very fond of travelling, and spent most of his summer holidays abroad. Dr. Tennent was unmarried, and was the last surviving member of his own immediate family. His death has removed one of the most prominent and highly respected members of the medical profession.

DR. F. W. FORBES ROSS.

The death occurred on the 18th inst. of Dr. Frederick William Forbes Ross, M.D., F.R.C.S., of New Cavendish Street, W. The deceased was educated at the University and the Royal College of Surgeons at Edinburgh, and at University College and Middlesex Hospitals, London, and was a gold medallist and senior prizeman in the subject of anatomy at the Royal College of Surgeons, Edinburgh. In 1893 he obtained the M.D. degree at Edinburgh with honours, while ten years later he became F.R.C.S.Eng. He was also D.P.H., R.C.P.S.Lond. Dr. Forbes Ross was formerly a civil surgeon to the London Guards' Hospital, surgeon to the Kensington General Hospital, and had also held surgical appointments at the Samaritan Hospital, North London Hospital for Consumption, and the Children's Hospital, Paddington. His contributions to medical literature were many, and the subjects varied, and he was the inventor of several useful surgical instruments and appliances. These included a safe blunt hook and crotchet, an inhaler for the continuous administration of oxygen, a "traveller" for opening deep-seated liver and other abscesses, and a retainable bull-dog crushing clamp for a solitary hæmorrhoid.

DR. E. J. NIX.

We regret to announce the death of Dr. Edward James Nix, of Weymouth Street, London, W., who died on the 11th inst., aged 69. Dr. Nix, who studied at Charing Cross Hospital, qualified as L.R.C.P.Edin. and L.S.A.Lond. in 1872, became L.R.C.S.Edin. in 1874, and M.D.Brux. in 1877. He was well known as a medical practitioner in the West End, being Physician to the All Saints' Children's Hospital, Margaret Street, and to the St. Elizabeth's Home for Incurables, Mortimer Street. He was formerly a member of the Council of the Medical Society of London, Vice-President of the Medical Defence Union, and President of the Brussels Medical Graduates' Association. He was also a Fellow of the Royal Society of Medicine and a Vice-President of the Medical Society of London.

DR. DUNCAN McCALLUM.

The death occurred, in the Western Infirmary, Glasgow, after a somewhat protracted illness, of Dr. Duncan McCallum, the esteemed Medical Officer of Tarbolton and Annbank. Dr. McCallum was in his 45th year, and was a native of the parish of Morvern, Argyllshire, and previous to taking up his residence in Ayrshire he was the Medical Officer for the united parish of Pennygown and Torosay, Isle of Mull. In Tarbolton he built up a large and successful practice, and in addition held several important public appointments, the duties of which he discharged with skill and untiring energy. He was a graduate of Glasgow University, and devoted a considerable amount of his time to diseases of the ear, having obtained practical instruction at Guy's Hospital.

Dr. McCallum, in addition to his medical duties, took the greatest interest in the breeding of Highland ponies, and was a recognised authority on horses, and in cattle shows his decision as a judge of horses always met with unanimous approval, both of farmers and horse breeders. Dr. McCallum is survived by a widow and young family.

NEW PREPARATIONS.

"KEPLER" MALT EXTRACT WITH GLYCEROPHOSPHATES.

We have received a sample of the well-known "Kepler" Malt Extract with Glycerophosphates issued by Messrs. Burroughs Wellcome and Co. Each fluid ounce contains .4 gr. of calcium glycerophosphate, and of potassium, sodium and magnesium 2 gr. each. For these "Kepler" malt extract forms an appropriate and palatable vehicle, having as well a definite food value of its own. This preparation has been found beneficial in enfeebled conditions of the nervous system from exhaustion, as well as in such apparently diverse conditions as anæmia, urticaria, and incontinence of urine. In osteo-malacia and rickets the calcium salt is valuable, and in the treatment of epilepsy by means of a salt-free diet, the administration of glycerophosphates, in conjunction with bromide, is strongly recommended by authorities. In this elegant preparation the glycerophosphates are presented in an agreeable medium, which is itself an easily assimilable nutrient, claimed to be capable of aiding amylaceous digestion. To this extent the therapeutic value of the glycerophosphates is considered to be enhanced.

MEDICAL NEWS IN BRIEF.

Enteritis at an Infirmary.

The Public Health Committee of the Camberwell Borough Council have had under consideration the outbreak of enteritis among the children in Southwark Infirmary, East Dulwich Grove, which is near a railway siding where the Council deposit their dust and refuse for removal to trucks. In a report presented to the Committee, Dr. Francis Stevens, the Medical Officer of Health, states he has been in the neighbourhood of the siding in all conditions of wind and weather and has never noticed any nuisance, neither has he received any complaints, except in February, 1906, of an accumulation of rubbish before May this year. The reloading of the dust was carried on within a short distance of the houses in Melbourne Grove, the platform of East Dulwich Station, and a much-used omnibus and tramway route on one side, and on the other side of the station was Constance Road Workhouse. He pointed out that a return showed that when there was much enteritis in Southwark Infirmary there was always a considerable number of cases elsewhere in the borough. He asked the committee to bear in mind that because the handling of dust takes place near an institution where children have been attacked by enteritis, it is by no means necessarily a case of cause and effect. There were many other factors to be weighed and excluded before they could accept what was on the evidence supplied nothing but theory.

The Public Health Committee endorsed Dr. Stevens's opinion that the deaths in Southwark Infirmary were not attributable to the causes assigned. They were of opinion that every precaution was taken to prevent any nuisance arising from the removal of dust at the siding, and also drew attention to the fact that the removal of manure was a private matter, and in the hands of the railway company as common carriers. In view of the unjustifiable attacks made upon the Council, they recommended that the Local Government Board be asked to hold a public inquiry into the whole matter. The letter of the Local Government Board suggesting that the Council should discontinue the use of the siding for the loading of refuse has been considered by the Works Committee. They report that they have given instructions for every possible care to be taken in the handling of the refuse, and have requested the railway company to ensure that all loaded trucks are removed each night as usual.

Pictures for London Hospitals.

Mr. Otto Gutekunst, senior partner in the firm of Messrs. P. and D. Colnaghi and Obach, has recently presented to King Edward's Hospital Fund for distribution to hospitals about 300 fine and artistic enengravings by and after great old and modern masters which he had framed for the purpose. The pictures have been distributed by the fund amongst the larger London Hospitals and, to judge from the letters of thanks which have been received, Mr. Gutekunst's gift is very highly appreciated.

Death of a Famous Surgeon.

From Lyons comes the news of the death, at the age of 67, of Professor Antonin Poncet, the famous surgeon, who was one of the most remarkable figures in French scientific circles. Professor Poncet saw the assination of President Carnot at Lyons by Caserio in 1894, and took the great responsibility of attempting to save Carnot by performing a vital operation. Without using chloroform, for the wounded man was greatly enfeebled by the hæmorrhage, he made an incision and tried to check the flow of blood which poured from a huge wound in the liver. The attempt was unfortunately in vain. Apart from his actual surgical work, Professor Poncet won fame through his curious historical researches and studies on the illnesses from which Napoléon, Richelieu, Rousseau, and other great men suffered.

Assault on a Medical Man.

Dr. H. P. Jelley, of Hackney, well known as the "threepenny doctor," was the complainant in a case that was heard last week before Mr. d'Eyncourt at North London Police Court, in which William Lambert (38), billposter, and Frederick George Ford (46), porter, were charged with having damaged Dr. Jelley's premises at 172 High Street, Homerton, Lambert was also charged with assaulting William Daymon, a motor-bus driver, and Dr. Jelley.

It was stated by Dr. Jelley that on Wednesday night he heard a scuffle and ran out, and saw Lambert strike one of his patients in the jaw and knock him down. The prisoners were sticking bills on the witness's window. When the witness stated that he would take the address from the bill Lambert seized him by the neck and tried to throttle him.

Mr. d'Eyncourt: Are you a qualified doctor?

Dr. Jelley: Yes.

Lambert denied that he tried to throttle the doctor.

Mr. d'Eyncourt: The marks of your fingers are still on his collar.

Lambert: He wants a new collar. (Laughter.)

Mr. d'Eyncourt stated that there was no doubt that the bill had been taken out to post on Dr. Jelley's premises. Ford was fined 5s. and 10s., and Lambert was ordered to pay 10s. and 30s. costs.

Alleged Infirmary Scandal at Brentford.

It is reported that at a meeting of the Brentford Guardians last week, conditions of certain wards in the Infirmary were reported which, in the words of a medical man, were calculated to "manufacture disease."

Col. Carr Calthorpe said that owing to the want of adequate accommodation many duties in the Union Infirmary which should be performed in private had to be performed in the presence of other patients. He gave a very unpleasant description of the conditions, concluding:—"This is no fancy picture, but a plain statement of facts as they existed in June." He also quoted a letter in which Dr. Williams, Chairman of the Infirmary Committee, is alleged to have admitted that all kinds of septic conditions from throat and blood poisoning were treated in the general wards, and that patients were lying cheek by jowl to the danger of the ordinary cases. The possible consequences, he added, were something too terrible to contemplate.

It was decided that the Infirmary Committee should confer with the medical staff, in order to improve the isolation of infectious cases and the segregation of severe surgical cases.

Dr. Williams said that the Committee had to administer the infirmary as provided by the Board. The infirmary was a magnificent building, but was so absolutely lacking in the essentials for the treatment and care of the diseased that the diseases could not be satisfactorily dealt with, and instead of curing disease the conditions positively manufactured disease, owing to the lack of means of segregation.

SUMMARY OF RECENT MEDICAL LITERATURE ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

Miners' Nystagmus.—Pollock (*Glasgow Med. Journ.*, September, 1913) gives an interesting account of the case of a patient who suffered from miners' neurosis, and who came under observation before the nystagmus was fully developed. Three such cases had been demonstrated at the Oxford Ophthalmological Congress last summer, and the question was discussed whether the disease can be present without the nystagmus. Hemeralopia, night blindness, and photophobia were severe in these cases without nystagmus. Twitching of the lids was present in each case, and one had nodding of the head, and another had twitching of the neck muscles. Butler, who showed the patients, considered that the muscular twitching and tremor were the essential symptoms in the cases. Pollock's patient had been a mine manager for some years, during which time he was constantly in the pits. He complained of severe vertigo, of being dazzled by lights, and of staggering when in the street after dark. He also complained of hemeralopia. The vertigo came on at all times, but especially on coming into the light. Careful search failed to elicit any nystagmus and the optic nerves were normal. Pollock considers that while the question as to whether the disease can occur without nystagmus must still remain open, yet that there must be a stage of the disease prior to the development of the nystagmus, and it is of the greatest importance that the disease should be recognised in this stage. The symptoms presented by the patients whose cases have been recorded are almost entirely subjective, and it is difficult therefore to accept these cases as coal miners' neurosis. Pollock's patient, however, had no suspicion that his condition was associated with a coal mine, and he could not have had the slightest advantage in considering that he was suffering from such a condition. On the whole matter Pollock comes to the following conclusions:—The absence of light is the chief factor in the causation of miners' nystagmus. Coal gas, hydrocarbons from the lamps, and astigmatism are probably secondary agents. The myopathic theory of the late Simeon Snell has now been abandoned. Nystagmus is the most important, but not the only symptom in a complex neurosis. Three cases have been published, and to these a fourth is added of the disease occurring without nystagmus. The opinion is advanced that these cases represent the stage prior to the development of nystagmus. Evidence is brought forward in support of the view, published five years ago, that the lesion is situated in the cerebral centres, most probably in the nucleus of the third and associated nerves.
K.

Local Anæsthesia for the Nose and Throat.—Davis (*Post-Graduate*, August, 1913) discusses this subject and comes to the following conclusions:—Successful local anæsthesia depends not only upon the drugs employed, but the method of application. Where mucous membranes are concerned, and cocain-adrenalin is applied superficially, the secret of safety and efficiency is in having the surfaces clean and dry, in using a small amount of a saturated solution, and immediately before and after operative procedures douching the parts with warm, sterile, normal salt solution. K.

Hair-Ball in the Stomach.—Hood and Ritchie (*R.A.M.C. Journ.*, September, 1913) record the case of a girl of seven years of age who was admitted to hospital on account of acute abdominal pain and constipation. The parents stated that the child had always had a "weak stomach," and four and a half years ago her mother had noticed that she had developed an abnormal appetite, eating almost anything she could lay her hands on, such as pieces of string, tags of blankets, and large amounts of her own hair. This abnormal appetite had, to the best of the mother's belief, disappeared, and for over two years nothing abnormal had been seen in the child's stools. Up to within a week of her admission to hospital the child appeared well and took her food regularly, but since that time she would eat nothing. On examination of the abdomen, an ill-defined tumour could be felt in the epigastric region. The diagnosis of hair-ball was made, and this was proved to be correct by subsequent operation. The child made a good recovery. K.

Urinary Antisepsis.—Jordan (*Brit. Med. Journ.*, September 13th, 1913) reports the results of his investigations on the value as urinary antiseptics of (1) hexamethylinetetramine and its derivatives (urotropin, helmitol, cystopurin, etc.), (2) sandalwood oil, (3) salicylic and benzoic acids, (4) boric acid, (5) uva ursi and arbutin. He grows the organisms in the urine itself, comparing their behavious in urine after taking the drugs to that in normal urine. The effect of acidity and alkalinity of the urine on bacterial growth was tested by taking acid sodium phosphate (NaH_2PO_4) and potassium citrate (Na_2HCO_3) respectively by the mouth. Staphylococci grow more readily in alkaline urine. In spite of what is said to the contrary, B. coli grow almost as well in alkaline as in acid urine. Hexamethylinetetramine is not itself antiseptic, but acts by producing formaldehyde in the urine; this only takes place in acid urine, the drug being inert in alkaline urine. The degree of antiseptic power is proportionate to the acidity, and where this is normal or higher the drug is far the most efficient of all urinary antiseptics. There is no evidence that helmitol, utramine, hetraline and cystopurin behave differently in the urine, though they do in the test tube. Sandalwood oil is a bad general antiseptic, but appears to have a specific action on streptococci, which may apply to cocci generally. It is of some use in alkaline urine. Benzoic and salicylic acids are very similar in action. Both are fairly efficient antiseptics in urine, but are of little use in alkaline urine. Boric acid is an efficient antiseptic. Its action is unaffected by alkalinity, so that it is the most efficient drug in the case of alkaline urines that we possess. Uva ursi is quite a good antiseptic. The writer draws the following practical deductions from his investigation:—(1) The use of urotropin (together with acid sodium phosphate, which should always be given with it) as a prophylactic before any operation or procedure where the urine may become affected is of the utmost value, since if the urine is clean and highly acid, and sufficient urotropin is given in small doses to keep it constantly present, the urine will not support the life of any organism. (2) Urotropin should only be given when the urine is, or can be made acid, otherwise it is inert. It should never be given with potassium citrate in B. coli infections. (3) Where the urine is undergoing ammoniacal fermentation in the bladder, bladder washes, or some operative procedure, will always be the most important part of the treatment. The best drugs to use are boric acid in large doses, uva ursi, and possibly sandalwood oil. (4) Sandalwood oil is always worth trying in a cystitis due to streptococcus alone. (5) When prescribing acid sodium phosphate, it is well to write the chemical formula (NaH_2PO_4) to avoid dispensing mistakes, and to remember that high acidity of the urine is more efficacious than large doses of urotropin.

NOTICES TO CORRESPONDENTS, &c.

☛ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Reprints.—Reprints of articles appearing in this Journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

Contributors are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 8, Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

P. S. (Acton).—The composition of the atmosphere varies within certain limits. The three chief constituents are oxygen, nitrogen and argon. In the light of modern science we must also add helium, neon, krypton and xenon. Further, there are varying quantities of aqueous vapour, carbon dioxide, hydrogen dioxide, ammonia, and ozone, as well as hydrogen sulphide, organic and inorganic particles of various kinds floating in suspension.

TRANSPARENT ZOOLOGICAL AND ANATOMICAL SPECIMENS.

Visitors to the Museum of the International Congress of Medicine (Department of Museum Technique) could hardly fail to be impressed with the striking results obtained by Prof. W. Spalteholz, of Leipsig, for showing the skeleton, muscles and viscera through the skin of anatomical and zoological specimens, "as in a good skiagraph." The importance of the method for scientific investigation is evident. The study of the centres of ossification is rendered quite easy and the minutest ramifications of the bloodvessels can be readily followed. The specimens can be prepared to show all that a perfect X-ray photograph can show and more, because they reveal the details of structure of the various organs and the plastic effect of their relations. We understand that the patent for the method has been lately acquired by the Odol Chemical Works, 59-63 Park Street, Southwark, S.E. The process should be one of great interest to all curators of pathological museums, as well as to students of anatomy and pathology.

Dr. R. T. (Suffolk).—An inebriate retreat must be licensed by the county or borough within which it is situated, and at present there are 19 of them at work, capable of accommodating 566. Every licensed retreat must have a medical officer attached thereto, and medical treatment, including the administration of drugs when necessary, is essential to the proper control of a retreat. Further information may be obtained from the Report of the Inspector under the Inebriates Acts, 1879 to 1900 for the year 1911, not long since issued.

F.R.C.S.Ed. (London, N.).—It has been shown, according to Dr. Frederick B. Power, that the wheat germ contains the following substances:—Choline, betaine, allantoin, cane sugar, dextrose and raffinose, in addition to sitosterol. The amount of fatty oil obtained in a recent investigation was equivalent to about 7 per cent. of the weight of the material employed.

Appointments.

Burke, M., M.B., B.Ch., R.U.I., Certifying Surgeon under the Factory and Workshop Acts for the Skibbereen District of the county of Cork.

Challenor, Lionel, M.R.C.S., L.R.C.P.Lond., First House Surgeon of the Leicester Royal Infirmary.

Charles, S. F. A., M.D., B.Ch.Dub., Certifying Surgeon under the Factory and Workshop Acts for the Lisbellaw District of the county of Fermanagh.

Garvin, S., M.B., B.Ch.Edin., Certifying Surgeon under the Factory and Workshop Acts for the Clonavaddy District of the county of Tyrone.

MacNaught, W. W., M.B., B.Ch.Glasg., Indoor House Surgeon at the Glasgow Maternity and Women's Hospital.

Murdoch, John, M.B., Ch.B.Glasg., F.R.C.S.Edin., One of the Medical Referees under the Workmen's Compensation Act, 1906, for the Sheriffdom of Fife and Kinross, to be attached more particularly to the Dunfermline with Kinross District.

Reid, D. W., L.R.C.P. and S.Edin., L.F.P.S.Glasg., Outdoor Surgeon to the Glasgow Maternity and Women's Hospital.

Ritchie, T. C., M.B., B.Ch.Edin., Indoor House Surgeon at the Glasgow Maternity and Women's Hospital.

Sharpe, C. G. Haye, M.B., Ch.B.Leeds., Ophthalmic Surgeon to the Luton Education Committee.

Wade, E. W., M.D., B.Ch.Dub., Certifying Surgeon under the Factory and Workshop Acts for the Harleston District of the county of Norfolk.

Vacancies.

Ayr District Asylum.—Junior Assistant Physician. Salary £140 per annum, with board, lodging, and laundry. Applications to Medical Superintendent.

The Hospital, Newark-upon-Trent.—Resident Medical Officer. Salary £100 per annum, with board, lodging, and laundry in the Hospital. Applications to Hy. Crampton, Secretary.

Kettering and District General Hospital.—Resident Medical Officer. Salary £100 per annum, with board, residence, etc. Applications to J. Stauyon, Hon. Secretary, 3 High Street, Kettering.

Hospital for Consumption and Diseases of the Chest, Brompton.—Resident Medical Officer Salary £200 per annum, with board and residence. Applications to the Secretary.

York Dispensary and Maternity Hospital.—Resident Medical Officer. Salary £140 per annum, with board, lodging, and attendance. Applications to Joseph Peters, Secretary, 4 New Street, York.

Liverpool Stanley Hospital.—Senior Resident Officer. Salary £125 per annum, with board, residence, and laundry. Applications to Frank White, Hon. Secretary.

Royal National Hospital for Consumption and Diseases of the Chest on the Separate Principle, Ventnor.—Assistant Resident Medical Officer. Salary £100 per annum, with board, lodging, washing allowance in the Hospital. Applications to the Secretary, 18, Buckingham Street, Strand, London, W.C.

Township of Manchester.—Assistant Medical Officer. Salary £110 per annum, with rations, furnished apartments, fire, light, washing, and attendance. Applications to J. Macdonald, Clerk to the Guardians, Poor-law Offices, New Bridge Street, Manchester.

Warrington Infirmary and Dispensary.—Junior House Surgeon. Salary £120 per annum, with furnished apartments, maintenance, and laundry. Applications to J. H. J. Hampson, Secretary.

Parish of St. Giles, Camberwell.—Assistant Medical Officer (Infirmary). Salary £150 per annum, with apartments, board, and washing. Applications to the Medical Superintendent of the Infirmary, Brunswick Square, Camberwell.

Births.

Broadbent.—On September 15th, at Muswell Hill, N., to Dr. and Mrs. Reginald Broadbent (*née* Annette Stanley)—a son.

Cawston.—On September 14th, at Brecon House, Wantage, the wife of A. E. Cawston, M.R.C.S., L.R.C.P., of a daughter.

Longstaff.—On September 15th, at Burley, New Forest, to Dr. and Mrs. T. G. Longstaff—a daughter.

Marriages.

Depree—Willey.—On September 16th, at the Cathedral, Exeter, Hubert Templer Depree, M.B., B C.Cantab., of 65 Portland Court, W., and Guy's Hospital, London, son of Alderman F. Templer Depree, J.P., and Mrs. Depree, "Newlands." Exeter, to Lilian May, eldest daughter of the late H. A. and Mrs. Willey, Pennsylvania Park, Exeter.

Foster—Seabrook.—On September 16th, at Brockworth Church, Gloucester, Dr. John J. Foster, of Churchdown, to Violet Maud, eldest daughter of Rev. J. H. and Mrs. Seabrook, of Brockworth Vicarage, Gloucester.

Porter—Cockell.—On September 16th, at St. Philip's Church, Dalston, Dr. James Houston Porter, of Queen's Road, Dalston, elder son of Mr. James Biggs Porter, of the Inner Temple, and Mrs. Porter, to Katie Marjorie, elder daughter of Dr. Frederick Edgar and Katie Cockell, of Holly Lodge, Forest Road, Dalston.

Deaths.

Graham.—On September 20th, Eleanor Parkhurst Graham, wife of Dr. Graham, of Kingsdon, Somerset, æt. 78.

Hutton.—At Harrow-on-the-Hill, suddenly, of heart failure, David Mount Hutton, M.D., of Birkdale, Lancashire, in his 44th year.

Phillips.—On September 10th, at Inverness Terrace, Bayswater, W., Dr. Alexander Phillips.

Murray.—On September 16th, at a nursing home in Newcastle, George Campbell Murray, L.R.C.P. and S.Edin., L.F.P.S.Glasg., of 37 The Avenue, Durham.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVII. WEDNESDAY, OCTOBER 1, 1913. No. 14.

NOTES AND COMMENTS.

Southwark versus Camberwell.

THE Local Government Board has not so far intervened seriously in the dispute between the Southwark and the Camberwell Guardians. It will be remembered that some weeks since a number of deaths from enteritis were reported in the Southwark Infirmary. The outbreak was attributed by the Superintendent of the Institution to infection conveyed by flies from various railway trucks laden with refuse within a stone's throw of the Infirmary. The refuse belonged to the next parish, Camberwell, which has made light of the matter. The Local Government Board was appealed to, as it had been before the outbreak, but has done nothing more than write a few official letters and send an inspector to look into the facts. The Board has written to the Camberwell Guardians as follows:—"The Board are advised that the evidence does not suffice to show that the cases of enteritis, which have unfortunately occurred in the Infirmary belonging to the Guardians, were caused by the refuse, but the Inspector reports that the arrangements for dealing with the refuse are unsatisfactory and at times they give rise to nuisance. Having regard to the proximity of the Infirmary and other institutions, the Board suggest that the Borough Council should discontinue the use of this siding for the transhipment of refuse from the carts to railway trucks. The Board would be glad to learn at an early date what other arrangements have been made for dealing with the refuse."

There they are and there they remain.

THE tone of this official communication is delightful. The Camberwell Guardians have evidently appreciated its sweet reasonableness, for they have done nothing so far to store their rubbish away from their neighbours' Infirmary. We regret to say that their Medical Officer of Health has strengthened their hands by the following report in which Dr. F. Stevens, the Camberwell Medical Officer of Health, stated that the nearest point of any of the Infirmary wards to the dust-track siding was seventy yards; and the furthest distance that he has ever detected the slightest smell of dust to the leeward of the discharging carts is roughly about sixty to seventy yards, and that only when a very strong wind was blowing towards him, and dust disposal was in active progress. He further stated that when there was much enteritis in the St. Saviour's Infirmary there was always considerable prevalence elsewhere in other parts of the borough; that on the grass and young shoots of the bushes and small trees growing close to the Infirmary wall there was no evidence of dust; and that he had seen members of the staff sitting outside in the open air between the trucks and the Infirmary itself, apparently suffering no inconvenience. The Committee endorsed the opinion of Dr. Stevens that the deaths at the Southwark Infirmary were not attributable to the causes assigned, and, in view of the attacks made upon the authority, recommended that the Local Government Board be asked to hold a public inquiry into the whole matter. As regarded the foregoing report, it avoids the crucial point, namely, that the infection was alleged to have been carried by flies. There is scientific reason to believe that an outbreak of enteritis could be caused in that way. There are the flies, the refuse in the trucks, the outbreak and the deaths, and, we may add, there are the Local Government Board and the Camberwell and Southwark Borough Councils. How long is this farce to continue?

Dust Theory to be Sifted.

THE fallacy, if we may be allowed to say so, of the report of Dr. Stevens is that the dust was not carried far from the railway trucks, whereas infectious disease is due to invisible germs and not to visible dust. Moreover, his contention avoids the main issue raised by Southwark, namely, that the enteritis was due to contagion carried by flies. The Camberwell Medical Officer of Health, however, may have been misreported. Anyway, his Council, by 43 votes to 6, have given him a full opportunity of further investigation by the following resolution:—"That inasmuch as the Guardians of the Southwark Union have failed to prove to the satisfaction of the Local Government Board that the cases of enteritis among the children patients of their infirmary were caused by the refuse in the trucks at the East Dulwich station goods siding, this Council is of opinion that it is incumbent upon them as the public health authority of Camberwell to investigate thoroughly the whole of the circumstances connected with the matter with a view of discovering the real cause or causes of the outbreak and of recommending what future measures should be taken to prevent the occurrence of such epidemics in this and similar institutions situate in the borough, and that the Medical Officer of Health is instructed to carry out such investigation and empowered to call in any expert assistance he may deem necessary for the purposes of such investigation, and, further, that the Guardians of the Southwark Union be informed of the above resolution and asked to afford facilities for this investigation by supplying the Medical Officer of Health with all facts and figures bearing on the subject which their Medical Officer may possess, and that a copy of this resolution, together with the report of the Medical Officer of Health for Camberwell on the allegation of the Southwark Guardians, be forwarded to the Local Government Board."

LEADING ARTICLES.

THE FUTURE OF THE BRITISH MEDICAL ASSOCIATION.

AT a comparatively early stage of the dispute between the Government and the medical profession over the national insurance legislation, it was remarked in these columns that Mr. Lloyd George had split the profession from one end to the other. The full effect of that cleavage has been most acutely felt by our only great organisation, the British Medical Association. The dissensions within that body, both before and after the passage of the Act, were attended with demonstrations of extreme partisanship in a degree hitherto unknown to any large section of the profession. A sort of climax came with the acceptance of an important post on the Insurance Commission by Mr. Smith Whitaker, the Medical Secretary of the Association, and a number of resignations took place. It is generally understood that recently a sort of anti-climax has been reached by the reversal of the policy of the Association which officially declared the panel service to be derogatory to the profession and against the public interest. The second crisis, or sub-crisis, is said to have been accompanied by the tendering of a considerable number of resignations. It is the work of the anti-panel party in the profession, namely, those who adhering to the early policy of the Association set forth in the famous cardinal principles have declared war against the Act and its upholders. The hostility of this somewhat forlorn faction has been crystallised into a formula by the Wandsworth Division of the Association in the following resolutions:—"This meeting of the Wandsworth Division of the B.M.A. is of the opinion that the present pro-panel attitude of the Association is reacting detrimentally to the interests of the members of the profession in general and in particular to the interests of non-panel practitioners, and approves the action of all such members in resigning." This resolution was proposed by Mr. Edwin Smith, seconded by Dr. Barton, and carried by 21 to 14. Were a spirit of the kind denoted in such a declaration at all general the days of the Association might be looked upon as numbered. It is difficult to believe, however, that any large proportion of members will be found ready to subscribe to tactics that may be best described as unwise and disloyal; unwise because they are aimed at legislation which there is not the least prospect of revoking, and disloyal because it amounts to a deliberate and spiteful attempt to wreck an Association to which they belong. Such a resolution renders the resignation of its supporters a foregone conclusion. The retention, indeed, of members holding such views would endanger the existence of any association however necessary its purpose and strong its policy. It may be hoped, however, that the cabal is extreme in proportion to its numerical weakness and to the futility of its foolish partnership. That the British Medical Association has its defects is to say that it is still passing through early stages of its evolution. That it is the only great representative organisation yet possessed by the medical profession is equally true. In it lies the principle of democratic representative control, albeit overlain and obscured at times by the provisions of a cumbrous constitution. With the Association rests the present and future prosperity of generations of medical men, whose interests demand the protection that can alone be gained from a body that has virtually adopted the principles, if not the name, of trades unionism. The Association will doubtless emerge from the present crisis with added wisdom gained from recent experiences. That certain financial reforms and economies will be needed may be inferred from the proposal of the representatives at Brighton to raise the subscriptions to two pounds per annum. The Council will act wisely by taking members into its full confidence and by setting its face resolutely against that internal faction and cabal which have always been the bane of medical corporations. In an association like that under notice the Council should above all things endeavour to rule in accordance with the wishes and the interests of its main body of members, rather than to play the part of puppets in the hands of wire-pullers. Were an illustration needed, one need only revert to the melancholy spectacle afforded a few years ago when one of the highest officials of the Association ran deliberately counter to a warning notice printed week after week in the *Journal* against accepting posts in the Hampstead Hospital. Recriminations, however, will serve no better purpose than the wrecking tactics of the non-panel section. For the present it behoves every member of the British Medical Association to support the Council in their endeavour to tide over what appears to be a somewhat difficult situation, although, let us hope, not hazardous enough to justify the name of a "crisis." The loss of this great organisation would be irreparable, and it is unthinkable that because of their disapproval of a portion of the policy of the Council any considerable majority of members would tender their resignations. After all said and done, it should be remembered that representatives are elected by members, and are all, therefore, subject to removal from their representative position. The wisest course for members to pursue for some time to come is—to use an Americanism—to "sit tight" and possess their souls with patience for further developments.

THE ALLOCATION OF FUNDS FOR INSURED PERSONS NOT ON THE PANEL.

THE administration of so complicated an Act as that which deals with National Insurance was, humanely speaking, certain to be attended with various difficulties and anomalies. The idea of the accumulation of a vast sum of unallocated insurance money in the hands of the Commissioners, however, would hardly have presented itself to the most imaginative and far-seeing of Mr. Lloyd George's critics. That unexpected event has nevertheless happened in London, and its solution has a definite bearing on a similar problem in other parts of the Kingdom. In the metropolitan county there are some 1,488,000 insured persons, and out of these about 400,000 who on April 24th last had not selected the practitioners by whom they desired to be attended. Under the regulations made by the Insurance Commissioners they should have joined the panel by the middle of January, and, failing that, they were to be assigned to practitioners by local insurance committees. The latter step, however, was not taken, owing to the pressure of clerical and other work already thrown on the committees. The upshot of the matter is that in September there is still a small army of insured persons unattached to any particular panel, and for whose medical benefit the County of London Committee held in its hands at the end of the September quarter the large sum of £105,000. Various attempts have been made by the Council to solve the difficulty. Early in the year a circular was issued to insurance committees suggesting that, instead of allocating, say, John Brown and Mary Robinson to Doctor X, 14s. should be paid in respect of two persons not named and unknown to him, the persons in question being unaware that they, in their turn, had been assigned to Doctor X. The action thus suggested raised a doubt as to its legality in the minds of some members of the insurance committees. The matter was submitted to an eminent counsel, Mr. Danckwerts, K.C., who answered to the effect that the doctors on the panel had made a distinct contract for distinct persons and distinct fees, and the committee therefore had no right to hand over to them any money other than that for which they had contracted. The matter, of course, cannot be permitted to stand thus. In a discussion upon the point, Dr. H. H. Mills expressed his natural resentment against certain words used by Mr. Danckwerts, namely, "the committee is not entitled to make presents nor to distribute largesse amongst the panel doctors." Any suggestion of the sort is grotesque in view of the exacting nature of the services rendered and of the meagre remuneration tendered. The situation, however, must be faced. The State has handed over £105,000 to the Insurance Commissioners for the medical benefit of some 400,000 who have not formally joined any particular panels. Had they required medical service there is little reasonable doubt that they would straightway have placed their names on the list of the local panel doctor. In fact, this £105,000 has been a premium of health and sickness insurance to which the doctors on the panels are entitled morally, if not in the strict interpretation of the law. The best thing that could happen, if the Government wish to retain their amicable relations with the medical profession, will be to legalise the distribution of the unallocated money forthwith. A short enabling Act when Parliament meets would at once solve a difficulty that, left untreated, may end in sheer disaster. It is difficult to think that a man of the political acumen of the Chancellor of the Exchequer will fail to recognise the wisdom of a prompt and generous settlement of the point. This unallocated money was provided by the State for the services of medical men. If diverted from that original intention by no fault of the medical profession, but owing to defective administration of the Act, it may be asked pointedly what the Government propose to do with the money. Medical men have heard so much as to the solid financial advantages accruing to them under the Insurance Act that they will watch the issue of the dispute as to the unallocated payments with especial interest and curiosity.

CURRENT TOPICS.

A Coroner on Laudanum.

At a recent inquest held at Platt Bridge, Wigan, upon a five-weeks-old infant, some curious facts were disclosed relative to the sale of laudanum and its administration to young children. The unrestricted sale of "soothing syrups," some of which contain the tincture of opium, is, unfortunately, still responsible for a large number of infant deaths. In the case referred to, a mixture containing laudanum and aniseed was sold by a chemist to a little girl of eleven, but though the bottle was distinctly marked "Laudanum. Poison. Dangerous to Children," the mother gave two eggspoonfuls to her infant because it had "cried ever since it was born." It appears that the caution on the label was unheeded because the mixture resembled that sold by a woman in the neighbourhood, from whom it could be freely obtained by anyone. In the evidence it was stated that twopennyworth of the mixture would contain thirty minims of aniseed and eighty minims of laudanum. The County Coroner, Mr. S. Brighouse, in his address to the jury, lamented the state of affairs that rendered it possible for child life to be so endangered. After the jury had returned a verdict of "Death from narcotic poisoning by misadventure," the parents were recalled and the Coroner addressed some pertinent remarks to the mother about the folly of giving children such dangerous concoctions, instead of going at once to a qualified medical man. The objectionable practice of popping dirty "comforters" into babies' mouths as soon as they begin to cry was also strongly condemned. Altogether, Coroner Brighouse may be congratulated upon his outspoken remarks, for unless the Legislature step in and render it an offence to give laudanum to children under a certain age, except under medical supervision, this sort of thing will still continue.

The Physiology of Micturition.

It has been commonly supposed that the desire to micturate is dependent upon the stimulation of the sensory nerves of the posterior urethra, resulting in the reflex contraction of the involuntary muscle of the bladder wall and consequent relaxation of the internal sphincter. The neuro-muscular mechanism of micturition consists of nerve-fibres derived from the sacral plexus and the inferior mesenteric ganglia which innervate the detrusor and sphincter muscles. Finger has expressed the view that the posterior urethra becomes an integral part of the bladder when the latter is distended, supporting his contention by the fact that the length of the urethra is from 2 to 3 cm. shorter when the bladder is fully distended than when only moderately full. A series of interesting observations has been made by Drs. Alexander A. Uhle, and W. H. Mackinney, of Philadelphia, who record their results of skiagraphic examination of the urinary bladder in the *Urologic and Cutaneous Review* (Technical Supplement). They followed the work of Leedham-Green, using a 25 per cent. solution of cargentos (a colloidal silver oxide) which is non-irritating and casts a dense shadow. It is stated that the X-ray photographs show no evidence that the prostatic urethra becomes a portion of the fully distended bladder, a sharp line of demarcation existing between the two structures. The results of these studies appear to show that the internal sphincter muscle is the one which closes the vesical orifice, and that the posterior urethra never becomes a vesical neck. The portion of the bladder wall known as the trigone is the most sensitive of all, the fundus next, and the lateral walls least of all. The desire to micturate would, therefore, appear to be due to the distension of the bladder musculature and is not dependent upon the entrance of urine into the posterior urethra.

Learning and Teaching.

Lewis Carroll used to address the Magdalen Tower as "tu doces" because he said it looked like one. This is rather intricate abuse, as there is nothing inherently insulting in an accusation of pedagogy. In medicine at any rate it is not true that he who cannot do, teaches. It more often happens that he who can do, cannot teach although he tries to. Our profession as a whole is better at absorbing knowledge than at secreting it in a form suitable for the use of others. That comes from the nature of our calling. Our *technique* must be learnt by doing, not by being told how. "Knowledge by suffering entereth." And the suffering must not be all on the part of the material. Our teaching bodies have not quite got hold of this. They still attach an undeserved importance to lectures. A lecture is, for the student, a thing to get credit for. It consists in the spectacle of an eminent practitioner appearing before benches of crowded inattention to declaim, out of the richness of his experience, interesting or uninteresting things. It is usually considered an inevitable waste of valuable time, and although we should not like to go so far as this, we are forced to admit that there is too much of the infant school method of teaching in the medical curriculum. It has been said that a teacher's success is measured by the degree in which ideas come not from him but from his pupils, which, being interpreted, means that men should not be taught, but should be made to learn.

After this the Deluge.

A lady in Brooklyn, U.S.A., is reported to have recovered damages from an actor-manager because she wept continuously for over a year after seeing his company play *East Lynne*. It was not the sugary sentimentality of the piece alone that caused this long-lived lachrymosity, but a sequence of events directly attributable to it. Real wet tears of pure emotion filled her eyes as she left the theatre, and she fell over a hole in the stair carpet. Her lachrymal apparatus was injured and she kept up an accurate imitation of Niobe till the case was settled. It is a sort of poetic justice. People go to see sloppy plays in the sure and certain hope of enjoying an orgy of cheap emotion. They like to lose control of themselves in the theatre and to stain the place with hypocritical tears. With this example before them they may be more careful and will, perhaps, realise the wisdom of looking before they weep.

A Mosquito Campaign near London.

During the past summer the inhabitants of the suburban districts bordering upon Epping Forest have been troubled with mosquitos to such an extent that it was felt advisable to call a conference of the various health authorities concerned, with a view to inaugurating a campaign against the nuisance. Mr. W. E. Rowe, of the Chingford Urban District Council, presided over the gathering, which was held at the London offices of the Essex County Council last week. The neighbourhood has been visited and thoroughly explored by Dr. E. Halford Ross, associated with the John Howard McFadden Research Fund at the Lister Institute of Preventive Medicine, whose expert medico-entomological knowledge has thus been placed at the service of the public. The insects found in the district are the common domestic mosquitos or gnats which have been so prevalent in different parts of England during the summer and are almost ubiquitous in Europe. In certain parts of Chingford it was said to be impossible to remain out of doors after tea time, and windows had to be closed. The species found in the district bit only in the evening and at night, and they seemed particularly venomous from an hour after sunset to an hour before sunrise. The eggs of these insects are laid on the nearest water, especially on domestic water collections, such as water butts, though in the forest itself there are a few larvæ-containing pools. Happily, the species of mosquito responsible for all the trouble does not convey disease from one human being to another, but its bite is frequently followed by cellulitis and septic poisoning. According to Dr. Ross's estimate, the cost of an anti-mosquito campaign would not be large, so that it is to be hoped that the suggested remedial measures may be carried out without delay.

Dirty Dublin.

In the week ending September 20th there were, in the city of Dublin, 22 deaths from diarrhœa and enteritis in children under two years of age. All residents in Dublin have noticed the exceptional plague of flies this autumn. A connection between the high mortality and the large number of flies is not fanciful. The Medical Officer of Health for Dublin admits the relation, and in letters to the press warns the public of the necessity of killing flies, and of protecting foods from their visits. As far as we can make out, this is as far as the health department goes in the matter. Malaria has been stamped out in many previously pestiferous regions, not by the slaughter of individual adult mosquitos, but by destroying their breeding grounds. A similar course must be followed in the case of flies. Flies must be exterminated by preventing their production. Unless this be done, we can hope for little improvement in the rates of infant mortality in our big cities. In Dublin, while the health department puts a price on the head of the individual fly, the cleansing department, by neglect of its primary duty, maintains the richest of breeding grounds. Heaps of rubbish lie not only in the back lanes and courts, but in the very streets. Decaying vegetables and fish offal lie for days in the gutters of the streets. In some of the street markets vegetables are exposed for sale lying in the very gutter, without the protection even of a newspaper. The writer has seen a dog emptying his bladder on a bundle of rhubarb exposed for sale on the bare pavement. This is the food on which the poor of Dublin are fed.

Mussels and Health.

Epidemics of typhoid fever have been frequently traced to the consumption of mussels as well as to other shellfish. Cases of so-called "mussel-poisoning" have also occurred from time to time as a result of eating mussels which have undergone a certain amount of decomposition. The exact nature of the poison thus produced is still unknown, but it is probably a chemical substance elaborated by the vital activity of bacteria derived from their sewage-contaminated surroundings. This substance was regarded by Brieger as a ptomaine, to which he gave the name of *mytilotoxin*. In most of the recorded outbreaks of mussel poisoning the onset has been rapid, with vomiting, dyspnœa, difficulty in swallowing and speaking freely, spasms, and lack of co-ordination of movement. Some interesting facts relative to the consumption of mussels and their relation to health are mentioned by Dr. Niven, in his annual report on the health of the city of Manchester. Thus it is stated that in 108 of the 242 cases of typhoid fever registered in 1912, mussel eating was probably the cause of infection. It is recorded that the Saturday night's consumption is more plentiful than at other times in the week, and that, because drink had often been indulged in, the mussels were eaten after the closing of the public-houses. The influence of intoxication or semi-intoxication is said to have been considerable, because stale mussels are less easily detected when drink has been indulged in to excess. The practice of steaming the mussels has not proved of much protection to the consumer, because sufficient time is seldom given to the process. Dr. Niven is of the opinion that if the sale of uncooked mussels were prevented and the shellfish adequately cooked before sale, the enteric incidence would be greatly diminished. Further investigation appears still to be needed as to the actual facts with regard to infection of mussels by the typhoid bacillus, especially in the direction of obtaining full and careful case histories.

A New Tuberculosis Danger.

The paths of infection leading to the human body are indeed manifold. No sooner is one danger detected and dealt with than another half score spring up in its place. The tubercle bacillus, it has long been known, may come to unhappy man in a variety of guises. It may be mingled with the bloom of hothouse grapes, or with rich milk and alluring cream, or be inhaled into the air passages born on flimsy and invisible aerial rafts. Commonly it is conveyed in the imperfectly cooked flesh of tuberculous animals. A hitherto unsuspected source of danger has been recently detected by the Medical Officer for the Port of London, who has recently called special attention to the condition of tongues imported in a frozen condition from South America. An examination was made of the glands at the root of the tongue, and as a result 533 out of 12,800 tongues were found to be diseased. "The deposit of tubercule in the gland in many instances was so extensive," says the Medical Officer for the Port, "that it is obvious that the animal from which the tongue was taken must have shown signs of tuberculosis elsewhere. The glands in the tongues, in the majority of instances, had not been examined at all, and had not been even exposed. I recommend that these facts be reported to the Local Government Board, and to the Government of the Argentine Republic." Anyway, it is comforting to know that in this case, at any rate, the science that has exposed the danger has at the same time shown how it can be avoided.

PERSONAL.

H.H. Prince Alexander of Teck will distribute the prizes to the students of the Royal Dental Hospital of London and London School of Dental Surgery on Tuesday, October 7th, at 5 p.m.

Dr. M. J. Johnstone, of Brecon, has been appointed Tuberculosis Officer for the County of West Sussex.

Dr. H. S. Raper, of Toronto University, has been appointed Lecturer in Physiological Chemistry in the University of Leeds.

Mr. D. Priestley Smith, M.B., B.Ch.Birm., has been appointed Assistant Surgeon to the Birmingham and Midland Eye Hospital.

Mr. T. Harrison Butler, M.D., B.Ch.Oxon., has been appointed Assistant Surgeon to the Birmingham and Midland Eye Hospital.

Dr. F. J. Waldo, J.P., Coroner for the City of London, has been appointed a Warden of the Worshipful Company of Plumbers.

Mr. Alan H. Todd, M.B., B.S., B.Sc.Lond., F.R.C.S.Eng., has been appointed Surgical Registrar and Tutor, and Staff Anæsthetist at Guy's Hospital.

It is announced that Dr. W. A. Renner, of Sierra Leone, is about to retire from the Colonial Service, having been connected with the Medical Department for thirty years.

Mr. F. Montague Miller, M.R.C.S., J.P., late of 14 Arden Road, Church End, Finchley, N., twice Mayor of Hackney, who died on August 15th, left estate valued at £1,073.

Dr. J. Mitchell Bruce, M.A., M.D., F.R.C.P., will deliver the Harveian Oration at the Royal College of Physicians of London on Saturday, October 18th (St. Luke's Day), at 4 p.m.

Sir Ronald Ross, F.R.S., will preside at the lecture on October 7th, by Dr. D. E. Anderson, to inaugurate the sixth session of the Y.M.C.A. free weekly lectures on "Tropical Diseases."

Mr. H. F. Waterhouse, F.R.C.S., will preside at the annual dinner of past and present students of Charing Cross Hospital, at the Adelaide Gallery, Gatti's Restaurant, to-night, at 7 for 7.30.

Dr. F. S. Palmer, M.D., F.R.C.P., will deliver the Presidential Address before the West London Medico-Chirurgical Society at 8.30 p.m., on Friday, October 3rd, in the Society's Rooms, West London Hospital, the subject being "A General View of Malingering."

Dr. J. G. Risien Russell, M.D., F.R.C.P., will deliver the opening address before the North-East London Clinical Society, on October 2nd, at 4.15 p.m., at the Prince of Wales's Hospital, Tottenham, the subject being "Poliomyelitis: New Features of the Affection and Its Diagnosis" (with lantern demonstration).

FRENCH CLINICAL LECTURE

ON THE

OCCURRENCE OF MENINGEAL REACTIONS IN THE COURSE OF POLIOMYELITIS.

By PROFESSOR V. HUNTINEL,

Professor in the Clinique of Diseases of Children, Paris Faculte de Medecine.

[Specially Reported for this Journal.]

In the course of my last lecture, I presented you with a considerable number of observations of meningitis of a benign type. On account of the suddenness of their onset, and the intensity of the reactions which characterise them, those might have possibly been mistaken for cases of cerebro-spinal meningitis; but an examination of the cephalo-rachidian fluid—which is absolutely clear in all the cases, and at the same time containing a fair proportion of albumin, while presenting also a more or less considerable number of leucocytes—tends rather to suggest the idea of the presence of tuberculous meningitis.

Those meningeal reactions disappeared in some days without leaving behind any appreciable traces of their occurrence. Accordingly, I am not quite sure that similar cases have not been confounded with genuine ones of tuberculous meningitis. And, if we have in such instances injected a specific serum or administered some active medicament, what an alluring plea for our adopted medication! Happily for us we know that tuberculosis is not the real cause, any more than was syphilis in other cases; nevertheless, our diagnosis at the onset was decidedly hesitating.

The simultaneous appearance towards the middle of the course of an epidemic of meningeal reactions—if not even cases of true meningitis followed by flabby types of paralysis, transitory or permanent—soon reveals to us the veritable nature of the accidents which had surprised us by their abnormal features. For those cases of slight paralysis of febrile origin, poliomyelitis commencing with meningeal symptoms, acute meningitis, transitory cases sometimes followed by slight motor troubles, appeared in their turn as varying manifestations of the same malady; that is to say, of an infection of which the invisible germ presents a special predilection for the nerve centres.

Instances of cases similar to our own observations have been of frequent occurrence of latter years, but they have often been interpreted in quite different fashion. The oldest and most convincing are those which have been collected in Sweden and in America, where the Heine-Médin disease has presented itself in form of grave epidemics, in the course of which it has been admirably studied.

I can also refer to many important contributions which have been made in France. On July 30th, 1910, M. Netter demonstrated to the Association Française de Pédiatrie the fact that cases of poliomyelitis frequently commenced with a display of meningeal symptoms. In co-operation with his pupil, Tinel, he reported nine observations. In every one of those cases the meningeal reactions had been followed by paralytic troubles, more or less pronounced. MM. Laubry and Parvu presented to the Société Médicale des Hôpitaux, October 21st, 1912, a number of cases in which meningeal syndromes of indefinite nature were accompanied by rachidian polynucleosis in some cases, and in other instances by lymphocytosis.

Of those, the three cases of meningitis accompanied with lymphocytic reaction are of special interest to us. They are, in fact, identical in features with our own; while occurring, indeed, in subjects of somewhat more advanced years—being respectively æt. 19, 17, and 15 years. There was the same febrile onset, occurring in persons in previous enjoyment of perfect health; the same meningeal symptoms; the same characters of the cephalo-rachidian fluid; the same favourable termination of the attack. The question arises: Have we to deal with an infectious disease or with an ordinary or seasonal indisposition? Is it a case of attenuated infection of unknown origin, of which we may not be able at the moment to discover the actual pathogenic microbe? Such are the questions which have been proposed by writers on the subject.

At the same meeting, MM. Rist and Rolland presented five observations of meningitis of benign type, associated with an epidemic history. Those cases had occurred in lads of ages varying between 11½ and 15 years, and they exactly resemble our own. The authors demonstrated satisfactorily that the reports dealt with neither bacillary infections, nor with meningitis; either of the cerebro-spinal type or of the infectious nature which characterises the known types. On the other hand, they were still unable to decide on referring their cases to the compartment of epidemic poliomyelitis; for the good reason that in no one of their patients had the disease been productive of any paralysis which would constitute evidence of implication of the anterior cornua of the spinal medulla. The only difference between the record of their observation and that of ours lies, accordingly, in the interpretation.

M. Widal, in summarising his communication, has stated that over and above the cases of tuberculous and cerebro-spinal meningitis, there are to be met with cases of acute meningeal conditions which simulate either one or the other of those two types of meningeal inflammation, and of which the differential diagnosis can only be established by the revelations of lumbar puncture. Such conditions are frequently observed in way of secondary manifestation in course of the most various infective clinical entities—notably in that of pneumonia and of *la grippe*. They may, however, appear spontaneously and, as it were, on their own account; nevertheless, they are accompanied by general symptoms and the febrile associations which prove that the infection imperatively demands its localisation on the meninges.

At the following meeting, M. Widal—with his pupils, MM. Lemierre, Cotoni and Kindberg—resumed the discussion of those meningeal states. He brought forward six observations derived from the cases of patients, aged respectively 19, 30, 17, 28, and 18 years; that is to say, still young, but of much riper years than our little patients. In some of those, signs of infection were noted: herpetic vesicles, bronchitis, pulmonary congestion, jaundice; and these facts go to prove that the mischief is not absolutely circumscribed within the nerve-centres. In other respects, those cases quite correspond to our own and to those of the authors already cited. But those authorities avow that the ætiology of these cases is still very indefinite. They say that the idea of polio-myelitis must be excluded, as none of the patients presented the slightest trace of paralysis.

MM. Guillain and Ch. Richet (*fils*) have in turn recorded four observations. In these cases the meningeal reactions have been exclusively comparable to those that we have already described; but each has been accompanied by jaundice, which has in every instance presented the characters of a benign infective icterus. The meningeal, urinary, and cardiac symptoms were superadded to the two primordial signs, and thus was demonstrated the existence of a generalised infection.

M. Netter, at each of the two meetings at which his observations were presented, did not fail to signalise and affirm the correlation of those meningeal states with poliomyelitis. In support of this interpretation he has cited the facts derived from the experience of his own practice and those published by other physicians; he insists on the ideas of epidemicity and the frequent co-existence of meningeal lesions with paralytic troubles. Then he returned to that subject at a comparatively recent meeting, that of November 18th, 1910. Having collected a sufficiently large number of observations of those cases of infantile paralysis in which the patient had presented at the onset the characteristic symptoms of cerebro-spinal meningitis, he insists that the Heine-Medin disease is always accompanied by meningeal reaction, at least by the histological basis thereof. In addition to cases of infantile paralysis of meningeal origin, of which he cites very excellent observations, he reports others in which the meningeal symptoms have been followed by paralysis, slight or transitory. In every one of those cases, lumbar puncture has extracted a clear fluid, containing lymphocytes especially. The notion of epidemicity, and the predominance of the cases in the summer months—at a period of the year in which cerebro-spinal meningitis is sufficiently rare—may tend to make us suspicious of many of the cases. Side by side with cases in which the meningeal accidents were followed by lasting paralyses, with atrophy and reaction of degeneration, he has noted others in which the paralysis has been but slight and of short duration. He affirms that those cases should be regarded as attenuated types, and that their occurrence suggests that we should acknowledge the existence of incomplete varieties in which the clinical tableau is circumscribed by the meningeal symptomatology. We ourselves accept this interpretation absolutely without reserve. The slight and transitory paralytic phenomena which were noticed in three of our observations, and which, indeed, might very well have passed unperceived, do not permit us to entertain any further doubt regarding the poliomyelitic nature of the majority of the meningeal reactions that we have hitherto observed, although we cannot yet affirm that all of them should be interpreted in this fashion.

This leads me to pass in review the history of a series of meningeal reactions which take place in the course of the various types of poliomyelitis. Those manifestations, sometimes so serious, have been the subject of many investigations in Sweden, America, Germany, Austria and France. The greater number of the resulting publications have had their contents summarised, almost simultaneously, in two excellent theses, one by Mme. Tinfel-Giry and the other by M. Schreiber.

It has now been approximately proved that poliomyelitis—in its epidemic form, and even in its sporadic, that is to say, in its usual type of infantile paralysis—is due to the presence of a germ which we are not able to see with the aid of the microscope, and of which we are consequently unable to recognise the characteristics. The existence of this germ has been placed beyond doubt by the excellent researches of Wickman and of Landsteiner. We sometimes give it the name of "médullovirus." It belongs, as does that of rabies, to the class of filtrable viruses, and, like the latter, it displays a wholly special predilection for the nervous system.

At the Congress of the International Association of Pediatrics (October, 1912), M. Zappert, who has discussed the pathological anatomy and experimental pathogeny of the Heine-Médin disease in a communicated report, formulated the following conclusions.

"Poliomyelitis is an infective disease produced by a figured virus. The existence of this virus has not yet been established by the microscope, but the question has been placed beyond doubt by experiments on animals. The virus seems to enter by the respiratory passages and to be disseminated by the lymphatic channels. It has quite a special predilection for the nervous system. It invades the centres with the greatest rapidity, and especially the spinal cord itself. We again find it in the lymphatic glands, tonsils, and the salivary glands. We have even discovered it outside the living organism *in the dust of a patient's bedroom.*" He admits that the penetration of the meninges is but slight, if we compare the extent of the same to that which has been reached in the spinal medulla, or even in the brain. The virus of poliomyelitis is an agent of infection; with this power it is able to exert its influence, in some instances, upon organs which are usually respected. Doubtlessly it is in this way that we must explain the occurrence of bronchitis, of pulmonary congestion, of digestive disorder, and also the cutaneous phenomena and the jaundice which are displayed by some patients.

Thus the infection, instead of localising itself exclusively in the cells of the anterior cornua of the spinal cord, as was formerly believed, diffuses itself beyond these structures, and often reaches the envelopes of the nerve centres.

At the same Congress, M. Müller also dealt with the poliomyelitis of rabies; he admits the frequency of the abortive forms of the disease, and insists on their importance as being capable of disseminating the disease, and also of conferring immunity. M. Netter has again returned, in connection with these reports, to discussion of the frequency of meningeal phenomena, completely or vaguely defined, in the Heine-Médin disease, and he proposes to treat them by urotropin, which passes readily into the cerebro-spinal fluid.

Accordingly, the meningeal phenomena which occur in cases of poliomyelitis appear to us to have an unquestionable clinical interest; and the observations presented in my last lecture enable me to attack this subject in a medium of actuality. Whenever we have had occasion to make an autopsy of a victim of poliomyelitis there was found a certain degree of meningeal irritation, visible to the naked eye, and readily displayed by the microscope. Some writers affirm that this reaction is the primary one, preceding the appearance of nerve lesions. The infective origin of the disease renders this opinion fairly plausible, but the lesions described are variable. In some cases the subarachnoid space had been invaded by a sanguineous extravasation which extended around the nerve-roots over an area more or less considerable. This is an exceptional feature: it has been found in monkeys submitted to inoculation, but it has also been met with in the human infant. In the usual cases, as met with in man, the macroscopic lesions are not clearly defined; they merely consist of a more or less marked congestion, but the histological lesions are evident. These are characterised by a lymphocytic infiltration, slightly marked in some cases, very much so in others. Distinct patches of leptomeningitis may be found on the spinal cord, or collections of round cells investing the vessels at the bottom of the anterior fissure. The sub-arachnoid space often remains unaffected; it is sometimes invaded by lymphocytes, but it must be noted that there is no exact proportion between the meningeal symptoms and the anatomical alterations clinically revealed by examination of the cerebro-spinal fluid.

The meningeal reactions of poliomyelitis have been noted by both Swedish and American writers. I may cite the names of Medin, Bull, Geirswold and Leegard, Wickman, Lundgreen, Caverly and Macphail, etc. In 1874, Leyden indicated the occurrence of slight degrees of paralysis after meningitis, and pointed out their analogy to those of infantile paralysis. Pierre Marie said: "I am convinced that a certain number of the deaths attributed to meningitis are no other than cases of unrecognised infantile paralysis; cases in which the lesions proved fatal too rapidly to afford the time necessary for development of the complete clinical tableau of that affection." Integrity of the meninges had gradually come to be regarded as a characteristic of infantile paralysis. If a case of poliomyelitis began with meningeal accidents, it was regarded as one of meningitis followed by motor sequelæ. It is only of late years that the frequency of spinal lymphocytosis in the Heine-Médin disease has been definitely noticed, and that we have been able to connect this malady with the meningeal reactions with which it has often been accompanied. Triboulet and Lippmann, Guinon and Paris, Raymond and Sicard, Sicard and Tanon, and many other clinical observers have published interesting cases; some authors have gone further, and even sought to identify poliomyelitis with cerebro-spinal meningitis. Wickman, in 1905, was the first to describe in detail a meningeal form of the Heine-Médin malady, and he showed that a great number of the cases which had been labelled paralysis consecutive to acute meningitis were in reality but examples of poliomyelitis with meningeal reactions. Nobody now disputes the accuracy of that opinion.

It would also seem that meningeal reactions in the course of poliomyelitis have become singularly frequent of latter years. Mme. Tinel-Giry, while admitting those cases only in which the manifestations were distinctly marked, has noticed 24 instances in 102 cases. At present the proportion is probably greater; besides, it varies according to the epidemics.

In the Heine-Médin disease, meningeal accidents which are clinically recognisable may be completely absent; in some cases, on the other hand, they dominate the scene and attract special attention. Their gravity is far from being the same in all, and they frequently proceed in conjunction with paralyses of various extent and duration. We may here follow the example of Schreiber, from whom we are about to borrow largely, in dividing our observed cases into four groups.

The first group includes those of simple, benign meningitis, usually appearing in epidemic form, characterised clinically by sudden onset and by febrile symptoms which approximate them to cerebro-spinal meningitis, while the modifications of the cerebro-spinal fluid, especially the lymphocytosis, rather suggest the idea of tuberculous meningitis. These cases cause serious embarrassment at the onset, as we are unable to interpret them definitely, but they recover rapidly enough. The following are two examples:—

Wickman, in the Swedish epidemic of 1905, noted meningeal symptoms in four children of the same family. This suggested cerebro-spinal meningitis till a fifth child became affected and presented the features of infantile paralysis, which provided a rectification of the diagnosis of the other cases. Zappert saw, in the case of a girl of five, certain serious meningeal phenomena (violent pains, fever, rigidity of the neck, vesical trouble); three days later the lower limbs were affected by paraplegia. Some days after, the sister of that little girl, who was aged 6, presented, in her turn, the signs of meningitis. It was expected that she would also develop paralysis of the lower limbs, but nothing of the kind occurred, and she recovered rapidly.

Most of our observations may be included in this class, and doubtless also those that I cited in the former lecture—of Rist, Laubry, Widal, Guillain and their pupils. Medin has observed similar cases. They have also been met with in the United States, in Germany, and in Austria, especially in the summer months, and they have been specially frequent in the later epidemics. Such cases of meningitis, which are nearly always characterised by spinal lymphocytosis—possibly in certain cases, also by a certain degree of polynucleosis—constitute one of the four abortive types of the Heine-Médin disease which have been described by Wickman.

In some patients the *médullovirus* produces appearances of generalised infection which may easily be taken for those of influenza, especially if there are any bronchial manifestations; in others it develops pains in the limbs and along the spine, which cause a diagnosis of articular rheumatism; in others still it evolves gastro-intestinal derangements, with or without jaundice, of which the true origin may not be remotely suspected, if not associated with nervous phenomena. Those irregular manifestations are grouped in certain instances. For example, we find icterus appearing simultaneously with meningeal reactions; bronchitis or pulmonary congestion may precede infantile paralysis—facts which prove their infective origin. Such ill-defined cases are able to disseminate the infection, and in the majority of instances it is almost impossible to determine their nature. For this purpose it would be necessary to neutralise the virus with the serum of patients and inoculate monkeys therewith—a delicate and expensive test which can be applied only in certain laboratories.

In addition to such cases of benign meningitis, there are fatal ones. The fact, however, is that such are absolutely exceptional, the cure being usually rapid and complete. It is probable that in those malignant cases it is not the meninges alone that are affected, but that the nerve tissue also has undergone profound and selective alterations. The patients are carried away before the paralysis has had time to be established. For example, here is a case recorded by Oppenheim. A child who had come from Paris fell sick at Cologne, and succumbed to hyperacute meningitis. Her sister, aged 9 years, soon after presented meningeal symptoms in turn, but her case evolved as one of infantile paralysis. Zappert cites another. A child of 8 years was suddenly carried off by meningitis. At the same time a child of 4, living in the opposite house, presented a paresis of the left leg; and, in another neighbouring house, a child of 3 was attacked with violent gastro-intestinal symptoms, which were soon followed by paraplegia engaging the lower limbs.

The commonest cases are those in which the meningitis is followed by paralysis, transitory or permanent. Sometimes the paralysis is so slight and transitory that it may be disregarded, of which I have already given you an instance in detail. The following case of Zappert's is a typical one.

Joseph B., aged 9, who was attacked, had a sister, aged 5½ years, who had been attacked fifteen days before with meningomyelitis, with persistent paresis of the lower limbs. On January 2nd, 1909, there was epistaxis, headache, pains in back of neck, and calves of legs, fever, nuchal rigidity. For ten days the child was unable to sit up, as the muscles of the back were paralysed. On the 16th he began to sit up alone in bed; on the 23rd he was well and walked about like everybody else. Another case is mentioned by Triboulet, Harvier and Vaudescal. A child of 6 was brought to hospital. There was a meningeal syndrome of the clearest type—extreme rigidity of neck and trunk, Kernig's sign, lymphocytosis. Six days after the onset, right brachial monoplegia developed, and abolition of all the tendon reflexes was noted. Still this case of infantile paralysis, notwithstanding its startling onset, proved benign and was cured in ten days.

Léon Bernard and Maury have reported two cases: the first was one of meningitis and transitory paresis of lower limbs; the second, meningitis, hemiplegia of the right side, in a baby of 18 months, which proved transitory. The four following are borrowed from Netter:—

(1) Lucienne G., 11 years, attacked on September 28th, 1909, with headache, pain in back, Kernig's sign, and fever. October 2nd: Some meningeal symptoms; vaso-motor line. Lumbar puncture: Hypertension of fluid; no microbes or cell elements; little albumin. October 5th: Paresis of sacro-lumbar muscles and of lower limbs. On the following day the weakness diminished and the patient was able to sit up. On the 8th she felt pains in all four limbs. On the 21st she left hospital, walking well.

(2) Girl of 4½ years. Sudden attack of fever and colic. Third day: Nuchal rigidity and transitory aphasia. Speech restored on following day.

(3) Girl of 6 years. Febrile onset (104°). Nuchal rigidity; then Kernig's sign; meningeal line; some vomiting; constipation. Cerebro-spinal fluid clear. Inability to move limbs or trunk. After three weeks the child began to sit up; by degrees she was able to leave bed, but the limbs remained feeble for a long period.

(4) Boy of 7 years. Same brusque onset; same symptoms; same duration; same termination.

I might multiply such cases; they are, indeed, common enough, and it is probable that in many cases in which attention has been aroused by meningeal symptoms only, partial paralysis, light or transitory, would have been noticed if skilfully sought for. In two of our own cases weakness of the lower limbs was noticed, but this proved so transient that hardly any importance was attached to it. But if we do not notice paralysis, or even paresis in most cases of infection by the *médullovirus* we almost invariably find complete abolition of the tendon reflexes. Between the simple meningeal reactions, the meningitis followed by temporary paralysis, and grave infantile paralysis commencing with meningeal symptoms, there exists an uninterrupted chain of intermediate types. When meningitis is followed by paralytic sequelæ, located in the limbs, we should always ask ourselves whether we are not dealing with a case of poliomyelitis.

Those cases of paralysis which are seen in the course of poliomyelitis of meningeal onset are far from being so benign. Some persist for months, atrophying and destroying many muscular groups. I remember a case of this kind which remains permanently present to my mind—for it was with the patient that I saw Charcot for the last time. A girl of 6 had been attacked by meningeal symptoms which had given great anxiety to her physician, my excellent friend, Dr. Talamon. After some days, paralytic symptoms appeared in all four limbs. I thought it a case of polyneuritis; that was also the opinion of Charcot. The weakness lasted for some months, but it finally disappeared.

Sometimes atrophy of the muscular masses is definitive, as in ordinary infantile paralysis. If I wish to characterise infantile paralysis, as resulting from epidemic or sporadic poliomyelitis, I should say that the latter, more benign in appearance, produce motorial and nutritional troubles much more profound and persistent than do the former, although these attacks are more brusque and more menacing. In the epidemic cases the infection seems to distribute itself over a greater area of the nerve centres; in the sporadic it limits the field of activity, but destroys the cells with which it comes into contact.

There are also cases of paralysis of meningeal origin which rapidly destroy life. Beginning with the lower limbs, the trunk is invaded, then the upper limbs, and at last the bulb itself. Thus arrive troubles of respiration, of circulation, and of deglutition, which make prolonged survival impossible. These ascending paralyses realise the clinical syndrome of Landry's disease. The patients preserve their intelligence to the end. They die of asphyxia, the respiration ceasing during sleep.

The following case was observed in the Enfants Malades (1910), and was published by MM. Nobécourt and Schreiber:—

B. M., æt. 4, was brought to hospital August 31st, 1910, with a diagnosis of cerebro-spinal meningitis. The nucha was, however, flaccid and the limbs swinging. The weakness was nearly complete; there was tenderness on pressure, and a slight diminution to sensibility to pin-pricks. Abolition of tendon reflexes. Presence of meningeal line. Temperature 38.6° (101.5° F. quam. prox.); pulse 134. No oculo-pupillary phenomena. Lumbar puncture: hypertension of cerebro-spinal fluid, clear, albuminous, with some traces of glucose. September 1st.—Paraplegia complete, with flaccidity; the child had great difficulty in sitting up. September 2nd.—Condition still worse; paresis of upper limbs; temperature 103.2°. In the afternoon, increase of paralysis, copious sweating. Intelligence preserved; the child understands, but articulates her responses badly. No Dysphagia. She died in the night. Having gone to sleep, the will—which alone had maintained the respiratory act—was found wanting. The autopsy showed congestion of all the organs. Hæmorrhages, in quantity, found in the sub-arachnoid spaces over the whole length of the spinal cord. Obliteration of the vessels of the dura mater, which were surrounded with numerous mononuclear leucocytes. Leucocytic infiltration, and small hæmorrhagic foci in the grey substance of the cord; slighter lesions in the white substance.

M. Mery has communicated a very similar case. Three others have been observed in the other services of the Hôpital des Enfants Malades.

Is it necessary to multiply examples in order to prove the relationship of meningitis—acute, benign and epidemic—with the meningeal reactions of the Heine-Médin disease to be legitimate? Curable meningitis and poliomyelitis appear at the same periods and in course of the same epidemics. Typical and ill-defined cases alternate in appearance, not only in the same localities, but in the same families. The same sudden and febrile onset; same leucocytic formula in cerebro-spinal fluid; same rapid evolution. Still the demonstration is not complete. There is wanting, in most cases, the proof obtainable by neutralisation of the virus by the serum, and inoculation of the monkey. I shall be surprised if laboratory researches do not succeed in confirming the findings of the clinique.

The study of meningeal reactions in the course of the Heine-Médin disease, which is merely skimmed in this lecture, permits us to offer certain concluding remarks. If the meninges appear undisturbed at the onset of most cases of this malady, in others the paralytic phase is preceded by a more or less distinct meningeal period; besides, indeed, this meningeal period may alone develop, and not be followed by any paralysis. All forms of poliomyelitis—spinal, bulbo-protuberantial, cerebral, or acute-ascending—may begin with a meningeal syndrome. When paralysis appears in succession to meningeal accidents, we have to ask ourselves whether we are in the presence of a case of poliomyelitis which began with a strong meningeal reaction, or a meningitis followed by paralytic sequelæ. If we are dealing with paresis or painful paralysis, extended and flaccid, with abolition of reflexes, and not with a case of paralysis limited to the distribution of one of the cranial nerves, the chances are that the cause is to be sought in the Heine-Médin disease. If the meningitis has been followed by neither paralysis or even weakness of certain groups of muscles the interpretation is more difficult. Let us remember, however, that those meningeal conditions have usually a brusque onset, comparable to that of cerebro-spinal meningitis, while the modifications of the cerebro-spinal fluid suggest those which characterise tuberculous meningitis. In the presence of this clinical paradox it is necessary to remember poliomyelitis, to note with care the absence of all germs from the cerebro-spinal fluid, and carry out experimental inoculations on the guinea-pig. The result of such inoculations must generally arrive too late for the purpose of clearing up the diagnosis, for the patient will have long been cured when the time for sacrificing the animal has arrived. But it will give us at least the opportunity, in doubtful cases, of eliminating the proud supposition that we have cured a case of tuberculous meningitis.

If paralyses supervene, they are usually transitory; they are, however, in some cases, slow to disappear, and in the (happily) exceptional cases they adopt an ascending course which is rapidly fatal. But in such cases the paralytic phenomena follow very closely on the origin of the meningeal manifestations, and the diagnosis is, accordingly, not long left in doubt.

In summarising: the *médullovirus* may be responsible for a whole gamut of misdeeds, from reactions so slight and vaguely defined as to be quite ignored, up to the most formidable developments. When such meningeal reactions, medullary or encephalic, present themselves to you, do not make undue haste to formulate a pessimistic prognosis to which the future will furnish a humiliating contradiction: also, do not believe too readily afterwards that you have arrested the progress of a case of tuberculous meningitis.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Wyatt Wingrave, M.D., Pathologist and Dean of the Central London Throat and Ear Hospital. Subject: "A Consideration of Vaccine Therapy."*

The International Anti-Alcohol Congress was opened last week at Milan. Prof. Marchiafara, Consulting Physician to the Pope, delivered an address upon the progress of alcoholism in Italy.

Owing to delays caused by the recent labour troubles in the building and allied trades, the Committee of Management of King's College Hospital are compelled to postpone the opening of the new buildings fixed for October 1st. A further announcement will be made shortly.

ORIGINAL PAPERS.

THE NAUHEIM TREATMENT IN ENGLAND.

BY LESLIE THORNE THORNE, M.D., B.S., ETC.,
Late Medical Examiner, London County Council Technical Education Board.

THE treatment of diseases of the heart and circulation by mineral baths and exercises has now a well-established position as a therapeutic agent, but it is not yet so generally employed as would be expected when one considers the highly satisfactory results obtained by its use and the wide range of its application. There are still many of the medical profession who do not realise that the treatment can be given in England as successfully as at Nauheim, and who regard it rather as a last resource, when all other forms of treatment have failed, or believe that it is only useful in cardiac conditions in which no valvular lesion is present. The object of this paper is to deal briefly with the various forms of cardiac and circulatory disease which have been successfully treated by the Nauheim methods in this country, and to give one or two examples of such cases.

There is a widespread belief in England that a course of Nauheim baths is synonymous to a course of carbonated effervescing baths, and it is probably due to this erroneous belief that this method of treatment has often been wrongly applied, and has therefore failed to produce a satisfactory result. In many cases of cardiac and circulatory disease the effect of carbonated baths is distinctly injurious, and in all cases it is decidedly unwise to begin a course with this form of bath. The mild thermal baths which are given at Nauheim at the commencement of a course should always be administered at first, and only later on, in a certain number of cases, should carbonated baths be given.

The Nauheim baths produce a dilatation of all the cutaneous capillaries, thus lowering the blood pressure and relieving the heart from excessive work, and thereby enabling it to contract more perfectly and less rapidly, and giving it a comparative rest, so that, as the course proceeds, the muscular tone of the heart is gradually improved, the dilatation disappears, the circulation in all the organs of the body becomes more efficient, and metabolism is quickened, with the result that any toxic material is more easily eliminated, and a more normal circulation is set up in organs which have probably got into a congested and degenerate condition. The patient therefore continues to improve in health for a long period after the termination of the course and, in many cases, does not relapse. When, however, the condition is due to a faulty metabolism produced by a gouty or rheumatic diathesis, a second course of baths is needed after the lapse of a year or eighteen months, and sometimes a third at a later period; but in cases due to acute febrile attacks, including acute rheumatism in children, the patient does not often relapse unless subjected to a second attack of the disease which was the cause of the cardiac mischief in the first place. During the last eighteen years I have treated a very large number of cases in London by these methods, and it is my experience that, if they are properly selected, the results are highly satisfactory and the failures are very few. Most of the cases that come under my observation have been treated by drugs and rest for lengthy periods, sometimes several years, without any material or lasting improvement; indeed, a large percentage of the patients who derive the greatest benefit from a course of Nauheim baths are of that class which do not yield to other forms of treatment.

In selecting cases for treatment by baths and exercises the question of suitability is almost always one of degree rather than of kind, though there are certain forms of cardiac disease which are more benefited than others. It is not possible in the space of this article to give a detailed account of all those conditions which will derive benefit from this form of treatment, but the following short classification may be of help as a guide to those who have no special experience of the range of application of the Nauheim treatment.

The Post-Influenzal Heart, weakened and dilated by the toxins of the disease, and giving rise to symptoms of dyspnœa, palpitation and cardiac pain, and ultimately causing a general invalidism and inability for any work or pleasure, is one which responds rapidly to this treatment. Many cases of this class have been restored to health by a course of Nauheim baths, after long periods of rest and cardiac tonics have produced no material or lasting benefit.

Cases of High Arterial Tension, in which the area of cardiac dulness is found to be enlarged; exhibiting symptoms of dyspnœa, headache, palpitation, cyanosis and general ill-health, will respond well to a course of Nauheim baths, and the blood-pressure will drop from 20 to 40 mm. hg. during treatment, often falling from 170-80 mm. hg. to 130-40 mm. hg., and the troublesome and dangerous symptoms will be relieved for a long period. These cases are usually met with in middle-aged people, but they also occur in the moderately young, especially men who have led a strenuous, sedentary life and are subject to rheumatic or gouty attacks.

Cases of Valvular Disease with Cardiac Dilatation, indicating a weakened and degenerate condition of the myocardium, respond well to the treatment, more especially if high arterial tension is present. In uncomplicated cases of valvular disease with cardiac hypertrophy treatment is not necessary, but it is seldom that a case of valvular disease of long standing with a raised blood-pressure does not exhibit some symptoms of cardiac dilatation and defective circulation, and if these are present they can be relieved by a course of baths more satisfactorily and for a longer period than by any other form of treatment.

When premature cardiac contractions, arising in the ventricles or auricles, are present, causing cardiac irregularities and distress to the patient, it is often found that they gradually decrease in frequence during a course, and that at the end of the treatment a perfectly regular heart's action is established, this being due to the improved nutrition of the conductive mechanism of the heart. Case 1 is a good example of improved conductivity, the result of a course of Nauheim baths.

Cases of Obesity with Fat-clogged Hearts and Raised Blood-pressure are not only greatly improved in health by a course of Nauheim baths, but lose fat steadily both during the course and for some months after; so that a patient weighing 17 stone before treatment will lose about one stone in weight during the course, and will probably have lost another stone three or four months later. The reduction in the weight is, I believe, due to the improved circulation favouring a formation of healthy tissue instead of fat, and to the patient's ability to take more exercise when he finds he can do so without experiencing dyspnœa and cardiac pain. A large percentage of obese persons suffer from dilated, fat-clogged hearts and raised blood-pressure, and no treatment that does not relieve these conditions will do any permanent good. Case 2 is an example of this kind.

Cases of Irritable Heart of a "functional" nature, where no organic lesion is discovered, are often greatly relieved by this treatment, but they are not so certain of improvement as cases where definite dilatation is present.

Cases of Anæmia with Cardiac Dilatation, which do not respond to treatment with iron, arsenic or general hygienics, will often show immediate improvement if a course of Nauheim baths is given in conjunction with other treatment.

It is not advisable to give the Nauheim treatment in cases in which there is general evidence of a broken-down constitution, nor have I found it of much benefit to cases exhibiting auricular fibrillation, or in those in which very advanced degeneration of the vessel-walls is present.

The following examples of cases treated by the Nauheim methods illustrate well the wide field of usefulness of this treatment, as they differ in most details almost as widely as any two cases of cardiac or circulatory disease can do.

Case 1.—A young man, æt. 24, had had a "weak heart" from birth, had always suffered from dyspnœa, palpitation, bad headaches, sleeplessness, and dyspepsia, was unable to go in for sports, was often troubled by severe pain over the cardiac region and a sense of exhaustion; at times he was greatly distressed by marked cardiac irregularity, which gave great discomfort. On examination, the following signs of cardiac disease were present: He was markedly cyanosed, especially the ears and lips, and his fingers and toes were clubbed and blue, his pulse was 94 per minute and markedly irregular. These irregularities were proved by a polygraphic tracing (Fig. 1) to be due to premature ventricular contractions, which occurred about every fourth or fifth beat; the heart's impulse was diffuse and forcible, and the area of cardiac dulness was enlarged (Fig 3 AA). On auscultation a very loud systolic murmur was heard all over the left side of the chest and in the left axilla, its area of greatest intensity being over the upper part of the sternum. The case was undoubtedly one of congenital heart, probably patent foramen ovale, with possibly sub-aortic stenosis.

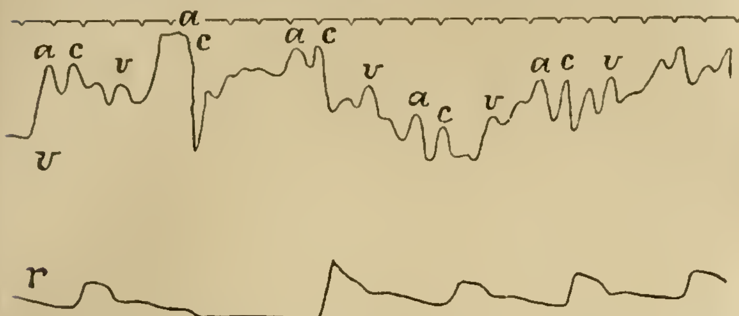

Fig. 1.—Polygraphic Tracing before Treatment, showing example of premature ventricular action. *v* Venous tracing. *r* Radial tracing.

I gave him a course of 24 Nauheim baths, extending over a period of five weeks. His symptoms began to improve almost at once; he slept better and lost the sensations of cardiac irregularities and exhaustion, and towards the end of the treatment he was quite free from dyspepsia and his colour was much improved. At the conclusion of the course his cardiac impulse was less diffuse and less forcible, the area of cardiac dulness was normal (Fig. 3 BB), the murmur was not so loud or diffuse, the pulse was 72 per minute and practically always regular in action, as is shown in Fig. 2, a section of a long strip of polygraphic tracing taken after his course was finished. His blood-pressure was 70—100 mm. hg. during the whole course, and never varied much.

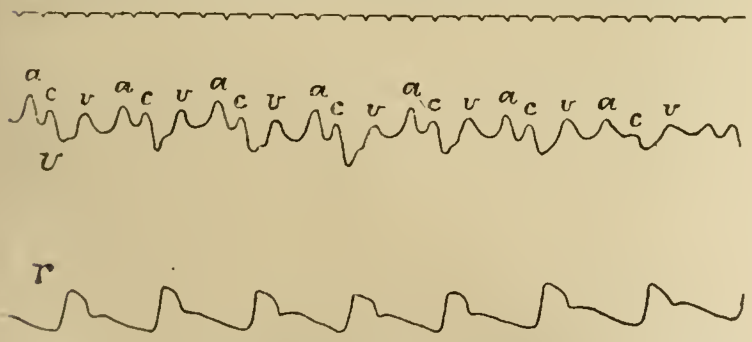

Fig. 2.—Polygraphic Tracing showing regular action of pulse after treatment. *v* Venous tracing. *r* Radial tracing.

Case 2.—The patient, a married woman, æt. 51, who had a very rheumatic and gouty family history, had an attack of rheumatism and sciatica five years before I saw her, since when she had suffered from dyspepsia, palpitation, pain over the cardiac region on walking, shortness of breath, and has been growing increasingly stouter. She had had various treatments by dietary and drugs, but had never got any definite relief from them, and had steadily got worse. When I first saw her, her condition was as follows:—She was a very stout woman, height 5 ft. 3 in., weight 12 st. 6 lb. She was somewhat cyanosed and suffered from dyspnœa on the sightest exertion; her ankles were œdematous. On percussion, her cardiac dulness was found to be greatly enlarged (Fig. 4 AA), and the sounds were so faint they were only just audible at the apex and could not be heard over the base of the heart; the pulse was regular, 82 per minute; the blood-pressure was 90-148 mm. hg., and the urine was normal. I gave this patient a course of 25 Nauheim baths, at the end of which she was able to walk several miles with comfort, whereas for five years previously she had not been able to walk without pain and dyspnœa, and consequently never walked at all. Her dyspnœa was entirely cured and she had no palpitation; her pulse was 76 per minute, her blood-pressure 75—120 mm. hg., and her cardiac dulness was normal (Fig. 4 BB). Although this patient improved greatly in health during the treatment she only lost 5 lb. in weight at that time, but I heard from her four months later to the effect that she had lost 1 st. 3 lb. in weight, and had just taken a twelve miles walk with comfort.

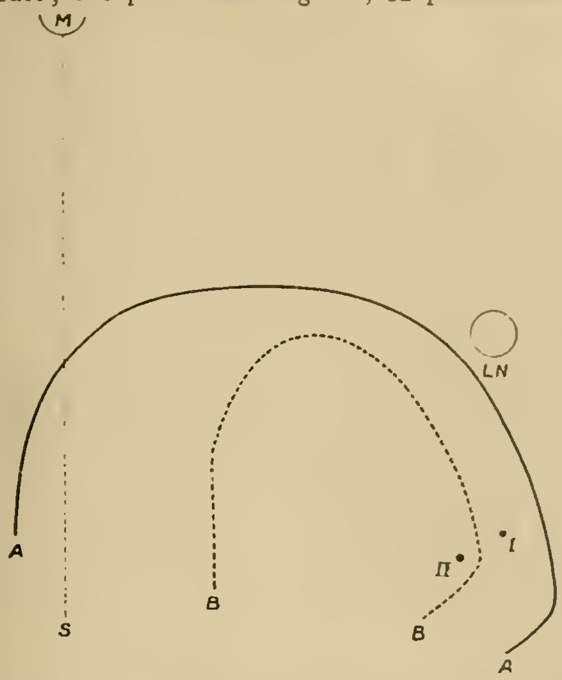

Fig. 3.—AA Area of Cardiac Dulness before Treatment. I Apex beat. BB Area of Cardiac Dulness after Treatment. II Apex beat. MS Mid-sternal Line. LN Left Nipple.

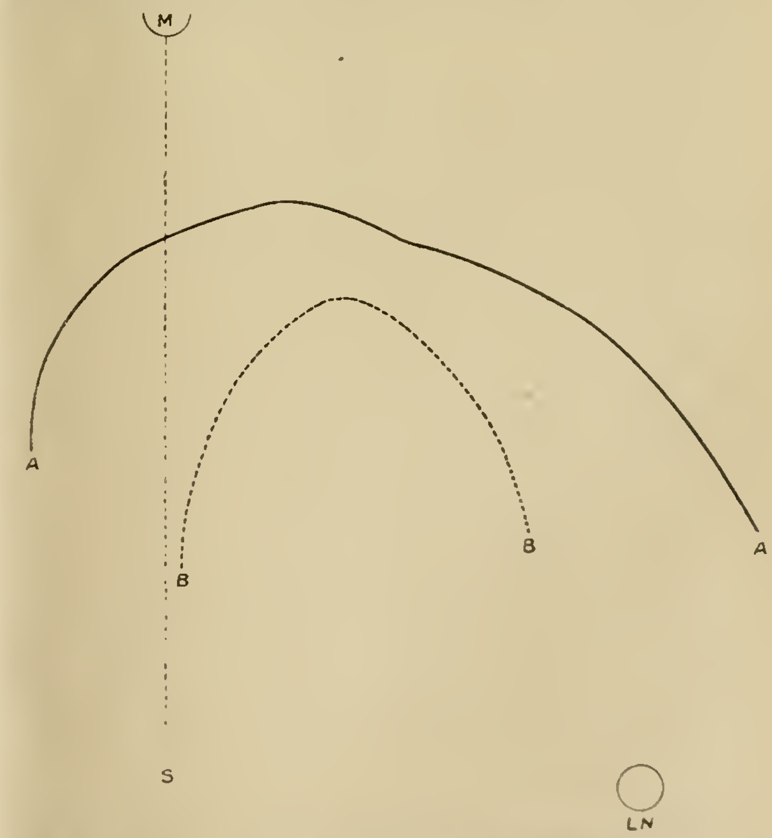

Fig 4.—AA Area of Cardiac Dulness before Treatment. BB Area of Cardiac Dulness after Treatment. MS Mid-sternal Line. LN Left Nipple.

The above case is a typical one of obesity due to defective circulation. The patient no doubt had rheumatic myocarditis during her illness five years before she saw me; this weakened the cardiac muscles and led to dilatation. The raised blood-pressure due to the rheumatic condition led to further strain upon the heart, the circulation was impaired, and fat was rapidly formed instead of healthy tissue, the heart itself becoming hampered by fatty infiltration. No good can be done in cases of obesity of this kind till the heart and circulation are put into proper order. I believe the reason why the weight was not much diminished till some time after the course, was due to the fact that all the organs were so degenerated by the long period of defective circulation that, although the circulation was greatly improved, it needed several months of this improved circulation to restore the organs to a normal condition.

HILUS TUBERCULOSIS (ROOT PHTHISIS). (a)

By R. MURRAY LESLIE, M.A., B.Sc., M.D.,
Senior Physician, Prince of Wales's Hospital; Physician, Royal Hospital for Diseases of the Chest, London.

The object of this communication is to place before the members of the Congress some of the main facts in support of the view that chronic pulmonary tuberculosis in children and in a large proportion of adults usually starts at the root or hilus of the lung and gradually spreads from the hilus towards the periphery. A more detailed account is given in the author's original papers on "Hilus Tuberculosis," published in the *Clinical Journal*, January 22, 1913, and the *Journal of Tuberculosis*, June, 1913.

Hilus tuberculosis includes (*a*) tuberculosis of the hilus glands, and (*b*) tuberculosis of the pulmonary tissue in the neighbourhood of the hilus.

(*a*) Tuberculosis of the Hilus Lymphatic Glands.

The frequency of tuberculous deposit in the tracheobronchial lymphatic glands at the hilus has long been recognised, and, indeed, can be readily understood when the fact is recalled that they are, as Sir Douglas Powell well expresses it, "the dust-bins of the bronchopulmonary tracts," and are also in direct communication with the cervical and abdominal lymphatic systems, and therefore may be infected by way of the tonsillocervical and intestino-mesenteric channels. The bronchial glands are often the first tissues attacked by tuberculosis in early life, and may indeed be the only foci of disease in the whole body. So extraordinarily common are tuberculous foci in the bronchial glands and the surrounding tissue that the majority of all bodies examined post-mortem, whatever the cause of death, present evidence of old-standing disease in these parts. Careful dissection is often necessary to expose to view the smaller indurated, caseous, or calcareous glands situated on the bronchi and below the tracheal bifurcation, where they are often concealed by the overlying hilus tissue, although during life they may have stood out quite clearly in an X-ray photograph as definite rounded dark shadows. It is modern radiography, however, that has revealed how common enlarged and calcified glands are in the living subject. The latter stand out as dark clearly defined areas. Postero-lateral as well as antero-posterior X-ray examinations must be conducted with the object of revealing enlarged glands situated behind the "median shadow" cast by the sternum, heart, and great blood-vessels.

As regards the incidence of glandular tuberculosis, evidence is accumulating that catarrh of the bronchial mucous membrane is one of the most important predisposing causal factors, and in this way may be explained the frequent occurrence of tuberculous adenitis of the bronchial glands as a *sequela* of whooping-cough and measles. Other observers are of opinion that the thoracic glands are more often secondarily involved as the result of buccal (including tonsillar) and intestinal infection. All authorities are agreed that tuberculous disease of the bronchial glands (like that of other glandular tissues) is much more common in children, no doubt owing to the fact which Dr. H. D. McCulloch has recently emphasised—"that a child possesses a conspicuously developed lymphoid and lymphatic system, the highly cytogenous glands of which bear the brunt of the overwhelming microbic invasions to which the sterile tissues of the young child are necessarily exposed in a notoriously microbic environment, and before immunities have become established."

Fortunately there is a marked tendency to spontaneous cure in the case of glandular tuberculosis, as is evidenced by the frequency with which calcified bronchial glands are met with radiographically and post-mortem in cases where there had been no suspicion of any tuberculous disease. At the same time the fact must not be overlooked that the disease may lie latent in the glands for prolonged periods, and may be followed many years later by important and serious consequences.

(*b*) Hilus Tuberculosis affecting the Pulmonary Tissue.

Hitherto the *apex* of the lung has always been regarded as the most frequent primary focus of pulmonary tuberculosis. In 1880 Sir J. Kingston Fowler stated that a spot 1 to 1½ inches below the actual apex was the primary seat of disease in the large majority of cases, and then described a "line of march" spreading in each lobe *from above downwards*. Recent pathological researches, however, in conjunction with radiographic evidence have thrown considerable doubt on the correctness of the apical hypothesis, and on the contrary strongly support the view that the *hilus (root) and not the apex is in the generality of cases the primary focus of disease, particularly in children, and that the "line of march" is from the root to the periphery.* In this connection one might specially refer to the pathological researches of such investigators as K. Preisich and Anthon Ghon, and to the clinical observations of radiographers, notably Dr. Lewis G. Cole, of New York, and Dr. Alfred Jordan, of London. K. Preisich in an article published in the *Weiner Medizinische Wochenschrift*, 1911, states that in children over eight years of age there are frequently found peribronchially disseminated lobular or confluent foci, while there is also found caseous infiltration starting from the hilus and spreading over the entire lobe, probably starting from the hilus glands and extending back along the lymphatics. Dr. Cole, in his excellent paper published July, 1910, in the *American Journal of Medical Sciences*, states, as the result of his radiographic experience, that it will be probably established that all pulmonary tuberculous lesions begin at the root and extend to the parenchyma. Dr. Jordan, whose original communications were published in the *Practitioner* and *British Medical Journal*, in February and August, 1912, states categorically that chronic pulmonary tuberculosis does not generally commence at the apex, but begins at the roots and extends along the branchings of the large bronchial tubes. He believes that the tuberculous process generally spreads by bronchopneumonic extension in the peribronchial tissues, and that these deposits in favourable cases cicatrise into fibrous bands appearing as dark radiating shadows on X-ray examination of the affected lungs. He further believes that the disease reaches the apex by way of the ascending bronchiole, and, when the apex is reached, the disease may there progress rapidly, so that the apex appears clinically to be the chief seat of the invasion, the primary disease at the root being so deeply placed as to escape detection by the ordinary methods of clinical examination. Another English radiographer—Dr. Bythell—goes so far as to state that in children pulmonary tuberculosis invariably starts at the root of the lungs. In a paper communicated to the Royal Society of Medicine in 1913, he stated that out of 300 successive cases of pulmonary tuberculosis in children examined both clinically and radiographically, he had never seen a single case in which the disease had not obviously originated in the hilus of the lung, nor met with one in which the sole or even the primary lesion had been at the apex. Whenever there was found an apical lesion there was

---

(*a*) Paper read before the Section of Medicine, International Congress of Medicine, 1913.

in every case revealed by the X-rays a far more advanced lesion at the root of the lung, which had escaped detection by the ordinary clinical methods of examination, but was clearly indicated by definite mottling and nodules in the region of the hilus.

During the past few years the author has conducted a series of clinical and pathological investigations in conjunction with radiographic examinations, and his results strongly support the contention that chronic pulmonary tuberculosis in the large majority of children and in a considerable portion of adults starts at the root of the lung and involves the central area long before there is any apical deposit. The accompanying radiograms and pathological specimens (here shown) are taken from illustrative cases.

The evidence in support of hilus tuberculosis is threefold—(1) *radiographic*, (2) *pathological*, (3) *clinical*. In no department of medicine has modern (and particularly instantaneous) *radiography* proved of greater value than in elucidating the origin, site and progress of chronic pulmonary tuberculosis. There is still considerable divergence of opinion as to the exact interpretation of the various root shadows and lung mottlings revealed by the X-rays. It is impossible in the space at the author's disposal to go fully into this question, which has been referred to in detail in his published papers already alluded to. The general conclusion is that certain types of root shadows and of grouped mottlings are definitely significant of old or recent tuberculous deposit, which can be readily traced as passing out from the roots into the deeper portions of the lung tissue and extending outwards towards the apex and other portions of the periphery. (Illustrative radiograms here shown.)

The *pathological evidence* of the spread from the hilus is in the nature of the case necessarily scanty. It is rare for patients to die in the early stages of pulmonary tuberculosis when the disease is limited to the root area. In most cases when death supervenes the lungs are generally infiltrated throughout, so that it is practically impossible to tell from the appearances present whether the disease started at the root or the periphery. Still, occasional cases have arisen (and will be forthcoming more and more as time goes on) when the patients have died from some intercurrent disease or complication, and where the pathological evidence has strongly supported X-ray findings. It is not at all uncommon to meet post-mortem with instances of extensive disease more or less limited to the root area, while the apices and peripheral portions of the lungs may be wholly or comparatively free from tuberculous infiltration. (Specimens shown).

The *clinical evidence* of hilus tuberculosis is necessarily also somewhat indefinite. Every physician, however, has had experience of a large number of cases with suggestive symptoms of pulmonary tuberculosis, but no definite physical signs. There may be only a slight cough accompanied by some degree of failure of health. Certain symptoms are suggestive—obstinate dry cough, slight hæmoptysis, tightness in the chest, wheezing (so-called asthmatic) attacks in children, occasional evening rises of temperature, and increased pulse frequency, in conjunction with a varying degree of anorexia, languor, anæmia, debility, and loss of weight. Such symptoms lead one to suspect the existence of some disease in the central portions of the lung adjoining the hilus, which is too deeply situated to produce definite physical signs. Even when there is no change in the percussion note and no marked alteration in the character of the vesicular murmur, one may get in a certain proportion of cases an area in the interscapular region, close to the root of the scapular spine, where one may find some impaired percussion, harsh breathing, prolonged expiration, and increased voice conduction. The presence of persistent rhonchi, particularly if localised, in a patient with failing health often indicates central tuberculosis spreading from the hilus. If such cases are at this stage submitted to X-ray examination characteristic root shadows and mottling are generally extremely prominent, and although at this stage there are generally no tubercle bacilli in the sputum, the diagnosis may be confirmed by tuberculin reactions.

Mode of Extension of Hilus Tuberculosis.

There is considerable divergence of opinion as to the inter-relationship of tuberculous bronchial glands and hilus pulmonary tuberculosis. In a number of cases the infection seems to spread directly to the lungs from the caseous bronchial glands, often apparently by direct contact: it is, indeed, sometimes difficult to determine in a section through the affected lung where the caseous bronchial glands end and where the pulmonary tissue begins. The extension in the large majority of instances probably takes place along the perivascular and peribronchial lymphatics. The author has advanced the view which has since been supported by Dr. Bythell and others, that *the doctrine of the retro-impulsion of lymph goes far to explain the principal phenomena connected with the extension of tuberculosis from the hilus to the periphery.* The retro-impulsion of lymph is now a well-proved phenomenon, due to the researches of Bier, Sir Almroth Wright and others, the back-flow of lymph taking place along the distended lymph channels, the valves of which are no longer competent. It is obvious that the terminal lymph channels discharging into the bronchial glands must contain numbers of bacilli and other bacteria derived from the various portions of the broncho-pulmonary tract. As long as the glands themselves are healthy these bacilli will be adequately dealt with by the bactericidal action of the gland cells. After a time, however, it may be a period of years lasting from infancy to puberty—the bronchial lymph glands by becoming caseous and eventually calcareous not only lose their bactericidal properties but serve to block the lymph stream. As a result the afferent lymphatic vessel walls become distended, particularly at the terminal portions, so that the valves are no longer competent, and a slow backward flow of the lymph with its bacterial contents sets in. Consequently the tubercle bacilli already present in the sluggish backward flowing lymph stream, whether derived from the broncho-pulmonary tract or directly from the caseous glands, filter through the walls of the distended lymph channels and set up a broncho pneumonic process in the surrounding pulmonary tissue. As these inflammatory areas heal up and cicatrise, the terminal lymph vessels become still further obstructed by the surrounding cicatricial tissue, and so the filtering, inflammatory, and healing process is repeated a little further out, the extension taking place slowly and steadily from the root towards the periphery and mainly in the tissue immediately surrounding the bronchi and pulmonary vessels. The whole process is, as a general rule, so extremely slow (in the absence of accidental contingencies producing autogenous infection) that there is, as a rule, plenty of time for protective antibodies to be formed in the system, and for immunity to be gradually established. In this way the hilus tuberculous infiltration in the great majority of cases entirely heals and cicatrises, while the increased phagocytic and bactericidal efficiency of the blood and tissues prevents the access of fresh, living bacilli from without. This theory of immunity affords a rational explanation of the fact that although according to Hamburger and Monti 94 per cent. of the population under 14 years of age have actually been infected with tuberculosis, fully 80 per cent. of these never exhibit symptoms or signs of manifest disease.

It is quite otherwise in advancing cases, where there is a constant liability to accidental contingencies involving autogenous infection, particularly in the later stages. If the disease progresses, the apices may become affected either by a gradual direct extension from the hilus along the peribronchial and perivascular lymph channels, or independent foci may be formed, due to aspiration broncho-pneumonia (*e.g.*, by bronchial embolism of infected particles detached from an open lesion), or as the result of autogenous blood infection. *Hilus tuberculosis in the early stages is a "closed" disease, the bacilli being confined to the hilus glands and the peribronchial pulmonary tissue.* In the latter stages accompanied by caseation, ulceration of the walls of the bronchi and bronchioles occurs, with the result that tubercle bacilli are discharged into the lumen of the bronchi, where they mix with the bronchial secretion which is partly expelled in the expectoration and partly aspirated in the act of forced inspiration into the remote terminations of the bronchioles, where the bacilli may directly induce foci of bronchial pneumonia.

In a certain proportion of cases there is little doubt that *primary peribronchial deposit* takes place as isolated foci as the direct result of the lodgment on and penetration of the bronchial mucosa by bacilli derived from without in the act of inhalation. These foci are probably, however, comparatively few in number, as the great majority of the inhaled bacilli are passed on by way of the lymphatics to the root glands. Each such focus may be of considerable importance, as, however quickly it may heal up, it may, by providing a suitable culture nidus in living tissue, serve to materially reinforce the virulent activity of the originally inspired bacilli, few of which probably in their original active state succeed in surviving the passage through the various lines of defence on their way to the root glands. It is the perivascular and peribronchial interstitial rather than the pulmonary tissue proper which is mainly affected in this very early stage, when the lymphatic exits to the glands are freely open and the glands themselves functionally active. The finer radiating hilus streaks seen with the X-rays even in healthy children may have originated from a fibrous transformation of this small-celled perivascular and peribronchial connective tissue infiltration. On the other hand, the mottling, blotching, and other evidences of gross hilus lesions are probably later phenomena, associated with stagnation, or backward flow of lymph consequent on the blocking resulting from glandular disease, whether active or quiescent.

Amongst the important *sequelæ* of hilus tuberculosis may be mentioned *chronic fibroid phthisis*, which is in reality its final stage. *Tuberculous pleurisy*, whether dry or accompanied by sero-fibrinous effusion, may also be traced to the same cause: Sir William Osler indeed states that, in almost every instance of tuberculous pleurisy, there are tuberculous foci in the bronchial glands, and it may be added that in every such case radiography will reveal definite hilus changes. The author, while house physician at the Brompton Hospital for Consumption, noted the large proportion of patients with physical signs of chronic pulmonary tuberculosis, who gave a history of an attack of pleurisy six, eight, or more years previously. The exact number of years represents the time required for the slow spread of hilus disease from the root to the periphery of the lung.

A large proportion of cases of so-called *asthma in children* may be traced to reflex or direct irritation from enlarged, often tuberculous, bronchial glands, and peribronchial thickening and infiltration. The lungs of such children suffering from asthmatic attacks if examined by X-rays generally present unusually well-marked hilus shadows, and not infrequently dark discrete areas indicating calcified glands. In adults also asthmatic attacks are undoubtedly in some instances associated with hilus tuberculous thickening. A certain proportion of cases of *acute miliary tuberculosis* are the direct result of systemic infection due to penetration of branches of the pulmonary veins by caseating bronchial glands.

As regards the *diagnosis of hilus tuberculosis*, it should be made a definite rule for all children and young adults with persistent cough accompanied by anæmia, lassitude, pyrexia, or other signs of failing health, to be submitted without delay to an X-ray examination. The value of early diagnosis of hilus tuberculosis cannot be over-estimated. The late Dr. Gee was of opinion that "If physical signs of Pulmonary Tuberculosis were present the probabilities were against complete recovery; but if the disease were detected before this there was hope that it might be cured." This statement is as true now as it was twenty years ago. By means of modern instantaneous radiography we are now enabled to discover deep-seated central tuberculous disease in the hilus and surrounding pulmonary tissue before tubercle bacilli appear in the sputum and long before physical signs manifest themselves.

The *prognosis* in the early stages is extremely good. Indeed, the earliest stage of hilus tuberculosis is one of the most curable of all morbid conditions, as is proved by the fact that the great majority of all lungs exhibit post-mortem evidence of healed tuberculosis in the root area, whether in the form of calcareous deposit or fibrous thickening. In the case of the hilus tuberculosis not strictly confined to the root area, but extending into the immediately surrounding pulmonary tissue—the peri-hilus—the prognosis is also very favourable if the patient's environment is a suitable one. It is only when the disease has reached the apex or other portion of the periphery that the outlook becomes much less hopeful, as the apical lesion is but too often associated with advanced central disease of which it is but an extension. Generally speaking a good prognosis mainly depends upon three factors (*a*) the early diagnosis of the morbid lesion, (*b*) the degree of resistance of the individual, and (*c*) the nature of the patient's environment. The ubiquitous tubercle bacillus probably obtains lodgment in the pulmonary root area of each and all of us sooner or later, and yet in over 80 per cent. of individuals the natural resistive power of our tissues is sufficient to effect a permanent cure. That environment as well as heredity plays an important part is proved conclusively by the fact that pulmonary tuberculosis claims its victims mainly from the poorly fed, poorly clothed, and poorly housed members of the community. The fact that most of us have had at one time active tuberculous deposit now represented by calcified glands or fibrous thickening of the roots may in reality be an advantage in view of our having to live constantly in a microbic environment. A definite degree of immunity due to the presence of anti-bodies has thus been gradually established during childhood, and we are actually in a better condition as adults to resist any future invasion than if we had never contracted the disease at all. It is probable, indeed, that the gradual reduction of tuberculosis mortality in civilised countries is largely due to the fact that the population has become gradually immunised in this way. Such a theory will serve to explain the alarming increased mortality from pulmonary tuberculosis when the disease has become endemic among the native adult populations of Bengal, the West Indies, and elsewhere when the inhabitants have not thus become immunised.

With reference to treatment little need be said under this head, except to emphasise the importance of commencing treatment at the earliest possible stage of the disease. Successful treatment is thus intimately linked up with the question of early diagnosis.

Dr. Gee's aphorism that "therapeutics must begin before physical signs are developed, and if you wait for physical signs you wait too long," exactly sums up the situation.

It is the characteristic X-ray appearances in conjunction with a confirmatory positive tuberculin reaction to which we must trust in deciding when to commence treatment.

It is in these cases of early hilus tuberculosis that carefully administered tuberculin treatment achieves its most signal triumphs. The increasing thereby of the protective properties of the blood and tissues at this stage will serve in most cases to completely check further progress of the disease and pave the way to a permanent cure. This is particularly so in the case of glandular tuberculosis in children. This is the time for strengthening the resistive power of the organism, whether by hygienic methods or by specific tuberculin treatment, or better still, by both methods combined.

The universal recognition by the profession of the importance of hilus disease and its early diagnosis may inaugurate a new era in the treatment of pulmonary tuberculosis.

The late Dr. Louis Merck, whose death occurred last week, was head of what is probably the oldest established chemical factory in the world—namely, that of E. Merck, of Darmstadt. The business was founded in 1668 by Friedrich Johann Merck, and has since remained in the uninterrupted possession of the family. The firm was one of the earliest pioneers in the production of alkaloids, being the first to supply cocaine on a commercial scale. It also held the monopoly in the manufacture of santonin about thirty years ago.

THE NECESSITY FOR STATE ENDOWED HOSPITALS AND A STATE MEDICAL SERVICE. (*a*)

By J. C. M'WALTER, M.A., M.D., D.P.H., LL.B.

The voluntary hospital system is dead. It had an honourable career, and marvellous success. Our only complaint is that the good is the enemy of the best. If it had not been so good, a better system would have come into operation much sooner. Hospitals were originally lodging-houses for pilgrims and strangers, conducted by members of religious orders. Hospitality, not cure of disease, was the dominant idea of their promoters. At this period of the world's history nobody supposed that a sick person would be better off anywhere than in his own home. In this connection certain pilgrims who took ill on their journeys were kept in these hostels, and finally an infirmary became a necessary part of the institution. All the time the idea was essentially charitable, and the expenses of the good work were met by the alms of the faithful. In time of plague or other epidemic the hospitals were probably used as places of detention for persons who might be a danger to the community. It became the rule that if any member of the religious order was skilled in medicine, he should attend the patients. If no such person was available, the nearest physician might be called in to attend. This was the germ of the modern hospital. St. Bartholomew's and Bedlam, St. Thomas's and Bridewell, all were founded thus. In later years various pious donors left legacies to the hospitals, and boards of trustees were founded, but the paramount principle was one of charity and philanthropy.

These ideas are out of date. The State, while spending £14,000,000 a year on combating sickness, cannot allow the most important part of the work to be at the mercy of the pious donors to hospitals. A few beds in a healthy house, perhaps a nurse or two, and an occasional visit from a doctor, constituted the idea of an hospital treatment up to half a century ago. Now, all the resources of architecture are lavished on the buildings, these costing up to nearly a thousand pounds per bed. They must contain the most elaborate bacteriological, radiological, and pathological laboratories. Teaching, curing, research, must all be carried on by eminent experts within their walls. A modern hospital is, in fact, a scientific university, comprising the highest teaching in every branch of science, as well as the most modern application of art to the cure of disease. A few years ago, Dr. Jordan Lloyd tells us, 3 per cent. of the population of Birmingham were treated in hospitals. Now over 11 per cent. are so treated. It is calculated that about a million operations are performed in the hospitals of Great Britain and Ireland every year. Will anyone suggest that this work will become lessened for the future? Or will it be argued that it must be done gratuitously?

At the Health Congress held in Berlin last year we were shown over the new Virchow Hospital. It cost practically a million of money, to say nothing of a yearly cost of £67,000. It spread over 67 acres, and held nearly 2,000 beds. The number of doctors attached was 157, and of employees about 1,100. This really is the type to which all modern efforts in hospital providing must approach. There is also in Berlin another hospital—The Charité—which is largely of a modern character, and is kept up by private donations. This serves for clinical teaching, which, we were told, is not permitted in the Municipal Hospital. The Berlin system seems to be one which might easily be adopted by British municipalities—at least, with an easy amendment of our Public Health Acts. It is estimated that the cost of each bed is three shillings per day, and for every patient three shillings must be found somewhere. Either the patient pays himself, or his insurance society pays for him, or the province from which he comes pays, or, in the last resort, if he be utterly helpless, the poor relief organisation pays for him. Now every sanitary authority can erect, endow, or maintain all hospitals with necessary equipment for infectious diseases. By an easy extension of this Act they might erect and endow hospitals for all diseases, or they might make bargains with the directors of such hospitals for the upkeep of patients. A defect of the Berlin system is that where the municipal authorities erect an hospital it is frequently unavailable for clinical teaching. It may, moreover, be limited in its freedom of medical research by the prejudices of the uninstructed community. If the hospital be not available for the training of students and practitioners, for medical research, and for the training of nurses, its utility to the community is greatly diminished.

There seems little doubt that insurance societies will for the future insist on patients getting hospital treatment as much as possible with a view to taking them off the benefit list. In such cases the society must be made to pay a fair proportion of the hospital expenses. The problem, then, is this. Obviously the State must contribute to the upkeep of hospitals; but in every city there are admirable hospitals superintended by boards of trustees in whom the public have often more confidence—and who are, perhaps, better served by their officers—than any merely State institutions. These would refuse to be wiped out by Act of Parliament, and to do so would be costly and unpopular. Clearly, the better plan is to let the State hand over to the trustees of a hospital a certain sum per day for every patient occupying a bed. By the State I mean also the local sanitary authority. A certain amount of control, a certain minimum standard of service and efficiency would, of course, be insisted on, but the financial burthen of the hospitals would be greatly lessened. The sum would probably be between three and four shillings a day. This would not represent the entire burthen of the patient, for the people are entitled to the benefit of whatever endowments a hospital has already.

Modern discoveries for the treatment of disease—light cures, electric cures, mechanical apparatus, diagnostic methods, vaccines, serotherapy, and the services of specialists in every department of medicine would then be available, not as a charity, but as a right, to the sick citizens. If each bed were paid for, whether by the sanitary authority or the insurance societies, then an insured person would be offered, in return for his weekly contribution, not merely the perfunctory services of the panel doctor, but all the array of a modern scientific hospital and its equipment, to cure his disease. That the State must endow hospitals, directly or indirectly, will not surely be denied, but the arguments for a State medical service are not so conclusive. We have now 14,000,000 persons receiving medical benefits under the Insurance Act. What does this mean? Simply that each person is on the "panel" of some doctor whom he happens to like. He treats his patients exactly as he chooses—it depends on his honour, or his humanity, or on his sense of what is profitable. He has no superiors and no criterion. He is welcome to treat the patient as indifferently as he fancies—provided he

---

(*a*) A Paper read before the International Congress of Medicine, London, August, 1913.

can escape actual censure for grievous wrong doing. If he has the patient's confidence he can do as he wishes; nothing can touch him. This, at least, has its advantages—it somehow fits in with British ideas of freedom of contract, but obviously it cannot last. We cannot continue to have fourteen millions of persons treated, as it were, by the privates of the profession, and at their sweet will. It would be as though all the hospitals in the three kingdoms were at the tender mercies of the house surgeons alone, with never a consulting surgeon or physician to come near the place. Specialism is the order of the day—it makes for excellence, and there is no proper provision for specialists in the existing condition of affairs.

It is unthinkable that the present ill-organised crowd of 14,000 doctors, without hierarchical organisation, who at present administer the Insurance Act can be allowed to continue their labours without being digested into a more uniform organism. The State simply must create a special service. There must be organisation, control, hierarchical order. The obvious scheme would seem to be one founded on the Army Medical Service model—that is, entrance by competitive examination—various grades of control and command, repeated examinations, as tests of efficiency and for promotion. Individuals need not be crushed out by a State medical service—the healing science has always charms as well as rewards for earnest effort.

The recent amalgamation of St. George's and Westminster Hospitals, and the sale of the ground on which St. George's stands, for the colossal sum of £480,000, shows what staggering sums are locked up in certain old-fashioned bodies of trustees. The State could, perhaps, in the course of time, institute an investigation into the financial conditions of many of such institutions and ascertain whether more good could not be done by amalgamation, sale of previous sites, better treatment of the hospital staffs, limitation of the number of posts, and other points.

RELATIONS OF ANÆMIA TO ACHYLIA AND GASTRITIS CHRONICA. (a)

By PROFESSOR KNUD FABER.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

FENWICK has first shown, in his well-known work of 1880, that in pernicious anæmia we find a complete achylia gastrica with anatomical changes in the gastric mucosa, and especially inflammation and atrophy of the glands. Later on, this state of things has been ascertained over and over again. It may be laid down as a fact that in all cases of pernicious anæmia an achylia is constantly found. The two or three cases in which the gastric secretion was still maintained did not conform to type with regard to the proportion of hæmoglobin to red corpuscles and the course of the disease.

To begin with, the gastric disease was looked upon as being the cause of the anæmia; thus William Osler in 1886 and Kinnicut in 1887; but little by little another opinion has prevailed. The achylia is sometimes regarded as the sequel of pernicious anæmia, or more often the achylia and anæmia are regarded as two concomitant phenomena due to the same cause, which is thought to be either a general toxic poisoning or an infection. Especially Hunter is known to hold the latter view.

If, however, we look into Osler's and Kinnicut's observations we find that symptoms of gastritis appeared long before the appearance of anæmia; and in Osler's case the ætiology of the gastritis was quite clear, the gastritis being due to alcoholism. Later observations, too, have shown that the presence of the symptoms of gastritis a rather long time before those of anæmia is a frequent occurrence. These observations, however, are not conclusive, as a concurrent examination of the gastric secretion and the blood at this early stage is wanting. I have been so fortunate as to have had under my observation three cases of pernicious anæmia in which a complete and chronic achylia had manifested itself several years before any anæmia whatever existed in the patient. Indeed, 3, 8 and 10 years respectively before the appearance of the typical and fatal pernicious anæmia, a normal quantity of hæmoglobin and a complete achylia were shown in these three patients.

CASE 1.—Man of business, æt. 30.

In 1903, achylia found for the first time and also symptoms of glossitis. In 1907 and 1908, achylia found again and normal quantity of hæmoglobin. In 1911, typical pernicious anæmia with hæmoglobin 22 per cent. and 840,000 red corpuscles (index 1, 3). Death.

CASE 2.—Solicitor, æt. 55.

In 1909, achylia and hæmoglobin 100 per cent.; 1910 and 1911, same condition. In 1912, typical pernicious anæmia; hæmoglobin 30 per cent.; red corpuscles, 1,000,000 (index 1, 5). Death.

CASE 3.—Man of business, æt. 54.

In 1902, achylia; hæmoglobin 95 per cent. In 1910, still achylia, light anæmia (60 per cent.). In 1912, typical pernicious anæmia; hæmoglobin 30 per cent.; red corpuscles 900,000. Death, 1913.

Considering that no case was ever seen of achylia developing secondarily during the progress of pernicious anæmia, and comparing the above cases with the observations of Osler, Kinnicut, and others, it may be laid down as a fact that the chronic gastritis with achylia was present primarily, and that pernicious anæmia appeared as a sequel, or rather, perhaps, as a complication of the former. This opinion is further supported by the fact that in patients suffering from chronic achylia there will often appear anæmia of a lower degree and a more benign type, so that pernicious anæmia is out of the question.

By examining a rather large number of in-patients from this point of view, very illustrative results are arrived at.

Thus I can give information about 207 cases of chronic achylia treated at the University's Hospital of Copenhagen. Of these, 22 were suffering from pernicious anæmia, and no less than 37 showed lighter anæmia having a percentage of hæmoglobin from 80 to 50 and below. Fifteen of these showed a percentage of hæmoglobin below 50, and yet pernicious anæmia was quite out of the question, the red corpuscles having sunk only to from three to four millions, which placed the colour index considerably below one, a condition the very reverse of that found in pernicious anæmia. Furthermore, these cases of anæmia did not tend towards progression, though not towards curing either. In spite of proper treatment one may see them keep their anæmia rather unchanged through years. Some of them I have followed for seven years, always finding a percentage of hæmoglobin of from 40 to 60 and about 400,000 red corpuscles. Most of all they resemble pertinacious chloroses, but are specially characterised by the constant presence of achylia accompanied by its frequent diarrhœa and dyspeptic symptoms. As is the case with pernicious anæmia, chronic achylia should, in these cases of lighter anæmia, be looked upon as the primary lesion.

(a) Paper read before the Section of Medicine International Congress of Medicine, London, 1913.

The cause of the chronic achylia is a chronic gastritis. Formerly too much stress was laid on the atrophy of the mucosa so frequently met with in this gastritis. The atrophy should only be regarded as a final result of the gastritis. The more prolonged the gastritis and the achylia the more pronounced the atrophy. If the patient for years has shown symptoms of gastritis and then gets a pernicious anæmia the *post-mortem* examination will show extensive atrophy, but if the anæmia kills the patient before the gastritis has existed for a long time, say a year or so, the mucous membrane will show extensive inflammatory processes, but no atrophy. The peptic glands are well preserved, but they have ceased their functions; there is complete achylia without atrophy. As Lubarsch, we might designate the disease as a *gastritis progressiva atrophicans.*

Thus it is not the anatomical changes themselves we have to look to for the cause of the anæmia, nor to anatomical changes of the intestinal tube, which is found to be quite normal in spite of a pronounced pernicious anæmia. It is also difficult to attach any direct importance to the glossitis of Hunter. Glossitis with pains, tenderness, and redness of tongue occurs very early in achylia, but it seems mostly to be a phenomenon concomitant with the gastritis, for in one of my patients it was found clearly defined along with the achylia nearly eight years before the patient got his pernicious anæmia of which he died.

The most likely ætiology at this moment seems to be the one that seeks the origin of anæmias in the chronic achylia itself, which supplies the soil in which the anæmia develops. It is of special importance that in case of achylia the stomach loses its power of disinfecting its contents. Duodenum is sterile no longer, and quite an abnormal and luxuriant flora develops in the intestinal tube. Maybe, an infection is thus caused; maybe, there is only a development of hæmolysins of bacterial origin in the intestinal tube itself. By their absorption into the blood the hæmolysis arises which is so decidedly present, especially in pernicious anæmia, and to which Hunter so early called our attention.

THE MEDICAL TREATMENT OF PILES.

By CH. DUBA, M.D.,
Of the Faculty of Medicine of Paris.

[Specially Reported for this Journal.]

I have treated upwards of three hundred cases of piles with very great success on the lines which I propose to describe. This treatment may conveniently be divided into—(1) internal; (2) external; and (3) general.

Internal treatment.—During the stage of acute inflammation the patient is to be given, daily, for three days:—

Linseed tea (10 per cent.), 2 pints.
Glycerine, dr. vj.

This is taken in wineglassfuls, and on the second day some relief will already be experienced. If the state of the kidneys allows of it, we then order him:

Salicylate of soda, gr. viij.
Bicarbonate of soda, gr. viij.
Exalgine, gr. iss.

in one cachet. One to be taken before each meal.

If, after taking twenty of these cachets in conjunction with the general and external treatment, recovery has not taken place, we must go back to the linseed tea for three days, then resuming the cachets. I have very rarely found it necessary to repeat the internal treatment. As a rule, at the end of three weeks I discontinue the internal treatment, merely continuing the external treatment until the disappearance of the hæmorrhoids.

External treatment.—Every day two sitz baths at 102° F., containing a pound of sodium chloride. To remain in for half an hour. A pint enema of decoction of marsh-mallow—if this can be given; if not, apply five or six leeches round about the hæmorrhoidal swelling. After the enema or the leeches, paint with:—

Hydrochloride of cocaine, gr. viij.
Extract of belladonna, gr. xv.
Extract of hyoscyamus, gr. xx.
Glycerine, dr. iv.
Misce. Fiat pigment.

Cover with a moist dressing which, in its turn, is covered with protective. After three days, when the inflammation has subsided, apply the following lotion:—

Calomel, gr. lxxx.
Solution of adrenaline (1 per cent.), dr. iiss.
Lime water, fl. oz. v.
Ft. lotio.

Steep a pad of lint in this solution, and apply for from three to five minutes to the piles previously smeared with the glycerine preparation, to be repeated every morning. Then powder with the following, every evening:

Oxide of zinc, oz. iss.
Powdered opium, gr. lxxx.
Naphthol B., dr. iiss.
Misce. Signe "The Powder."

Every morning, after applying the lotion, cover the piles with a moist dressing and a piece of protective. Although the morning lotion and evening powder may appear to be rather caustic in spite of the previous application of glycerine, not one of my three hundred patients ever declined to go on with the treatment on account of pain; indeed, several assured me that the pain, such as it was, did not amount to anything, and seemed to relieve the suffering caused by the piles.

Dietetic and hygienic treatment.—(a) Three days' strict milk diet; ten days' lacto-vegetarian diet, then ordinary regimen. (b) Complete rest on the back with the feet raised. After a time the patient may be allowed to lie in whatever position he pleases, and lastly, he may take a little exercise. With an obedient patient it is rarely necessary to forbid exercise after the thirteenth day, by which time all inflammation will have subsided. By means of this simple treatment, for it is simple enough although as described it may seem complicated, I have been able to spare my patients many an operation. Here are notes of two or three of the cases thus treated.

Cases.—A man, age 45, weaver, complained of severe anal pain for three weeks. He lost blood, but there was no pus. Loss of appetite, insomnia and rapid wasting, yellowish complexion. His doctor suspected cancer. I found a large, violet, smooth, oozing mass obstructing the anus, rendering rectal examination impossible. For the past twenty years he had had slight bleeding from the anus every ten or fifteen days. He was anxious to be operated, but I suggested that he should give this treatment a trial before deciding. The treatment was applied in its entirety except that no enemas or leeches were employed, and in three days there was marked improvement. After ten days the patient wanted to return to work. In five weeks recovery was complete. Between 1897 and 1904 this patient had no return of his piles.

A paralytic, 72 years of age, had itching and pain in the anus, which prevented sleep and caused discomfort when sitting. He was very depressed. He had been suffering thus for six years. Round about the anus were six small reducible swellings, which oozed a good deal. He had myocarditis and arrhythmia, slight hypertrophy of the liver, albuminuria and obstinate constipation. He underwent the treatment except that, in view of the state of his kidneys, rhubarb and bicarbonate of soda were substituted for the salicylate of soda, and the enemata were also dispensed with. Recovery was brought about in six weeks, and he never suffered from piles any more down to the date of his death.

A clerk, æt. 26, had been suffering from attacks of bleeding every two or three days for six weeks, and the repeated loss made him so weak that he was constrained to keep his bed. He was markedly anæmic. He had had anal pain ever since he was 18 years of age, and this was accompanied by attacks of muco-membranous colitis. Round the anus were several irreducible tumours, effectually preventing movement of any kind. The entire treatment was applied, with immediate relief. He was able to leave his room on the tenth day, and three weeks later the piles came away. It is now twelve years since he was treated, and there has been no return.

I venture to suggest that whenever the practitioner is dealing with a case of hæmorrhoids for which surgical operation appears indispensable, a trial should be given to this treatment, which will often, if not always, dispense with the necessity for bloodshed. Moreover, operations on the rectum expose the victim to certain disagreeable sequelæ, especially when the operation is done by comparatively inexperienced persons, and in private practice where hospital facilities are not available.

OPERATING THEATRES.

LONDON TEMPERANCE HOSPITAL.

Operation for Tuberculous Pyosalpinx and Dermoid Ovarian Cyst.—Mr. Herbert Paterson operated on a woman, æt. 37, who had had a sinus discharging pus from the pelvis for over three years. In March, 1910, the patient had had an attack of "peritonitis," accompanied by vomiting and acute pain in the lower abdomen. The attack lasted five weeks, during which time she had a slightly raised temperature. She was admitted into the hospital in July, 1910. The patient was very ill, having a temperature ranging between 98° and 103° F., and there was a fixed, round, hard swelling in the hypogastric and right iliac regions. A diagnosis of tuberculous pyosalpinx was made, but it was decided to wait and see if the temperature would settle down before an operation was performed. Under rest in bed and open-air treatment the patient's condition slowly improved, and at the end of August the abdomen was opened. After separating much matted intestine, a swelling, about the size of an orange, was found on the right side of the uterus, apparently connected with the right tube. Removal of the swelling was impossible, so it was opened, allowing the escape of much offensive pus; a drainage tube was tied into the abscess cavity and brought out at the lower angle of the wound. Patient was very ill after the operation, but eventually made a good recovery and left hospital with a sinus leading into the pelvic cavity.

After leaving hospital the sinus continued to discharge pus, and the patient was treated with tuberculin injections. A year later the patient was readmitted, and an attempt was made to induce the sinus to close by making an opening into the lower end of the sinus from the vagina. Later, several attempts were made by scraping the sinus and by treatment with a vaccine, but without success. As the discharge of pus caused the patient a lot of annoyance, she was admitted again for further treatment. An incision was made in the abdomen above the sinus. On opening the peritoneal cavity it was found that the small intestine was adherent to the abominal wall round the sinus. An encircling incision was made round the sinus, clear of the adherent intestine. Mr. Paterson then carefully separated the intestine from the abdominal wall. The walls of the sinus were found to be formed entirely of adherent intestine. This intestine was carefully separated from off the sinus and was found to extend right down to the rectum. A portion of the right tube was removed, and the cyst which was found on the left side of the abdomen was also removed, together with a portion of the tube on that side. The peritoneal and muscular coats of the rectum were torn and sewn up. The separated portions of the intestine which had formed the walls of the sinus were much thickened. They were swabbed with Harrington's solution and absolute alcohol. A tube was placed in Douglas's pouch, the wound being sewn up in three layers, thread for peritoneum and fascia, silkworm gut (subcuticular continuous suture) being used for the skin. Three interrupted silkwork gut sutures were placed at intervals, being tied over a strip of gauze dressing. The cyst removed proved to be a dermoid, containing a well-formed tooth.

Mr. Paterson pointed out that the opening up of sinuses such as this, the walls of which were formed entirely of intestine, was a serious operation, and should be undertaken only after a very prolonged and thorough trial of less severe measures. In this case many attempts had been made during the previous three years to secure healing of the sinus, and it was only at the patient's urgent request, because the offensive discharge from the sinus prevented her from earning her livelihood, that the operation was undertaken. The operation findings showed that there was little prospect of a cure being obtained without operation. The tubes were extensively diseased, and the thickened abscess walls left from the previous operation showed little signs of healing. The chief danger in such cases was the risk of damaging the small intestine in separating it from round the sinus. Fortunately in this case no untoward results ensued.

The sinus continued to discharge a considerable amount of pus, and at times the patient's temperature rose to 100° F., but after the sinus had been filled up twice with bismuth paste it healed up, and the patient left hospital after a stay of about six weeks.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, September 27th, 1913.

At the Gesellschaft für Psychiatrie und Nervenkrankheiten, Hr. Forster showed

Spirochætes from Cerebral Puncture Fluid of Paralytics.

The spirochætes were obtained from two cases of paralysis. In both preparations which were stained by the Fontane-Tribondeau method the typical germs were found. The speaker had now examined the cerebral puncture fluid of 16 cases of the disease. In four of them, in the dark field living spirochætes could be seen. In the last case but one masses of the germs were seen perhaps as many as would be met with in a primary sore; in the last case of all they were numerous, but there were not so many living forms. The dark field preparations were dried and stained and were the ones shown. The first case in which the speaker had demonstrated living spirochætes was now dead. The *post-mortem* examination showed the case to be one of typical progressive paralysis. No signs of cerebral syphilis were to be seen at the examination. A number of spirochætes were found, however, in a smear preparation made immediately after the *post-mortem* examination had been made.

The examinations showed that the spirochætes were really present, and that what was seen was not nerve fibrils stained by silver. The cerebral punctures were not made for the purpose of ascertaining whether spirochætes were there, but for the purpose of inoculation in order to determine whether the fluid was still capable of causing infection, and to determine whether the paralysis was due to some special form of spirochæte.

No spirochætes had hitherto been found in the ventricular or lumbar fluid of such cases, not even in the one that yielded such abundance in the cortex.

Hr. Henneberg remarked that it was possible that spirochætes might be found in non-paralytic cases of old-standing syphilis. It would be interesting to learn the condition of the brain in such cases, *i.e.*, as regarded the presence of spirochætes.

Hr. Bonhoeffer said that puncture of the brain of paralytics could not be recommended for diagnostic purposes, but it was done in the speaker's cases in order to ascertain whether living and infective spirochætes were present.

Hr. Kramer showed a case of

Friedreich's Disease with Myosthenic Reaction.

The patient was a youth, æt. 18, with no hereditary taint. When 7 or 8 years old, contraction of the fingers of the left hand began, and a year later those of the right hand. Gradual curving of spine followed. Three years ago the speech changed and the gait became uncertain. The pupils reacted and there was no nystagmus. The speech became monotonous and scanning. There was no other evidence of cerebral disease. The fingers of both hands had the claw position. The inter-ossei were not atrophic, they reacted normally to electric stimuli. Ataxy of the arms, kyphoscoliosis. Wide ataxic gait. Ataxy of the legs in the supine position. Patellar and Achilles tendon reflexes absent. Bilateral Babinski's sign. The skin reflexes and sensibility were normal. There was a more or less pronounced myasthenic reaction in all the muscles to the Faradic current both direct and indirect. No tiredness to be determined by the galvanic current nor was there any from voluntary movement. The most pronounced was the myasthenic reaction in the region of the peroneus. With prolonged Faradic stimulation a powerful tetanic condition was brought about. After a short time this ceased and gave place to one of moderate individual contractions; after a few minutes the muscle was quite exhausted and only occasionally showed a few individual twitchings. Interruption of the current even for a few seconds restored the tone mostly, but the contractions were less strong and more easily exhausted than before.

Hr. Schuster believed that the contractions of the fingers noticed were due not to any change in the joints or of the muscles, but to a contraction of the soft parts of the finger on the side for flexion such as was seen so commonly and especially in certain families. He had observed that there was a nervous peculiarity in families that showed the contracted fingers, and he would ask Hr. Kramer if other members of the family in his case showed anything similar. As regarded the hollow foot of Friedreich's disease, it had been pointed out that spina bifida was frequently associated wth the condition. For that reason he had all his cases of suspicious foot formation Röntgenised—that was, he had had the pelvis Röntgenised. He had come to the conclusion that not only was there a connection between the two, but that that connection was a causal one, and that the condition was due to some injury to the cauda equina or some lower part of the spinal cord.

Hr. Kramer, in reply, said that the hollow foot could only depend on loss of muscular power, but, at the same time, it was curious that the case he had just shown was also one of spina bifida.

AUSTRIA.

Vienna, Sept. 27th, 1913.

Treatment of the Fatty Disease.

The views regarding the ætiology and treatment of morbid adiposity have just been discussed by Dr. S. Hay, of Vienna. The fact was, of course, familiar to the old practitioners that there was a special tendency in some individuals to the accumulation of fat, and under conditions which in ordinary persons led to no such result. Cohnheim was the first to lay stress on the probable diminution of the functional oxidising power of the organism—at least in case of fats; and that defect was analogous to that present in diabetes regarding carbohydrates. But the most modern physiological exponents of metabolism, such as Von Noorden (Vienna) and Umber (Charlottenburg) are recognised to be, have adopted a completely opposite viewpoint. Indeed, Von Noorden states that he knows of no individuals or classes of the community who possess any congenital tendency to the morbid deposition of fat; his view of the ætiology of the condition being represented by excessive nutrition associated with insufficient movements. The fact that the members of the female sex in general show a much greater disposition to adiposity is regarded by him as the result of their greater liking for soft foods and their undeniably greater indulgence in rest, etc. The view of many authors that the sexual processes have also an influence cannot be wholly rejected, in presence of the fact that women often accumulate much fat during the enforced stillness of pregnancy, more especially during the latter portion of the term, when nutrition is so luxuriously provided and with so anxious care; and the subsequent lactation, when fluid nutriment is so copiously administered. The fatty accumulation which tends to follow the climacteric corresponds pretty closely to the increased fatty deposit in men after the age of 40.

Dr. Hay is so far inclined to agree with Von Noorden's theory, as the result of his researches tends to show that in every individual case of excessive fatty deposit there has been excessive administration of nutriment, liberal use of alcohol, insufficient bodily movements, or unnecessary prolongation of sleep—in short, that in each individual case the administration of nutriment was out of proportion to the bodily movements. Accordingly, he believes that this rule of due proportion between food and exercise must always be our foremost consideration in the management of the fatty disease. He passes in review the principal modes of treatment that have been recommended; and, while admitting the merits of some of the individual items, insists that lowering of the diet must always remain the chief factor. He dismisses the bleeding, salivation, and sweating procedures formerly so much in fashion, and proceeds at once to the examination of respective merits of the medications most strongly recommended. Foremost among these he places the thyroid preparations. These have an unquestionable oxidising influence on fat; but their effect on the albumin of the organism is by no means so beneficial, as is often seen in resulting faintness, palpitations, etc. Erythema is another of the inconveniences, and systemic intoxications are found to result in many cases. Thus great caution and foresight must be used in regard to the nervous and circulatory apparatus, especially when adopting this form of organo-therapy. And not less important is it to bear in mind, too, that in many cases after administration of thyroid preparations to fatty subjects, not only has glycosuria appeared, but diabetes has even been permanently established. Preparations of iodine, and especially iodide of iron, have been recommended. Salomon has made a special preparation, of which the principal constituent is the extract of fucus vesiculosus (bladder-wrack, 0.4 g. in each pastille), to which extract of tamarindus indica and of cascara sagrada have been added. But as symptoms have followed its use rather like those following the thyroid preparations, it cannot be regarded as a wholly harmless remedy. Danel has recommended scammony as a specific. Baths, when employed with due precautions, make a valuable adjuvant.

HUNGARY.

Budapest, Sept. 27th, 1913.

POTTS' DISEASE IN CHILDREN.

FROM an extensive study of the disease, as well as considerable experence in dealing with same, Aufricht draws the following conclusions (1) Tuberculous spondylitis is pre-eminently a disease of the young child. (2) The greatest number of cases is found between the ages of two and eight years. (3) In his hospital experience Dr. Aufricht met a greater number of boys than girls. (4) The duration of the disease before admission to the hospital was between a few weeks and nine months. (5) In the presence of undoubted predisposition, whether because of heredity or on account of surrounding conditions of life, measles, and at times trauma, may serve as the starting point of the disease. The complication of spondylitis by measles shows itself very rapidly in deterioration of the patient's condition. (6) The lumps were mostly found in the thoracic portion of the spine; the lower thoracic vertebræ were usually the most affected, and the curvature was generally limited either to these vertebræ or to the upper lumbar. (7) With the evacuation of the abscesses followed by filling up of the cavities with a 10 per cent. solution of idoform emulsion. or after a curettage done with the same aim in view followed by a hermetic closure of the opened abscess, satisfactory improvement would be observed in those localities where the skin has not grown thin. (8) Cases of active surgical interference and further treatment with drainage also showed a considerable degree of improvement, though the most frequent post-operative complication was usually a febrile condition. (9) Correct methodical extension and counterextension in bed often, in combination with suspension with the Sayre apparatus, is to be considered as the best means in the majority of cases, of checking development of the tuberculous process and of creating favourable conditions for the further treatment with corsets. (10) Besides the specific treatment it is absolutely necessary that resort be had to favourable climatic surroundings, as in special sanatoria at the shore of the Adriatic, or on the mountains, but never at a hospital. (11) Out of six who died four were found to have suffered from pulmonary tuberculosis, and two had in addition fatty degeneration of the heart.

THE TRANSMISSIBILITY OF TABES.

There are scant data concerned with the fecundity of tabetics, according to Dr. Haber (*Orvosko Lapja* 1913, August 21st). It appears that their procreative power is diminished, the proportion of childless households among tabetics being very large. Since the same is true of syphilitics it is possible that such sterility may be the result of syphilis rather than of tabes. The same observation may apply to the great mortality of the children of tabetics. Most of the cases published of hereditary tabes are usually of Friedreich's ataxia. There are undoubtedly cases of hereditary tabes, but their number is so small as to be negligible. The small proportion of cases of juvenile tabes, the issue of tabetic parents, when compared to the larger number of cases the issue of syphilitic parents, suggests that hereditary syphilis is the direct cause of juvenile tabes. A large proportion of the offspring of individuals affected with locomotor ataxia are affected with nervous disorders. Tabes cannot be blamed as being the cause of these, for heredo-syphilis creates the same predispositions and nervous accidents. Moreover, in tabetic households children born before the parent, or parents, have contracted syphilis and tabes have the same tendency to nervous diseases.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

THE particular question which has most recently been agitating the medical mind is that of post-graduate medical teaching. For a good many years the staff of the Royal Infirmary have provided in parts of the off-seasons of undergraduate teaching a series of short post-graduate courses of lectures. More recently the Western Infirmary staff have advertised and have held such a series. The present arrangements do not seem to suit the convenience of the bulk of medical practitioners desirous of benefiting by the teaching, and an agitation has commenced with a view to bringing all post-graduate teaching under one control, and arranging it so that, as far as possible, every practitioner may, if he choses, take advantage of the teaching to its fullest extent. It has been suggested that the University should be the central and controlling authority; but another opinion is that the University has neglected the matter in the past and should not be asked to intervene. There seems to be an opening for the staffs of the various hospitals to unite in appointing a joint board to make suitable and harmonius arrangements.

The dispute as to the adoption or non-adoption by the Scottish Universities of an inclusive fee in medicine has been in abeyance during the holiday season, but will no doubt break out again with renewed vigour upon the opening of the winter session, unless those who have been pressing the movement forward should desist from their endeavours. A joint meeting of the staffs of the Glasgow extra-mural schools and a meeting of the Royal Faculty of Physicians and Surgeons of Glasgow have unanimously condemned the proposal for an inclusive fee. Two of the extra-mural schools are hampered in their action by being dominated, in their governing bodies, by laymen: a disadvantage which is not shared by the third, as it is constituted on the lines of the School of Medicine of the Royal Colleges of Edinburgh. But for this disadvantage, the two schools referred to, as well as the third, would no doubt have long ere this pronounced an emphatic opinion against the proposed inclusive fee as inimical to the extra-mural schools, as Edinburgh School of Medicine has done.

On October 31st, 1910, Mr. William Robertson made a gift to Victoria Infirmary of £5.000, for the purpose of providing it with a clinical research laboratory, and this laboratory, being now ready, will be opened by Lord Rowallan, the Chairman of the Governors, on October 2nd This important addition to its equipment will put the Infirmary, in this respect, on a par with the best hospitals, with which it will now be in line.

The late Dr. James Provan, who was L.R.C.S.Edin. and M.D. of Glasgow University, was a well-known practitioner in what is now the Govan district of Glasgow. He died at his residence in Ibrox on the 23rd inst. Dr. Provan was a Surgeon-Colonel in the volunteer section of the Royal Garrison Artillery when he retired from that force about ten years ago. He was well known as a collector of pictures and curios. His licence and his degree were both taken as far back as 1864.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents]

MEDICAL MEN AS DENTISTS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your correspondent, Dr. Keogh, is quite right; there is no legal bar to the practice of dentistry, and the assumption of the title "dental surgeon" or "surgeon dentist" by any qualified medical man. Although there seemed little need for it, a clause making this point clear was inserted in the Dentists Act. There could be no reason why a surgeon should not practise dentistry when allowed to practise aural or ophthalmic surgery, for example. But there is a very cogent reason why a medical practitioner cannot act as a dentist. Dentistry is a mechanical handicraft calling for a high degree of technical skill only to be gained by those who have more or less of the gift of fingers, and who have undergone the necessary training. A six months' course of instruction in dentistry may make a man a fairly good "extractor" in simple cases, and may enable him to put in a simple dressing in an aching carious cavity. But if he wants to practise as a dentist with comfort to himself, and with a chance of success, he will need at least the amount of training demanded from candidates for the L.D.S. He will need at least two years' training at the mechanical work-bench; he will need at least two years' training in a dental hospital. These years can be, of course, concurrent. A candidate for dentistry is well advised when he gives himself a few months of probation at the work-bench. If at the end of that time he feels that he has the taste and talent for the craft he can go on, otherwise he can retire in time. It does not matter how learned and scientific as a surgeon he may be, a man cannot honestly set up as a dentist without real qualifications for the speciality. Besides the operations of conservative dentistry, there are a vast variety of prosthetic operations called for, such as "crowning" and "bar and bridge work," not to speak of the construction and fitting of artificial teeth. Unless a practitioner is prepared to do all these kinds of work he cannot succeed or even practise as a dentist. Dentistry provides a capital field for quackery, and for the operations of unscrupulous mechanics of a certain class. The Dentists Act is powerless to prevent these men from practising and assuming titles. Through their ignorance they are inflicting an incalculable amount of injury and suffering upon the simple public. This was all once more explained in a recent issue of the *Nineteenth Century* by Professor Arthur Underwood. The dearth of qualified men is, to a large extent, explained by the existence of the dental quack. We may expect legislation to deal with this some time within the next thousand years.

I am, Sir, yours truly,
September 26th. Hospital Dentist.

FRENCH DRAINS AND MALODOROUS FRANCE.

To the Editor of The Medical Press and Circular.

Sir,—The correspondence which your editorial paragraphs of August 3rd, under the above heading, has brought out, has been interesting and important, but some of the writers have missed the main point. The question of the sanitation of French hotels frequented by tourists is of very minor importance. What concerns those who, like myself, are bound to France by feelings of affection, and who have, besides, vital interests involved in questions of her prosperity; what concerns all Frenchmen imbued with true patriotism is the fact that in consequence of the incredibly backward state of public hygiene, the French death-rate is far higher than that of Great Britain, or Germany or any of her northern neighbours. All the facts were, as before pointed out, laid bare at the Paris Hygienic Congress in May last, and were emphasised in speeches by leading men, including two ex-Premiers, Ribot, and Bourgeois. Paris, "the city of light, which illuminates the whole world with its intellectual and scientific beams," is one of the most unhealthy capitals in Western Europe. It displays a mortality in tuberculosis and typhoid fever two and three times comparatively as great as that of Berlin and London respectively. And it must not be forgotten that the population of France, owing to the low birth-rate, would be diminishing were it not for the gradual nationalisation of the 1,500,000 foreigners domiciled on her soil. In view of the menace from German numbers alone, France has been obliged to impose a three years' military service on the whole of her manhood. This almost intolerable burden leaves her still with a more than dangerous numerical inferiority, and this disparity will increase from year to year.

The German birth-rate begins to fall, but her death-rate is comparatively low and falling. From 50 to 100 years will be needed to bring her to a position similar to that of France. These are the facts that pre-occupy French statesmen. The insanitary state of France, as I and my friend, "M. B. J.," have tried to show, is inflicting directly and indirectly enormous injury upon French trade and commerce. One of the best ways to overcome apathy is to address the argument to the pocket. The French are keen business people, and I have suggested that if the various British Chambers of Commerce in Paris and elsewhere could be induced to take up this question, and bring it to the front, they might compel the Press, which now ignores it, to give it the attention it deserves, and might start a movement towards the radical and great reforms which every lover of France who is aware of the present conditions must ardently long for. Thanking you for the courtesy you have shown in giving me so generously of your valuable space.

I am, Sir, yours truly,
Anglo-Francais.
Hotel Metropole, Northumberland Avenue,
September 25th, 1913.

MR. SHERREN'S LECTURE ON "THE DIAGNOSIS OF CHRONIC ULCERS OF THE STOMACH."

To the Editor of The Medical Press and Circular.

Sir,—Mr. Sherren needs no praise from me, and it is not at all astonishing to note the super-excellence of lectures emanating from that now famous school of surgery and wide field for clinical observation, the London Hospital. My great appetite for medical literature of every superior sort would probably have led me to read Mr. Sherren's lecture, even if my eye had not been caught by the following from among the opening paragraphs:—

"In no department of surgery is diagnosis so difficult and treatment in the appropriate cases so satisfactory as that of digestive disorders, considered by the populace, and often by the profession, as 'indigestion.'

"I would impress upon you that indigestion, while a useful term to denote symptoms associated with the ingestion of food, is often a dangerous cloak to hide ignorance. We should never be content until we have arrived at a conclusion as to its cause, remembering that in many instances it is but a danger signal of disease in other organs. Large numbers of patients with cholelithiasis and chronic disease of the appendix are treated medically, labelled dyspepsia, often with disastrous results."

On these paragraphs I should like to make an observation, far as it lies from the actual practical issues discussed by Mr. Sherren.

In my pamphlet on "Quackery and Medical Law Reform," the following passages appear:—

"The mischief arising from quack nostrums of all sorts is well exemplified by the class of indigestion cures. Indigestion—pain or discomfort at some part of the alimentary canal—is merely a symptom, not a distinct disease. It very often indicates merely a functional disturbance due to temporary or continued errors of dietary; on the other hand, it may be a sign of organic or malignant disease.

Cases of the more serious kind are always to be found in hospitals, and inquiry usually discloses the fact that many of them have been dosing themselves with quack medicine until, their malady having assumed a serious or mortal phase, they have been compelled to seek relief in the wards. In late years I have given up systematically inquiring for such cases, but lately I casually came across a series whilst acting as visiting member of the committee of our local hospital. These were women suffering from ulcer of the stomach, a disease which begins usually with 'indigestion.' They had all been taking for prolonged periods one or other of the most largely advertised indigestion 'cures.' One of these is a pill composed solely of aloes and soap; another is a potion the constituents of which are treacle and water, with a little aloes and capsicum. The actual value of the contents of a shilling packet would be perhaps one farthing. One of the hospital cases to which I have referred ended fatally; the life might have been saved by early diagnosis and treatment."

The observation I wish to record is this: If hospital surgeons like Mr. Sherren would be kind enough to look out for and note authentically even a few of the cases which pass through their hands, such as I have described, they might accumulate a mass of evidence of immense value in promoting legislation against the quack medicine trade. The trade in fraudulent nostrums engages a vast amount of capital, it suborns great numbers of newspapers, and through this and other means has probably succeeded in throwing into the eyes of at least some members of the Parliamentary Select Committee enough dust to confuse and obscure their judgment. It seems more than probable that when that Committee shall have published its report it may be necessary to revive the agitation that led to its appointment. In every department of every hospital evidence of the kind needed is to be discovered; it would be good if their staffs could be induced to give to the subject the attention I plead for.

I am, Sir, yours truly,
Henry Sewill.

DRUGGED OR DRUNK—A POLICE DIAGNOSIS.

To the Editor of The Medical Press and Circular.

Sir,—Some days ago a policeman accosted a patient of mine in the street, and accused him of being drunk. Certainly the man was staggering and dizzy. He was delirious, lively, and irritative. He could scarcely see, his voice was strangely husky. His face was flushed and he was terribly thirsty. His pulse was quick.

As the late Judge Morris would say, the guilt of the accused was as plain as the nose on your face, and nobody but a fool or a juryman would doubt it.

But was the man really drunk? Not at all. He was a perfect crank of a teetotaller, but he had hæmorrhoids, for which I had prescribed suppositories containing zinc, bismuth, and 1½ grains of belladonna extract. He had used one of these the previous night.

The moral is——

I am, sir, yours truly,
J. C. McWalter.

Dublin,
September 18th, 1913.

OBITUARY.

DR. JAMES WILLIAMS, OF HOLYWELL.

We regret to record the death of Dr. James Williams, aged 88, which took place at Holywell on the 19th ult. The deceased, who qualified as M.R.C.S. in 1848, was probably the oldest medical practitioner in North Wales, was a native of the town, and the son of the late Mr. Peter Williams, surgeon. Dr. Williams was for 58 years one of the vaccination officers of the Holywell Union, and for 37 years Medical Officer of the Holywell Rural District Council, both of which appointments he resigned four years ago owing to advancing years.

Dr. Williams had played a prominent part in the public life of the district. He was Chairman of the old Local Board in 1872 and again in 1879, and he was the first Chairman, in 1895, of the newly formed Urban Council, continuing in the office during the following three years. He was an indefatigable worker for the welfare of his native town and a familiar figure among all classes during his long and active career. He leaves two sons and two daughters to mourn his loss. He was a Churchman and a Conservative.

SPECIAL REPORTS.

CROYDON MENTAL HOSPITAL. (*a*)

The report of the Croydon Mental Hospital gives one a fair idea of how a modern asylum is run. The accommodation is comparatively small—650 was the maximum in 1911, but we are glad to see that research into the ætiology of the various mental disorders is being made the subject of investigation. Heredity is found to be an important factor. An insane history was found in 55.4 per cent. of cases admitted during the year and a direct parental inheritance in 34 per cent. Of those lunatics who had an insane history only 28 per cent. recovered, against 46.2 per cent. of those whose history was clean. The Medical Superintendent realises what should be, but apparently is not, obvious, that lunacy is a branch of medicine, and recommends that a mental clinic be established at every country hospital to be presided over by the medical officers of the local asylum. His object is to get into early touch with mental cases, whose friends at present have an unreasoning horror of the name asylum. We hope that such clinics will be established. They exist already at Munich and Berne, and tentative efforts are being made at some of the large London hospitals on the lines indicated. Music and dancing are held in good therapeutic repute at Croydon, a practice supported by the testimony of Pythagoras, who used them in cases of "anger, malice, and all such disorders of the mind" "against the dejections and corrodings of the same."

MEDICINE IN THE CANAL ZONE. (*b*)

These volumes are chiefly notable as evidence of the wonderfully complete manner in which the United States Government has attacked the problem of making the Panama Canal Zone into a habitable region. As side branches of the sanitary scheme without which the engineers' work would have been handicapped past tolerance, if not brought to nothing, we have a medical association established right in the heart of the workings, an association which reports fully all interesting or unusual cases, and whose proceedings are even published by an official press situated in the Canal Zone. The text of the books is varied and valuable: too varied to comment on here. But they are remarkable as evidence of the success that follows a policy often wrongly described as genius—an infinite capacity for taking pains.

MEDICAL EQUIPMENT OF CAPT. SCOTT'S EXPEDITION.

The official report by the Surgeons to the British Antarctic Expedition, 1910, upon the medical equipment, has been received and reads as follows:—

British Antarctic Expedition, 1910, July 18th, 1913.

"The complete satisfaction derived from the medical equipment supplied to the National Antarctic Expedition, 1902-1904, guided us in selecting Messrs. Burroughs Wellcome and Co. for the sole supply of medical equipment. This equipment consisted entirely

---

(*a*) "Annual Report of the Visiting Committee on the Croydon Mental Hospital for the Year ending March 31st, 1912."

(*b*) "Proceedings of the Canal Zone Medical Association." Vol. IV., Part I., April to September, 1911; Vol. IV., Part II., October, 1911, to March, 1912.

of 'Tabloid' medicine chests and cases, and 'Tabloid' medicines, and we have to report that the good opinion previously formed was maintained. The equipment was absolutely complete and perfect in every detail, and the 'Tabloid' products retained their full activity under trying and varying conditions of climate and transport. The actual 'Tabloid' equipment designed by the late Dr. E. A. Wilson for the Southern journey, and carried to the Pole, is being returned to you, with its remaining contents, which are in perfect condition."

An interesting photograph of the case actually carried to the Pole is reproduced in the accompanying illustration.

REVIEWS OF BOOKS.

RECENT WORKS ON PATHOLOGY.

It is not long since the number of text-books on pathology written in English could be told on the fingers of one hand. Now they are as plentiful as blackberries, and, let us add, most of them as excellent as that succulent fruit. Their very number, however, compels us to limit the space we can devote to each, and we therefore have to notice in this review not only some recent text-books, but also some other works dealing specially with pathology.

The first on our list (*a*) is a book which, in its older form, was for a quarter of a century a favourite text-book. Professor Woodhead's "Practical Pathology" had been, however, for many years out of print, and during that time pathology had become almost a new subject. On its practical or technical side but little of the old skeleton remained. In preparing a fourth edition, Professor Woodhead had almost to write a new book. He wisely decided, however, to follow the same lines as in the original work. The book is strictly and logically a practical work. It gives clear and definite directions on the various points of *technique*, so that it is admirably suited as a class-book for laboratory use. It is not, however, concerned exclusively with *technique*, but it gives, in addition, terse descriptions of the various naked-eye and minute appearances met with in the study of morbid anatomy and histology. When we add that the pictures are not only the best in execution, but most illustrative of their subject, our readers may be satisfied that the present generation of students and practitioners is, like the last, deeply in Professor Woodhead's debt.

Drs. Adamii and McCrae's "Text-Book of Pathology" (*b*) is avowedly and, indeed, necessarily, based on Professor Adami's recent work on the "Principles of Pathology." Its scope and intention are, however, quite different, and it should secure a class of readers among those who would be scared from the larger work by the mere fact of its exhaustiveness. In the treatment of general pathology the present work follows closely, though with much less detail, on the lines of the "Principles," but in regard to special pathology the authors have given themselves a freer hand. The result as a whole is satisfying. If one were not acquainted with the larger work, one would never detect from the reading of this that it was in any sense an abridgment. The writers properly devote half their space to questions of general pathology. For knowledge of this a student must rely on his text-books, since even the most thorough lecturer can hardly do more than furnish the framework with which the knowledge is to be fitted. Special pathology, on the other hand, is learned in the main from the study of gross and microscopic specimens, the text-book being only ancillary. As is to be expected in a book in whose making Prof. Adami has a hand, the subject of Inflammation receives adequate treatment. The twenty-five pages devoted to Immunity give as satisfactory a summary of present knowledge as can be expected. An unusual, but very valuable feature in a book of the sort is a section on Pain, which is somewhat fancifully defined as "the cry of the tissues." The greater part of the section is devoted to an explication of the fact that pain as felt is always referred, whether the reference be accurate or not. The sections dealing with special pathology are on the whole careful and methodic, though in a few instances—*e.g.*, in the discussion of tumours of the uterus—they may tend to be "sketchy." The drawings are pleasing, and, unlike some so-called "illustrations," they really illustrate the subject dealt with. The book should take a leading place as a student's text-book.

"The Text-Book of General Pathology" (*a*) is, so far as we know, the first book on pathology written on this plan in English. Joint authorship has certain disadvantages, chiefly in what we may call the architecture of a book, but it has great advantages, in that each contributor can be given a subject on which he is able to speak with authority and first-hand knowledge. The editors have been judicious and fortunate in getting their team together. In addition to the editors themselves, the following have contributed articles:—Drs. A. P. Beddard, A. E. Boycott, C. H. Browning, A. E. Garrod, J. S. Haldane, I. Walker Hall, A. F. Hertz, F. W. Mott, J. H. Ryffel, S. V. Sewell, J. Lorrain Smith, and E. Ainley Walker. The general intention of the editors has been to show the close dependence of pathology on physiology, "that the laws of disease are really the laws of health, and lack of co-ordination between the normal activities of the component tissues of the body is often the most important factor in the origin of disease." It is in the hope of elucidating this principle that the editors have called to their aid not only professed pathologists, but physiologists and practising physicians. The result is a book which presents to the reader the principles of pathology in the most complete form that is justified by the latest researches. It is naturally not arm-chair reading, nor is it intended for the beginner, but to any medical man who takes an intelligent interest in what used to be called "the institutes of medicine," the scientific groundwork on which practice is based, we can recommend no better book.

The intention of Dr. Julius Bernstein's book on "Applied Pathology" (*b*) is to give to practitioners and senior students a survey of the applications of clinical research. It is based on the lectures on clinical pathology delivered by the author at the West London Post-Graduate College. Dr. Bernstein sees much to regret in the present position of the clinical pathologist, who is usually a pathologist with little knowledge of clinical medicine. He looks to the future to see the physician develop into a physician-pathologist, who will be equally at home at the bedside and in the laboratory. We agree in hoping for the advent of such a character. The difficulty is, however, to know whether he will be a pathologist turned physician, or a physician turned pathologist. Dr. Bernstein's book, if read, will undoubtedly give the practitioner a good view of what he may gain by the assistance of the clinical pathologist, but the difficulty will be to persuade him to read it. The author too often forgets that he is not writing a laboratory hand-book, and he degenerates into details of *technique*. Moreover, the publishers have hardly helped him much. The volume is unpleasant in appearance and unduly heavy. Dr. Bernstein's discussions, nevertheless, are clear and his opinions sound. His choice of words may give rise to criticism. We know no justification for such a monstrosity as

---

(*a*) "Practical Pathology," a Manual for Students and Practitioners. By G. Sims Woodhead, M.A.Cantab., M.D.Edin., Hon. LL.D.Toronto. With 275 coloured illustrations. 4th edition. Pp. xxii. and 798. London: Henry Frowde; Hodder and Stoughton. Price 31s. 6d. net.

(*b*) "A Text-book of Pathology for Students of Medicine." By J. George Adami, M.A., M.D., F.R.S., and John McCrae, M.D., M.R.C.P.Lond. Illustrated with 304 engravings and 11 coloured plates. Pp. x. and 759. London: Macmillan and Co., Ltd. Price 25s. net.

(*a*) "Text-book of General Pathology." By Fourteen Contributors. Edited by M. S. Pembrey and J. Ritchie. Pp. xii. and 773. London: Edward Arnold. 1913. Price 18s. net.

(*b*) "Applied Pathology." By Julius M. Bernstein, M.B.Lond., D.P.H.Camb., M.R.C.P. Illustrated. London: University of London Press; Hodder and Stoughton; and Henry Frowde.

"serology," which is the heading of one of his chapters; nor do we think that a consulting physician should be described as an "addendum" to the general practitioner. In his discussion of vaccine therapy, the author unduly depreciates the use of vaccines in septicæmia; he is evidently not acquainted with recent work on the use of vaccines in puerperal sepsis. Nevertheless, in the main Dr. Bernstein's work is sound and interesting, and we hope he may have many readers.

PROFESSOR GRUNBAUM'S book on *Morbid Histology* (*a*) avowedly follows the lines of Sir Edward Schäfer's *Essentials of Histology*, and a better model could not have been chosen. The book is intended to assist in the teaching of general rather than of special pathological anatomy. The descriptions are clear, terse, and dogmatic. The selection of subjects could hardly be bettered, though, of course, every teacher proceeds on his own lines. The subjects of the illustrations, which, in a student's book for use with the microscope, are of primary importance, have been carefully chosen from typical sections, and the illustrations have been well executed. A few pages are given to methods.

IT is quite true, as Dr. Shennan says, in the preface to his book (*b*), that it is unusual for a student of medicine to carry with him into practice a knowledge of *post mortem technique* sufficient to enable him to conduct a *post mortem* examination creditably. This is a matter which teachers of pathology should remedy, and, if they set themselves to it, they will get much help from Dr. Shennan's book. After a general chapter on the *post mortem* examination, one on the external examination of the body, and one on the internal examination, Dr. Shennan takes in turn the several regions of the body, describing in detail the morbid anatomy of the various conditions likely to be encountered. His treatment is adequate, and the practitioner who knows Dr. Shennan's book will be competent to carry out an autopsy in an intelligent and satisfactory manner. The book is large, however, and is more likely to be used as a work of reference than for ordinary reading. As a work of reference it should be in the *post mortem* room of every hospital, or within easy reach of the resident, on whom the duty often falls of making a *post mortem* examination. The illustrations, most of which are photographs of actual specimens, add to the value of the book. Many of them fulfil all the functions of illustrations, and demonstrate the required points as well as could be done by drawings. The photographs of amyloid liver (Fig. 113) and nutmeg liver (Fig. 115), for example, are excellent. On the other hand, some give no enlightenment. Fig. 122 of cirrhosis of the liver is from a specimen spoiled by drying, and gives a fictitious appearance of excessive and remarkable pigmentation! The general success of the photographs is, however, remarkable. Dr. Shennan in a brief appendix gives useful directions for the preservation of tissues. We cannot leave this excellent book without declaring that there is no excuse for its title; the term "*post mortem*" is not a substantive.

GYNÆCOLOGICAL DIAGNOSIS AND PATHOLOGY. (*c*)

CONSIDERING the importance of the subject, there are singularly few books in English dealing with gynæcological pathology. The references in text-books of pathology are usually meagre, and the paragraphs dealing with pathology in text-books of gynæcology prehistoric in their stage of knowledge. We extend, therefore, a cordial welcome to Drs. Barbour and Watson's "Gynæcological Diagnosis and Pathology." As there is already adequate attention paid in other books to questions of diagnosis other than those based on pathological findings, our chief interest is in the sections dealing with pathology. The book is arranged in anatomical sequence, conditions of the uterus, the tubes, the ovaries, the parametrium, the vagina, and the vulva being dealt with in turn. The treatment of endometritis is sensible. Having given a brief notice of acute endometritis, the authors next describe glandular hyperplasia, the so-called "chronic endometritis." While we agree that this change is certainly not purely inflammatory, we cannot agree that it is of the nature of a new growth, or that "it is really a simple adenoma." Nor do we agree that the change known as interstitial endometritis is merely a part of the much rarer condition of fibrosis of the uterus. We find no mention of cystic endometritis, a condition associated with a fairly definite group of symptoms. It is stated (p. 83) that "the diagnosis of chorion-epithelioma is made by the recognition of the two types of chorionic cells—Langhan's cells and the syncytium," forgetful of the fact that syncytial cells may be altogether absent. In describing degenerative changes in fibroids, the statement is made that necrobiosis or red degeneration "is probably the commonest degenerative change met with in fibroid tumours." Necrobiosis is certainly very common, but not five per cent. of necrobiotic changes can be described as red degeneration. We miss any mention of dropsical or of fatty changes, both of which are common. There is an excellent chapter on tubal pregnancy, but we find no mention of other forms of ectopic pregnancy. A requisite warning is given as to the potential malignancy of papillomatous cysts of the ovary. In the description of conditions of the vagina we miss any mention of cysts, and in relation to the vulva of any malignant tumour other than epithelioma, though adeno-carcinoma of the vulva presents certain interesting features. The work is copiously illustrated; the illustrations appear to be from photographs, and many of them are lacking in definition. In the illustrations of microscopic preparations the magnification is not stated. Our criticisms have all been directed to matters of detail, for in the main the book maintains a high level of excellence. It should be read with care by every practising gynæcologist. We congratulate the authors on producing so useful and desired a work.

MALFORMATIONS AND DISEASES OF THE FŒTUS (*a*)

OUTSIDE Dr. Ballantyne's writings, very little exists in English dealing systematically with prenatal pathology, and we therefore welcome Dr. Blacker's translation of Professor Birnbaum's book on "Malformations and Congenital Diseases of the Fœtus." The author treats in order of the various regions of the body, and the translator has aided us in understanding the anomalies dealt with by reference to the facts of normal embryology. The book has a special interest to obstetricians in that due attention is given to questions of diagnosis and treatment. Notice is taken also of injuries to the child occurring at or near birth. There is an interesting, if brief, chapter on the legal rights of monsters, a subject on which it is hard to glean information from the medico-legal text-books. It appears that in England, according to Blackstone, if a monster "hath human shape" it can inherit, but if it "hath not the shape of mankind, but in any part bears the resemblance of the brute creation," it has no legal status. In Germany, on the other hand, anything born of a woman has legal rights. The question may be of some importance in the cases of tenancies for life depending on the birth of a live heir. Again, questions as to the determination of sex are of frequent occurrence; some three persons a year on an average apply to Somerset House to have the record

---

(*a*) "The Essentials of Morbid Histology for the Use of Students." By Albert S. Grünbaum, M.A., M.D., F.R.C.P. With 22 coloured plates and 139 other illustrations. Pp. xvi. and 219. London: Longmans, Green and Co. Price 7s. 6d. net.

(*b*) "Post-Mortems and Morbid Anatomy." By Theodore Shennan, M.D., F.R.C.S.Edin., Pathologist to the Royal Infirmary, Edinburgh, etc. Pp. xvi. and 496. London: Constable and Co. Price 18s. net.

(*c*) "Gynæcological Diagnosis and Pathology." By A. H. F. Barbour, M.D., LL.D., F.R.C.P.Edin., and B. P. Watson, M.D., F.R.C.S.Edin. With 8 plates and 202 figures. Pp. xvi. and 220. Edinburgh: William Green and Sons. Price 7s. 6d. net.

(*a*) "A Clinical Manual of the Malformations and Congenital Diseases of the Fœtus." By Prof. Dr. R. Birnbaum. Translated and annotated by G. Blacker, M.D., B.S., F.R.C.P., F.R.C.S., with 38 illustrations in the text and 8 plates. Pp. xiv. and 379. London: J. and A. Churchill. Price 15s. net.

of their sex altered. In discussing the case of the Siamese twins, the curious remark is made: "As the two twins have an active interchange of the fluids of their bodies, the vaccination of one would no doubt suffice. We may suppose, however, that baptism would have to be administered to both."

HOW TO DIAGNOSE SMALL-POX. (a)

The difficulty of diagnosis in the case of small-pox, especially when modified by vaccination, is well-known, and it is to be constantly borne in mind that we are not dealing with a suspected case of small-pox in its natural form, and that many of its characteristic features are not to be found. The volume under review, by Dr. Wanklyn, an Officer of the Metropolitan Asylums Board, and who has had an exceptional experience of this disease, is of real interest. In the opening chapters accounts are given of outbreaks due to errors in diagnosis from an unsuspected case, more especially with regard to measles and chicken-pox, and the result being that measures for the prevention of its spread have not been undertaken. In the chapter relating to practical points in the method of examination stress is laid on the following important points, namely, that small-pox should always be borne in mind, and that the whole surface of the body should be seen as far as possible at the same time, and in a good light, also emphasising the point that a hot bath may bring out a rash, previously undiscoverable.

In the chapter discussing cases with a view to diagnosis, the points which are to be relied upon are clearly and definitely defined.

The aim of the book is to assist the reader to recognise that disease whatever its appearance. It most certainly accomplishes its object, being a piece of honest, solid work, skilfully arranged and well elaborated, and should be on the bookshelf of every public health authority.

MEDICAL NEWS IN BRIEF.

Medical Sickness and Accident Society.

The usual monthly meeting of the Executive Committee of the Medical Sickness, Annuity and Life Assurance Society was held at 429 Strand, London, W.C., on Friday, September 19th, Dr. F. J. Allan in the chair. Contrary to expectation, the summer months have shown very little falling off in the claims, and the experience has been heavy and slightly over the expectations. New business was well up to the average, and the steady growth of proposals for additional benefits received indicates the satisfaction of members with the Society.

The half-yearly balance sheet considered at this meeting showed that the reserves are now just on £260,000, and each fund shows an increase. The actual amount spent on management for the half-year was 5 per cent., and the economy practised in this department has been one of the great factors of the Society's success.

A letter was read from the widow of a member, expressing her thanks for the grant made, through the Society's recommendation, by the Royal Medical Benevolent Fund, and asking for support for her son's election to Epsom College next June. The Society subscribes largely to these two institutions, and has been instrumental in obtaining many foundation Scholarships for the sons of deceased members, and grants of money for their widows.

Mosquitoes in Epping Forest.

Mr. W. E. Rowe, Chingford Urban District Council, presided over a conference held last week at the offices of the Essex County Council, Broad Street Place, to consider the best means of exterminating mosquitoes in the neighbourhood of Epping Forest. Representatives were present from Buckhurst Hill, Chingford, Leyton, Longton, Wanstead, Woodford, Epping, and the Epping forest Committee.

Dr. Stanbury Brook (Medical Officer of Health for Chingford) read a report prepared by Dr. Edward Halford Ross, of the John Howard McFadden Research Fund at the Lister Institute of Preventive Medicine, on the results of investigations carried out in the district. After describing the life-history of the mosquito, Dr. Ross said that while it did not spread fevers in this country, it set up inflammation, and sometimes blood poisoning, abscess formations, etc. He absolved Epping Forest itself to a great extent, and stated that he found that the mosquitoes were bred principally in water-butts, tubs, fountains, and in small quantities of water collected in private gardens.

Dr. Brook argued that on this report the remedy lay in the direction of abolishing those receptacles, or, at any rate, the emptying of them once a week; the filling up of unnecessary pools and wells; the clearing of obstructions from small rivers, etc.; the spraying of large ponds with oil, or the introduction of mosquito egg-eating fish, which could be obtained from Kew Gardens. Bats and swifts, which fed upon the mosquitoes, might also be employed. Above all, he urged that they should appeal to the private householders in the neighbourhood of Epping Forest.

After some discussion it was resolved to take measures for exterminating the pest, and a committee was appointed to consider the matter further.

New Hospital at Dollis Hill.

A new hospital, known as St. Andrew's Hospital, Dollis Hill, was opened last week by the Lord Mayor of London. The Institution overlooks a large expanse of open country on the east and north, while to the south stretches Gladstone Park. It is the gift of a French Roman Catholic lady, who wishes to remain anonymous until after her death, and has been built under the patronage of Cardinal Bourne. The principal object is to provide for people who are unable to pay the fees charged at the more expensive hospitals and nursing homes. At St. Andrew's a charge of 2½ guineas a week will be made, this being entirely inclusive. The new building has accommodation for 100 patients, but at present only 50 beds are occupied. Donations are needed to extinguish a debt of £10,000. The care of the institution has been entrusted to the Congregation known as "The Poor Servants of the Mother of God."

Treatment of Tuberculosis in the Isle of Wight.

The Local Government Board having sent several communications to the Isle of Wight County Council with reference to the provision of a scheme for the treatment of tuberculosis, the General Purposes Committee of the Council have decided to reply that it is not considered necessary to take any steps at present, either for the provision of dispensaries or the establishment of a sanatorium, and that in the opinion of the medical representatives there is at present no necessity for the appointment of a tuberculosis officer.

St. Bartholomew's Hospital and College.

The following awards to entrance scholarships have been made:—

Entrance Scholarship in Arts.—£100 for one year to James Dick, of Epsom College, and Leonard Duncan Porteous, of Huddersfield College (equal).

Jeaffreson Exhibition.—£50 for one year to Rowland John Perkins, of Bedford Modern School.

St. Mary's Hospital Medical School.

The following awards have been made as the result of the competitive examination:—

University Scholarships of 50 guineas each.—S. C. Dyke, B.A., Exeter College, Oxford; W. H. Thomas, University College, Cardiff.

Open Scholarships in Natural Science.—£75, A. J. Cokkinio, International College, Smyrna; £75, G. V. Davies, Epsom College.

Palmer Scholarship of £25 guineas.—G. MacAlevey, Mount St. Mary's College, Chesterfield.

Epsom College Scholarship (by nomination).—B. Thomas.

(a) "How to Diagnose Small-Pox." By Dr. W. McC. Wanklyn. London: Smith, Elder and Co.

NOTICES TO CORRESPONDENTS, &c.

☛ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial,* and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Mr. R. Cox (London, S.W.).—The first *London Pharmacopœia* was published by the Royal College of Physicians in 1618, and numerous other editions appeared between that date and 1836. The first *Edinburgh Pharmacopœia* was published in 1699, and the first *Dublin Pharmacopœia* in 1794. The first *British Pharmacopœia* was published in 1864, under the direction of the General Medical Council.

BRITISH HOSPITAL FOR MENTAL DISORDERS AND NERVOUS DISEASES.—"FORBES WINSLOW MEMORIAL."

We are informed that, owing to the death of Dr. Forbes Winslow, the above hospital is under the management of a new lay executive committee and is being entirely re-organised. An increased medical staff has been appointed, and as soon as the lease of the present building at 72, Camden Road, N.W., expires, new premises will be found. There have been on an average three thousand borderland cases treated annually, and it is hoped that under the new auspices the usefulness of this institution will be considerably increased. The hospital is free to the indigent poor, and is supported by voluntary contributions.

Erratum.—In the letter by Mr. A. A. Bradburne (Manchester), printed in our issue of the 24th ult., L.R.C.S. should have been F.R.C.S. We regret the error, which was made inadvertently.

Dr. T. S. (Somerset).—There is no reason why salvarsan should always be given by the same route. Quite recently, Wechselmann has reported a series of one thousand cases in which neosalvarsan has been injected into the area around the great trochanter directly over the fascia, care being taken not to inject it into the fascia, fat, or muscle. It is said that by this method there are no complications, such as necrosis. Full details are given in the *Muench. Med. Woch.* No. 24, 1913.

Meetings of the Societies Lectures, &c.

Thursday, October 2nd.

North-East London Clinical Society (Prince of Wales's Hospital, Tottenham, N.).—4.15 p.m.: Opening address by Dr. J. G. Risien Russell.

Friday, October 3rd.

West London Medico-Chirurgical Society (West London Hospital, Hammersmith, W.).—8 p.m.: Presidential address by Dr. F. S. Palmer.

Appointments.

Butler, T. Harrison, M.D., B.Ch.Oxon., Assistant Surgeon to the Birmingham and Midland Eye Hospital.

Dickson, William Arnett, M.D.St. And., F.R.C.S.Edin., D.P.H., County Tuberculosis Medical Officer to the Joint Committee of the Gloucestershire County Council and Gloucester City Council.

Heaton, G., M.B., Ch.B.Oxon., F.R.C.S.Eng., Consulting General Surgeon to the Birmingham and Midland Eye Hospital.

Hird, R. Beatson, M.D., B.Ch.Birm., F.R.C.S.Edin., Assistant Surgeon to the Birmingham and Midland Eye Hospital.

Johnston, M. J., M.B., Ch.B.Edin., Tuberculosis Officer for West Sussex.

Jones, J. P., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory and Workshop Acts for the Barmouth District of the county of Merioneth.

Kelynack, T. N., editor of "The British Journal of Tuberculosis" and of "The Child," Hon. Physician to the well-known Ragged School Union and Shaftesbury Society.

McColl, Eva, M.D.Glasg., D.P.H.Camb., School Medical Officer of Jarrow.

Peake, H. G., M.B., Ch.B.Vict., House Physician at the Salford Royal Hospital.

Pitt, Oswald, M.R.C.S., L.R.C.P.Lond., House Surgeon at the Salford Royal Hospital.

Smith, D. Priestley, M.B., B.Ch.Birm., Assistant Surgeon to the Birmingham and Midland Eye Hospital.

Todd, Alan H., M.B., B.S., B.Sc.Lond., F.R.C.S.Eng., Surgical Registrar and Tutor and Staff Anæsthetist at Guy's Hospital.

Vacancies.

Argyle and Bute Asylum, Lochgilphead.—Assistant Medical Officer. Salary £160 per annum, with furnished apartments, board, and laundry. Applications to the Medical Superintendent.

Anæsthetist to the Royal Infirmary, Dublin, and Instructor in Anæsthetics in the University of St. Andrews. Salary £200 per annum. Applications to the Secretary of the Royal Infirmary, Dundee.

James Murray's Royal Asylum for Lunatics, Perth.—Physician-Superintendent. Salary £700 per annum, with furnished house and emoluments. Applications to Condie, Mackenzie and Co., W.S., Perth.

Middlesex County Asylum, Wandsworth, S.W.—Third Assistant Medical Officer. Salary £200 per annum, with full board, lodging, etc. Applications to the Medical Superintendent.

North Ormesby Hospital, Middlesbrough.—Assistant House Surgeon. Salary £100 per annum, with board, apartments, washing and attendance. Applications to E. C. Smith, F.C.I.S., Secretary.

The Hospital for Sick Children, Great Ormond Street, W.C.—Assistant Casualty Medical Officer. Salary for six months £30, washing allowance £2 10s., with board and residence in the Hospital. Applications to the Secretary (see advt.).

Eastern Dispensary, Leman Street, E.—Resident Medical Officer. Salary £120 per annum, with furnished residence and attendance. Applications to the Secretary.

Whitehaven and West Cumberland Infirmary.—Resident House Surgeon. Salary £120 per annum, with board and lodging. Applications to H. J. Bewlay, Secretary.

County Asylum, Whittingham, Preston, Lancs.—Assistant Medical Officer. Salary £200 per annum, with board, furnished apartments, and washing. Applications to the Medical Superintendent.

Births.

Chater.—On July 18th, at New Hanover, Natal to Dr. and Mrs. T. A. Chater—a son.

Derry.—On September 25th, at "Windspoint," Higher Drive, Purley, Surrey, to Dr. and Mrs. D. E. Derry—a daughter.

Dunnett.—On September 29th, at 3 Ascott Avenue, Ealing, W., Agnes Dunnett, M.B.Lond., wife of Lionel Francis Dunnett, of a son.

Griffin.—On September 22nd, at Baldock, Herts, the wife of John P. Griffin, M.R.C.S., L.R.C.P.Lond., of a daughter.

Mason.—On September 27th, at Toll House, Great Bridge, Staffordshire, to Dr. and Mrs. Philip Mason—a son.

Phillips.—On September 20th, at Bethlem Royal Hospital, London, to Dr. and Mrs. Porter Phillips—a daughter.

Thornley.—On September 27th, at Ravensdene, Scarborough, the wife of Dr. J. Hardwick Thornley, of a daughter.

Wilson.—On September 25th, at Murree, Punjab, India, to Captain and Mrs. N. Methven Wilson, I.M.S.—a daughter (Margaret Helen).

Woodyatt.—On September 22nd, at the Infirmary, Vallance Road, London, N.E., to Dr. and Mrs. Woodyatt—a son.

Marriages.

Bowring—Lewis.—On September 27th, at Shoreham, Walter Andrew Bowring, F.R.C.S., of Brighton, to Margaret, widow of Rev. E. T. Lewis, and younger daughter of Rev. H. Rowsell, late Vicar of Christ Church, Mayfair, W.

Caley—Briggs.—On September 27th, at St. John the Baptist's Church, Knighton, Leicester, F. Goodman Caley, M.B., eldest son of Hugh A. Caley, of Windsor, to Edith Martha, youngest daughter of the late Joshua Briggs, of Headingley, Leeds.

Forrest—Child.—On September 20th, at All Soul's Church, South Hampstead, Captain Frank Forrest, R.A.M.C., to Maude Adelaide, youngest daughter of John and Amelia Child, of 2 Welch Road, Hampstead.

MacPhee—Soanes.—On September 27th, at Southampton, Burgess MacPhee, M.B., Ch.B., D.P.H., eldest son of Stephen A. MacPhee, of Pollokshaws, Glasgow, to Daisy Marion, elder daughter of Mrs. Soanes, Bournemouth.

Mills—Roberts.—On September 23rd, at St. James' Episcopal Church, Inverleith Row, Edinburgh, Horace Macaulay Mills, M.B., Ch.B., Elsecar, near Barnsley, youngest son of Mr. and Mrs. John Mills, The Avenue, Clifton, Bristol, to Gladys Helen, younger daughter of Mr. and Mrs. Edward A. Roberts, 26 Dick Place, Edinburgh.

Deaths.

Ashe.—On September 21st, at Langley, Bucks, William Percy Ashe, M.D., aged 62.

Hartill.—On September 23rd, at Manor House, Willenhall, John Thomas Hartill, L.R.C.P.Lond., M.R.C.S., J.P., aged 65.

Norris.—On September 24th, at Langley Lodge, Surbiton, Florence Emily, wife of Frank B. Norris, M.D.

Roxburgh.—On September 25th, at Weston-super-Mare, Eliza Fanny, beloved wife of Robert Roxburgh, M.B., F.R.C.S.E.

Spearman.—On September 15th, at Clacton-on-Sea, Robert Spearman, M.A., M.B., B.C.Cantab., aged 36.

Williams.—On September 19th, at Castle Hill, Holywell, Flints, James Williams, M.R.C.S.Eng., L.S.A.Lond., aged 88.

Wilson.—On September 23rd, at The Corner House, Southwold, Francis Kenneth Wilson, M.B., B.S.Lond., aged 43.

Wood.—On September 23rd, at Sunny Bank, Broad Oak, Heathfield, Sussex, Alice, the beloved wife of Henry Thorold Wood, M.R.C.S., passed peacefully away in sleep, after a long illness patiently borne. Aged 58.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVII. WEDNESDAY, OCTOBER 8, 1913. NO. 15.

NOTES AND COMMENTS.

The Wandsworth B.M.A. Resolution.

THE medical profession has yet to learn the art of collective bargaining and to acquire the fundamental principles of unionism. Better proof of that assertion could hardly be required than the actions of the Wandsworth Division of the B.M.A. in advising their fellow members who disapproved the pro-panel policy of the Association forthwith to resign. In other words, a little knot of extremists wish to wreck the Association because they do not approve the reversal of the non-panel policy which at the close of last year dominated that body. If one attempts to trace the origin of the trouble it will probably be found in the pledge that was imposed upon members at an early stage of the proceedings. The terms of the compact were concise and stringent and the impossibility of enforcing them was made evident in the stampede at the end of December, 1912. Pledge or no pledge, the majority of members flocked to the panels and a change of attitude on the part of the Association followed as a matter of course. It is part of the irony of the situation that Dr. Cox had to account for and excuse that *volte-face* to the non-panel malcontents of the Wandsworth Division. If members cannot subordinate their individual views to the judgment of the majority they become at once a source of weakness to the Association, and their only logical course is immediate resignation. Meanwhile we are glad to believe that the B.M.A. will emerge a stronger and wiser body as the result of the past few years' experience.

The Medical Register.

ELSEWHERE in our columns appears the annual appeal issued to the profession by the Registrar of the General Medical Council. He asks all men on the *Register* to see that their names and addresses are accurately recorded therein. Any practitioner who may have a doubt as to the accuracy of the details published regarding him should communicate at once with the Registrar, 298, Oxford Street, London, W. As the *Register* is the only official publication it is obvious that any error of description may cause a considerable amount of inconvenience when the medical man thus wrongly described is called upon to sign documents in a professional capacity, or to discharge any of the functions that particularly appertain to legal medical qualification. A warning is issued by the Council as to the signing of certificates that may subsequently be made use of in courts of justice or for administrative purposes. It goes without saying that great circumspection should be exercised before signing any responsible documents of the kind.

Council Reforms.

THE solicitude shown by the General Medical Council in this matter suggests a regret that their duties do not extend over a wider range of activities. The Council is the only body that enjoys the privilege of presenting its views officially to the Government, owing to its connection with the Privy Council. So far the fruits of that high official relationship have as a rule been conspicuous by their absence. There are certain reforms that if carried out could hardly fail to prove of value to the medical profession. The Council, needless to remark, is cramped by lack of funds. Why should not registration be made compulsory upon all medical men, and why should it not be maintained by the imposition of a small annual fee? The lawyers have adopted that wise and simple course; why should not the doctors follow suit? If the General Medical Council were to start a vigorous campaign in favour of this and a few other reforms they would probably be able to get them through Parliament at the cost of a few years' insistence. It is to be feared, however, that the Council will not shake off its slough of *laisser-faire* conservatism so long as its constitution remains practically that of a non-elected and non-representative, irresponsible body.

Railway Sanitation.

A MEDICAL man has sent us a letter dealing with the subject of railway sanitation. He agrees generally with the remarks that have recently been made by various correspondents and particularly as to the evident lack of supervision by local sanitary authorities. No one, by the way, has so far answered our request for information as to the legal position of railway companies with regard to local medical officers of health. The point is one that must frequently have arisen. It seems unthinkable that so practical a nation as our own in matters of health administration can have overlooked so important a detail. Our correspondent has made it his duty to look into the sanitary arrangements at certain provincial railway stations. He reports a state of affairs that in some respects is truly deplorable. Urinals without a continuous water flush are of common occurrence; some of the water-closets are dirty, their pans filthy and their atmosphere redolent with sewer gas. Another legal point raised by our correspondent is whether a railway company is not forced by Act of Parliament to provide free closet accommodation for passengers. It seems hardly fair that the company should treat the daily needs of life as a source of income. Later we hope to discuss the whole subject of railway hygiene somewhat exhaustively.

Medical Portraits and Proprietary Advertisements.

Recently some of the London daily newspapers have issued advertisements of a nature objectionable on various grounds to the medical profession. A proprietary cure for asthma contains a quotation from the works of the late Sir Morell Mackenzie, together with a cabinet-size photograph of that distinguished specialist. The advertisement deals with a "safe and permanent cure" for asthma. As no such remedy is known to medical science, and, indeed, it is inconceivable that any single drug, or combination of drugs, would achieve such a result, while, on the other hand, asthma itself is in many cases a hopeless and incurable condition, it is clear that the "cure" is not one whose advertisement claims can be substantiated in any court of medical appeal. To insert the name of one of our great medical men with such an advertisement, therefore, is to put upon his memory a slight that is intolerable. Why should not the General Medical Council bestir itself with regard to this point? Why should it not represent strongly to the Government the desirability of a short Act rendering the use in advertisements of the name of a deceased medical man a legal offence? The British Medical Association might take the matter up with advantage. If both bodies were to press the point vigorously and repeatedly in the proper quarters the desired alteration would probably be effected within a reasonable compass of time.

Dr. Dunlop's Side of the Question.

Elsewhere in our columns will be found some editorial comments on the case of the panel doctor who was compelled to pay damages and costs for non-attendance on a patient to whom he was summoned. This paragraph is added here, as it would not be fair to Dr. Dunlop if his side of the case were not fully stated. A good report of the action is given in the *Liverpool Daily Post* of October 3rd. According to counsel for defendant the first message reached him about 12.30 p.m., when the doctor had started on his rounds. On returning at 3 p.m. he noted the call. He then had dinner and attended his surgery from 3 to 4, after which he had a cup of tea. At 5 o'clock a Miss Kelly called and he said he would go to the house. At half-past five, just as he was about to start, two sisters of the plaintiff came and insisted upon his going with them at once. He was nettled by their manner, and because he did not at once comply they said he need not come at all, and they would get another doctor. The doctor took that as his dismissal and did not consider the case any more. It seems clear from the facts elicited that the doctor had an extremely busy day and that he objected to what he considered the peremptory nature of the call. One moral to be gathered from the incident is that the lot of the medical man with a large panel is not altogether a bed of roses. Trouble seems to arise pretty often from the late messages, that is to say, those that come after the doctor has started on his morning round. It would be a good plan were the Insurance Committee of every large district to appoint an extra panel doctor, so to speak, for the sole purpose of attending emergencies and of relieving panel doctors during such times of great pressure as must arise in all contract practice.

LEADING ARTICLES.

METHODS OF MEDICAL EDUCATION.

Of general education it may be permitted to express the doubt that our national methods are still open to a good deal of improvement. Technical instruction, nature study, subjects specially fitted for the individual capacity and bent, and other important departures are being assessed at a rapidly increasing value by our educational authorities. The modern schoolmaster, in spite of the inherent conservatism of his profession, is in fact translating his work more and more into terms of science and abandoning the time-worn traditions of fashion and theory. To state the matter broadly, education is undergoing that process of evolution inevitable to all human institutions. Nor is the spirit of change less evident in the field of medical education, with which our readers are more directly concerned. In his recent opening address, Sir William Osler, one of the philosophic minds of modern medicine, had a good deal to say about the future of medical education. It is not proposed to follow his arguments in the present article, but all who are interested in the important subject with which he dealt will do well to ponder carefully not only his observations and suggestions, but to consider that which lies between the lines of his speech. One thing Sir William would abolish is the formal medical lecture, a suggestion that will be heartily endorsed by most students and many teachers. There is little taught in the ordinary class-room lecture that could not be equally well or better acquired by the average student from a book in the solitude of his own chamber. The circumstances of medical education are peculiar in the sense that the student has to acquire a large amount of theoretical knowledge on many subjects within a limited space of time. He has moreover to submit his acquirements periodically to the test of examination. Sir William Osler drew pointed attention to one defect in the present system, namely, the turning out of men filled with theories but untrained in the actual work at the bedside, which, after all is the supreme end and aim of the whole curriculum. The medical man whose career lies outside teaching or consultant work wants a practical knowledge which will enable him to meet all the ordinary conditions and emergencies of medical and surgical practice with benefit to his patients and justice to himself. To discharge that important function intelligently it is necessary for him to know the essential principles and elementary facts of a good many subsidiary sciences. How does our present system enable him to equip himself for practice on those lines? The answer to that question, it may be feared, is hardly satisfactory. The present plan of enormously detailed study and of high standard examination too often turns out a brilliant man of the schools, whose knowledge of practical work, however, may be hopelessly cramped, and whose aptitude for the responsible handling of disease, to put it bluntly, has not been proved. There are various factors bearing upon the situation that demand critical consideration other than those of the disproportions between theoretical and practical study, the advanced teaching of subjects indirectly concerned with the medical art, and high standard examinations. The most important of all, perhaps, is the ridiculous system which sanctions legal qualification by upwards of a score of rival corporations. With the advent of a one-portal system of medical qualification some of the difficulties, at least, of the present situation would probably vanish. It is to be regretted that the majority of hospital and medical school appointments are made subject to the holding of certain qualifications. The ultimate fitness of a man for responsible posts of the kind cannot be ascertained under the present plan of cramming for high standard examinations. The failure of medical education is to a certain extent registered in the recent development of post-graduate medical schools throughout the kingdom. It is to be regretted that the whole subject of medical education is not seriously considered by a great and capable professional organisation. In the absence of any such effect it might be advantageously investigated by means of a Royal Commission.

CURRENT TOPICS.

Cooking for Health.

Man is said to be "the only animal that cooks his food." One thing he, or rather she, does not do—she does not take advantage of modern methods in cooking to the same extent as she follows the fashions. The latter change like a kaleidoscope, whereas the former slowly evolve towards perfection. Even the proverbial "dinner of herbs" loses its savour if the stalks be tough and the colour of a weird mixture, for did a painter ever catch the unearthly hue presented by a badly cooked Brussels sprout? A great deal of domestic friction, not to say misery, would be saved if the art of cooking were systematically taught to elder scholars of all classes. It is not necessary to impart a knowledge of chemical physiology to the members of cookery classes, for all that is needed is to know how to prepare an appetising meal. Much labour can now be saved by the employment of gas cookers—a fact which was demonstrated last week at the National Gas Congress and Exhibition, held at Shepherd's Bush. Good cooking is almost as much an enemy of malnutrition as the selection of the proper kind of food—a fact which was well brought out by Dr. J. Priestley, Medical Officer of Health for Lambeth, in a popular introductory lecture. A gas cooker was exhibited, the invention of a barrister, which was said not only to solve effectually the problem of open fire roasting by gas, but also to enable a cook to bake pastry without an oven. The cooker consisted of six simple parts—namely, two grids, one horizontal burner, two side supports, and a radiating sheet, the whole weighing less than 6 lbs. A cookery demonstration described by the speaker comprised the roasting of a large fowl and a loin of lamb, the baking of a raised pie and a custard, the grilling of sausages, a large *sole au beurre*, stewed kidneys *au vin blanc*, soup, bread sauce, gravy, and a rum omelette, in addition to two vegetables. This comprehensive menu, Dr. Priestley stated, was cooked in two hours at a cost of one penny for gas. Whatever be the fuel adopted, the diet of all classes will be greatly improved by its scientific preparation and cooking, having due regard for the food value of each article.

The Real Dripping.

Some consternation must have been caused at the recent meeting of the managers of the Metropolitan Asylums District last week by the announcement that certain samples of dripping delivered to the Leavesden Asylum and Darenth Industrial Colony under contract were alleged to have come from a soap manufacturer. There is dripping and dripping. The genuine, wholesome stuff that actually "drips" from the joint during the process of roasting is of the right sort and possesses a flavour that is entirely its own. Moreover, it is a most valuable foodstuff for folk whose pockets are not well lined and whose larders cannot command the more costly and somewhat more æsthetic table fats, such as butter, cream and cheese. It is difficult to imagine what flavour the spurious "dripping" would have obtained from a soap manufacturer, though, as far as its real food value is concerned, it might not come far short of the genuine article. It was stated that the dripping was chiefly required for making pastry, and that it was preferred to margarine. This reminds us somewhat of the fate of the egg which is not good enough to appear at the breakfast table.

Then as Now.

We are prone to surround the past with a kind of mystic glamour. We do not give honour where honour is new, but reserve our panegyrics for times and methods whose inaccessibility denies all chance of refutation. For example, we think the middle ages knew something about toxicology. So they did, but not a tithe of what we vaguely give them credit for. The old apothecary was not a pocket Borgia. Men were asked out to dinner and they sometimes died after it. But *post cibos* is not necessarily *propter cibos*, and one man's meat was not always poison for another. There was not always death in the pot. If we look at a sixteenth-century menu we have a general feeling not of amazement that men should occasionally die after a banquet, but rather of surprise at the survivors. Then it is probable that modern surgery would have saved some of these moribund postprandialists—that perforation not poison ushered them into the *ewigkeit*. In fact, these terrible toxicologic tales suffer from exaggeration. The morality of the times demanded sudden death in a convenient form, and an alleged supply arose. It is much the same as if our day was judged by its patent medicine advertisements. Reading them a truthful age would sigh and offer illimitable gold for what we can buy for 1s. 1½d. As a matter of fact, we don't buy them. We know that some men are liars now, but we forget that there were liars in those days.

The Logical Conclusion.

There is no possible theoretical objection to carrying a thing or an idea to its logical conclusion. Practically it doesn't work. Attention has recently been drawn to what is called momentum in evolution, which means that where a function or organ has been found to be beneficial there is a tendency on its part to grow to excess till its very preponderance outweighs all possible advantages.

In the Glacial Period there was a tiger, and the tiger found it a good thing to have big teeth. So its teeth grew till somewhere in the late Pleistocene the sabre-toothed tiger found that its canines were large enough to make existence intolerable. So with the elks. They began with smooth heads and ended ingloriously with a twelve foot span of antler, so heavy that a drink frequently connoted death. We have brains. They are our outstanding feature, and they may swamp us. So far we are rather proud of them and they have certainly stood us in good stead in our fight with the rest of creation. Mind now triumphs over matter, but mind may not always triumph over itself. Our bodies are demonstrably worse than they were, and the danger is that we may get so good at controlling ourselves that we find we have nothing left to control. Mr. Wells has foreseen this in some of his stories, and his Martians are practically button-pressing cerebra. While it is good for us to think of where we may be tending there is no need for alarm. Let us look about us, at our neighbours, and all qualms will disappear. We shall not find enough signs of hypertrophic mentality to cause us a moment's unnecessary wakefulness.

Grinders' Phthisis.

IN dealing with such a widespread disease as consumption it cannot be too clearly stated that the health of workers in special trades largely depends upon themselves. Rules and regulations have their place, but unless these are complied with they become a dead letter. Certain occupations render the workers prone to develop tuberculosis, and the condition of the lungs resulting from the continued inhalation of dust can be seen any day in the pathological museums of our large hospitals. In attempting to reduce the prevalence of phthisis among the grinders of Sheffield an informal conference was held the other day in the Town Hall of that city under the presidency of the Lord Mayor. It was pointed out that during the years before the Home Office regulations became operative, the death-rate from tuberculosis amongst grinders was fifty per cent. The problem of how to reduce this high figure is two-fold. The dust must be scientifically removed by exhaust plants and the men themselves must use the apparatus provided for preventing the inhalation of dust and keep the exhaust machinery clean. Further intelligent co-operation of all concerned in the trade is urgently needed, and the absurd prejudice against wearing respirators should be overcome at all costs. The idea of holding dinner-hour lectures, or homely talks, upon general hygiene is a good one and it should go far towards popularising the official regulations which, after all, are issued entirely in the interests of the employees themselves. As Dr. Collis remarked, "He laughs best who laughs last, and it is better to be laughed at than to be buried." The substitution of emery stones or wheels for grindstones may be welcomed if it can be clearly shown that the change would materially reduce the danger to which the grinder is exposed in his daily work.

The Medical Needs of India.

IT was particularly appropriate that Surg.-General Sir Charles Pardey Lukis, K.C.S.I., Director-General, Indian Medical Service, in his opening address delivered at the London School of Medicine for Women last week, should have selected as his topic the consideration of some of the medical problems of our great Indian Empire. That Indian women still need the medical services of their European medical sisters is well known, but the work of the medical woman in India should not be confined solely to the care of women and children. As a matter of fact, a real need exists for the instruction of the female population of India in the laws of simple hygiene, especially in the matter of the prevention of disease, for in this way there is some chance of influencing the national health of the country. The systematic instruction of native midwives in modern midwifery, if undertaken by thoroughly-trained Europeans, should go far to reduce the still too high mortality from child-birth. Now that a service of medical women under the Central Committee of the Dufferin Association, known as "The Women's Medical Service for India," has been approved by the Government of India, the conditions under which medical women will be able to work will give this branch of the profession an assured and definite position. An immense sphere of work is now open to the highly-trained medical woman who wishes to devote her professional services to the physical betterment of Indian women. The fact that private practice is to be allowed, so long as it does not interfere with the performance of her official duties, and that the terms are better than those offered to young officers of the Indian Medical Service, should render the new service an attractive one to medical women in this country. The Government of India, realising the need for utilising indigenous talent, has given a site for the erection of an up-to-date medical college for women, with a hospital of 150 beds attached, at Delhi. This institution will be entirely staffed by women, and it will afford unrivalled opportunities for professional, tutorial and research work which could not otherwise be obtained.

Literary Medical Men.

IN his opening address at the Middlesex Hospital recently, Mr. Sampson Handley, in discussing with real insight the value of medicine as a liberal education, paid particular attention to the part medicine played in the training of medical men whose distinction came mainly outside the medical career. It was perhaps the fact that the present Poet Laureate was for several years a practising physician, which led Mr. Handley to his choice of a subject. From St. Luke to Sir Conan Doyle, medical men have won distinction as writers. Mr. Handley mentions in particular the great names of Goldsmith and Keats. He does not make any attempt to furnish a complete list, or the names of Arbuthnot and Smollett should not be omitted. Charles Lever, whose novels nowadays hardly attract the attention they deserve, was a medical man, who worked hard during the outbreak of cholera in Derry. In later years he practised as a physician abroad. At the present day, in addition to Mr. Bridges, we can boast of another scholarly poet, Dr. John Todhunter, a member of our profession, who practised as a physician in Dublin for several years. Mr. Handley adds references to many medical men who gained distinction in science and politics. In travel we have many also of whom to boast.

University Education in London.

MUCH has been written of late respecting the university education of the medical student in London. This was the main theme of the address delivered at Charing Cross Hospital Medical College by Dr. William Hunter, Physician to the Hospital and Dean of its School. The English tradition of the freedom of the hospitals for purposes of clinical instruction is one which has been well described by Mr. Abraham Flexner in his able report upon medical education in Europe. "The medical student in England can really use his material; he has almost as easy access to his patients as the physician has." Here is the keynote to the success of the clinical training in this country as compared with that in Germany. The relations between the university of London and the great teaching hospitals have always been friendly and helpful, and so they have between the hospitals and their medical schools. It will not be disputed that the findings of the Royal Commission on University Medical Education in London with regard to the necessity for grafting on great laboratory institutes to the large teaching hospitals, after the German fashion, are strictly in accordance with the progressive scientific spirit of the age. When a "small compact Faculty of Medicine" has been created for London University which shall not be merely advisory, but made responsible for the educational arrangements and provision, subject to the control of the Senate as regards finance, we may expect to see university medical education in London work out, as Dr. Hunter estimates, to at least £70 to £80 a year per degree student, which is still a good deal less than in a German university.

The Royal Sanitary Institute.

The custom of holding provincial meetings, indulged in by many of the medical societies having metropolitan headquarters, has now become quite an established feature in the programme of these bodies. Apart from annual congresses, which may be held in any large centre, there is much to be said in favour of holding one meeting, at least, in each session in some provincial town. Opportunities are thus afforded for greater interchange of ideas and for country members to take a more active part in the proceedings of the society than they would otherwise be able to do. An attractive programme for the next provincial sessional meeting of the Royal Sanitary Institute, to be held at Newcastle-upon-Tyne on October 17th, has been arranged. Dr. Philip Boobyer will preside at a meeting in the Council Chamber of the Town Hall, at 7.30 p.m., when Prof. J. Hutchens, D.S.O., M.A., M.R.C.S., D.P.H., will open a discussion on "Some Points in the Relationship of Human to Bovine Tuberculosis." Dr. S. J. Clegg will also introduce the subject of "Housing Problems in a Northern Industrial Town." Many prominent local medical men have signified their intention of taking part in these discussions. On the following day a demonstration is to be given of a new electrolytic treatment of industrial lead poisoning, and a series of visits to local works and other places of interest has been arranged for. The local Honorary Secretary of the meeting is Dr. H. Kerr, Medical Officer of Health, Newcastle-upon-Tyne, to whom early notification should be made by intending visitors in order to facilitate proper arrangements.

Damages against a Panel Doctor.

A case of much importance to the medical profession last week came before Judge Thomas, of Liverpool County Court. The parents of a young man, a minor, sought to recover £2 6s. damages from Dr. John Dunlop, of Anfield, for failure or refusal to attend their son after having accepted him as a panel patient. Several messages were sent during the day, and as the doctor did not attend, the lad's father called in another medical man, who found him suffering from pneumonia. Counsel for defendant urged that as the contract for medical attendance was made with the Insurance Committee any action for neglect must be brought against the Committee and not against the medical men who were employed by the Committee. His Honour found against the defendant, both upon the legal points and upon the facts, and expressed an opinion that the defendant was actuated by temper. He gave judgment for the plaintiff, with costs, and allowed an appeal. A brief report of the case will be found in the news columns elsewhere in our present issue. The case will in all probability go to appeal, so that further comment must be deferred for the present.

PERSONAL.

Dr. T. Hood has been appointed Principal Medical Officer of Southern Nigeria.

Dr. Preston King has been chosen Mayor for the ensuing year by the Bath City Council.

Dr. F. M. Sandwith will preside at the annual dinner of the London School of Tropical Medicine, to be held at Prince's Restaurant on Friday, October 24th.

Sir David Ferrier, F.R.S., M.D., will deliver the Presidential Address at the first meeting of the session of the Medical Society of London on Monday, October 13th, at 8.30 p.m.

A monument in honour of Dr. Frederick Bode, who was one of the first to recognise the medicinal properties of the Nauheim waters, was recently unveiled at Bad-Nauheim by the Kurdirecteur.

Col. B. M. Skinner, A.M.S., will deliver the Presidential Address before the United Services Medical Society, Royal Army Medical College, Grosvenor Road, S.W., on October 9th, at 5 p.m.

Among the 218 lecturers who addressed large audiences on Monday evening last to inaugurate a reorganised evening educational system under the London County Council were Sir Victor Horsley and Dr. Robert Jones.

Dr. Edward James Nix, M.D., of Weymouth Street, Portland Place, W., Physician to the All Saints' Children's Hospital, Margaret Street, and to the St. Elizabeth Home for Incurables, Mortimer Street, left estate of which the net personalty has been sworn at £23,032.

Dr. Hideyo Noguchi, of the Rockefeller Institute for Medical Research, will give a demonstration of pure cultures of spirochætes and of his recent researches upon the virus of rabies at a meeting of the Royal Society of Medicine, to be held on Monday, October 13th, at 5.30 p.m.

Mr. G. A. Berry, P.R.C.S.Edin., will deliver the opening lecture of the winter session at the Royal Eye Hospital, Southwark, on Monday, October 13th, at 4.30 p.m., on "The Causes and Symptomatology of Impaired Retinal Activity." All medical practitioners and students are invited.

The following medical men have been appointed as Medical Referees in London by the London Insurance Committee for a period ending Christmas, 1913:—West District: Arthur Stanley Woodwark, M.D., B.S.Lond., M.R.C.S.Eng., L.R.C.P.Lond. North District: John Herbert Burroughs, M.R.C.S.Eng., L.R.C.P.Lond. East District: John Fletcher Porter, M.B.Lond., L.S.A. South-East District: Hugh Davies, M.B., B.S.Lond., F.R.C.S.Eng., L.R.C.P. London. South District: Eric Bayley, M.D., B.S. Lond., F.R.C.S.Eng. South-West Distrist: Reginald Crosse, B.A.Cantab., M.R.C.S.Eng., L.R.C.P.Lond.

CLINICAL LECTURE

ON

A PRACTICAL CONSIDERATION OF VACCINE THERAPY. (*a*)

By WYATT WINGRAVE, M.D.,

Pathologist and Dean to the Central London Throat and Ear Hospital, and Resident Pathologist at the Polyclinic.

Gentlemen,—I want to-day to review a few points in regard to vaccine work, as there are some practical aspects which we can profitably discuss, and which have an important bearing. I do not propose to enter into much detail, but rather to give you the chief items shorn of technicalities which you will find useful in considering the therapeutic aspect.

First of all, what is a vaccine? There is vaccine therapy, and serum therapy. In vaccine therapy we have the introduction of a substance into the body which we call an "antigen," that is to say, a something which has the power of generating in the body an anti-substance, which confers immunity. There are substances in the blood itself which do this, and these we speak of as *natural* antigens, in contradistinction to the immunity which we create by injecting a substance which confers *artificial* immunisation. These antigens when injected into the blood give rise to the production of opsonins.

A micro-organism presents two varieties of poisons: endo-toxins, which are inside the bacillus, and exo-toxins, which are outside. A sharp distinction must be drawn between those two. The best example of an exo-toxin is diphtheria. There are relatively few bacteria which are of this kind. Most bacteria are endo-toxic. We have a natural immunity to diphtheria, but it is very feeble; therefore we turn to one of the lower animals which possesses a high immunity, such as the horse. We increase that horse's immunity by giving him more diphtheria bacilli, and so bring it up to a very high standard. And when we have reached a certain standard, which we test by injecting a guinea-pig with a given quantity of the toxin of horse serum, we find that we establish a unit, and that is the basis of the anti-toxin. We do not deal with the bacteria at all in this case. You could not kill the diphtheria bacilli without killing the patient first. Fortunately, the diphtheria symptoms do not last for long. Bacilli produce in the patient a large amount of poison, and then seem to disappear; but they do not disappear; that is the point. Though the symptoms may disappear, the bacillus may remain for a long time locked up, and may go on multiplying in the accessory sinuses of the nose without causing symptoms. That is difficult to explain. Some say it is because the bacillus becomes so attenuated by subsequent growth that it produces very little exo-toxin. In typhoid, also, the patient may be a typhoid carrier a long time after he has ceased to show symptoms of the disease.

That is serum treatment. But to-day we have to consider treatment by means of vaccines. Vaccines are directed particularly towards the endo-toxins, which are very closely locked up in the bacillus. You may ask how then is it that we get symptoms? For the simple reason that every micro-organism possesses what is called an autolysin, which liberates some of the endo-toxin. But the amount of endo-toxin liberated is very small. In pyogenic infections we have an enormous number of bacteria compared with the small number at work in diphtheria. Yet sometimes a small number of bacilli will produce a given symptom. Let us take a case of ordinary staphylococcal infection. In an ordinary case there may not be much constitutional disturbance; but you may have a case in which disturbance is enormous; it may kill the patient in two or three days. This suggests that there are different varieties of staphylococci; in fact, there are as many varieties as there are of potatoes or pears, and that they vary in their virulence. One form may kill the patient in two or three days; another variety may not kill, and the patient may be subject to that infection for months, or even years (*e.g.*, furunculosis). You cannot demonstrate the difference morphologically or by culture, because in cultures we recognise only three varieties—aureus, albus, and citreus. They vary enormously, and therein lies the essential difference between auto-vaccines and hetero-vaccines. The vaccine is the "hair of the dog that bit you," and no other hair, nor any other dog's hair. We are really reverting to what the lower animals have always practised. Take the case of the dog licking his sores; he is practically giving himself an auto-vaccine, and a very good one too. He is licking up the bacteria from his wound and killing them by probably the acidity of his stomach; the endo-toxins are liberated in his stomach and bowels, they are absorbed by the blood, and then set up an immunity. Such in the dog is a perfect example of auto-vaccine, in contradistinction to a hetero-vaccine. Of what use would it be for that dog to lick the sore of some other dog? None; it is its own bacteria it wants, and it is its own endo-toxin which does good. This endo-toxin can only be liberated when the organism has been killed. So in dealing with a vaccine, our first duty is to demonstrate the presence of an organism in the discharge or in the pus. You try to identify it tinctorially and morphologically, and next you grow it, and, we will suppose, you have produced a good crop of bacteria with their endo-toxins. If you were to make a glycerine extract of the living organism, and inject it into the patient, all that would happen would be, probably, a distinct elevation of temperature, but nothing more than temperature. So what you have obtained is a substance which we call *pyrogen*, a temperature-producer. But if you kill the organism, you get another thing altogether, which is an antigen. The theory has recently been evolved that the pyrogen part is produced in and remains in the medium in which the organism grows. If that were the case, you would expect that if you took the growth from the broth and used the broth, you would have your pyrogen as well as the antigen. But as a fact you do not. I have been testing it very carefully, and I find that the organisms grown in broth do not contain any more pyrogen than those grown on agar or any solid medium.

(*a*) Lecture delivered at the London Medical Graduates' College and Polyclinic on June 27th, 1913.

So when the bacillus is killed and you have made your emulsion, you are now going to inject a distinct substance, an antigen, for the production of an anti-body, and a pyrogen which produces temperature. I am inclined to think that this pyrogen is neutralised in the very act of making the vaccine; because we heat it up to 60° C., and by doing so, it is likely the pyrogen is got rid of. So we have now only to deal with the antigen. Having grown the organism, you now treat it with some normal saline solution. Stir it with a platinum loop and make an emulsion, when it becomes opaque. Under the microscope you can now see what it consists of. We are not going to trouble ourselves about isolating: we do not want to isolate. When vaccine therapy was first introduced, an immense amount of time was wasted in isolating bacteria. If you subculture and separate bacteria, you attenuate them, so that your last culture is probably a characteristic organism under the microscope, but it has lost all its power. So what you grow is made into a vaccine, though one of the varieties of organism is probably more important than the others, and it is that important one which you go for. You have killed them all, and consequently you are doing no harm by injecting their products; but by injecting you are bound to get the right one. Greater precision would be shown by separating them and injecting them, and taking opsonin observations for each; but what a long time that takes; it is a fearful task, and before you have done that the patient is either dead or cured. Having obtained the emulsion, your next duty is to find out how strong it is: in other words, you want to standardise it. That is very simple, for you find a very good standard in blood. Blood contains five million red corpuscles to the c.mm.; consequently you take one drop of blood, one drop of this emulsion, and one drop of citrate, mix them and count; and you know if you have five million red cells and five million bacteria in the film it is the same strength, and you know what dilution is required. If you wish to give 500, it is simply a question of a sum. I prefer to use, in diluting, tricresol and normal saline. Formerly carbolic acid was used, but that is undoubtedly toxic, and some people do not stand it; the smallest quantity in some people causes carboluria, and moreover, carbolic acid has been shown to have a distinct influence on the endo-toxin. Moreover, tricresol is about the best antiseptic you can possibly use. It is oily and will not mix with water, and so I make a 10 per cent. solution in alcohol and keep it as stock. This is diluted ten times to make it one per cent. It is one of the best mixtures you can have for sterilising skin and instruments, for it has a wonderful power of killing bacteria without precipitating proteids and without destroying the very things we want to save. Then you sterilise it, and this should never be done at a higher temperature than 60° C.; otherwise you will destroy the very substances you want to keep, the antigen. That is done for half an hour, and it suffices for nine-tenths of the bacteria. But sometimes we come across sporing bacteria, and you know how difficult it is to kill spores. So you examine most carefully under the microscope to see if any are present. If you find any suspicion of sporers you must sterilise a second and even a third time, with 24 hours intervals. If there are sporers, at least three days longer will be required for the preparation of the vaccine. Then 1 c.c. is put into a capsule, sealed, and then put into the steriliser for 15 minutes at 55° C. The vaccine is now made.

You will forgive me if I say a few words as to how it should be used. Your syringe should always be kept in tricresol one per cent. Your needles, if they are steel, or even more expensive ones, should be kept in paraffin. Before using the needle, heat it in the flame to make liquid any paraffin remaining in it, and expel it. Then see if your syringe is working. Always shake the capsule well before you start, because bacteria settle at the bottom. Then file a little nick in the neck, break off and charge the syringe, but do not drag out the piston, otherwise you will get air bubbles in; but remove it gradually by twisting. But there are always bacteria, especially staphylococci, lurking in the skin, consequently you may easily introduce a few of these. You should take some strong tricresol 10 per cent. on a piece of cotton wool and rub the skin with it. That will kill a large number, though it will not kill all. You cannot thoroughly sterilise the skin, do what you will. You may even try the modern iodine method.

Now let me consider with you some details in regard to suppuration. It is a story which cannot be related too often, because it tells us the inwardness of our work. Certain bacteria are introduced into the tissues, but remember, suppuration can be brought about without bacteria; chemical agents, such as biniodide of mercury will produce it; so will heat, and indeed anything which will produce fresh leucocyte activity. Suppose we are dealing with an infection causing suppuration. As soon as bacteria enter, our policemen, the leucocytes, are set free. The leucocytes are poured into the abscess cavity, and eat up the bacteria. But after a time, if you were to examine the pus, you would not find so many phagocytes as in the early stage; moreover, each will contain fewer bacteria. Later still, the leucocyte will be practically empty. Why? For this simple reason. The micro-organism produces what is called a leucocydine, which acts upon the leucocyte and paralyses it, so that it can no longer eat up the bacteria; and by and by the leucocyte is not only paralysed but is killed and becomes granular and is broken up, and when it is broken up it is a true pus cell. What does it contain? A most important substance, trypsin. It is most potent, because it has power to dissolve living tissue as well as dead; it will dissolve bone, muscle, ligament, cartilage, as readily as soft tissue. That is how an abscess cavity is made. The extension of the pus is not by pressure only, but by actual solution of the living material. So we have got an enormous number of bacteria, a large number of dead leucocytes, some living leucocytes, and an enormous quantity of toxins from the bacilli, with trypsin from the leucocytes. These get absorbed, so that eventually there is toxæmia. But if the pus is allowed to remain there, sooner or later you get bacteria in the blood, causing a true pyæmia. Hence, the moment we recognise pus, we let it out. We do so first to get rid of as many bacteria and their toxins as possible, and secondly, for the purpose of removing the trypsin, and so preventing any further extension of the cavity. You know how red the skin gets round the orifice of a fistula or a sinus. That is because the trypsin from the dead leucocytes is acting as an irritant of the epidermis and as a solvent; so that it is best to put a little vaseline on the edge of a sinus to protect it from the discharge. You know a running from the nose due to a cold will set up a distinct erythema of the skin, and that even little papules will form. Having got rid of the substances I have named from the abscess cavity, we have a chance of doing some good. We inject vaccine. What is the result? Probably this abscess or suppurating focus still goes on. You want something to help the vaccine; there is what Wright calls "a choked filter," *i.e.*, the barrier between the blood and the abscess cavity is blocked by dead tissue, coagulated fibrin, and such like. You can unchoke that filter in two ways. First, you can do it by Bier's mechanical method of decompression, exerting a *minus* pressure on the part If it be a carbuncle, apply a cupping-glass and suck out the air until blood actually appears on the surface. Or you may syringe out the cavity, or introduce into it gauze saturated with a weak citrate solution. This consists of sodium citrate one per cent., sodium chloride about two per cent. The citrate dissolves the coagulated blood and lymph, and the sodium chloride sets up an exosmosis, consequently the leucocytes and the serum can readily pass through that choked filter and get at the bacteria in the suppurating focus. So by negative pressure you are helping the flow of blood to the part, and you have an osmotic flow outwards towards the infecting point.

What do we mean by an opsonin? What have we injected? We have injected what is practically a soup; we have made a broth of the killed bacteria, which is valuable to us for the endo-toxin it contains. We inject this antigen into the blood; it does nothing of itself, but it gives rise to the production in the body somewhere or other, probably in the lymphatics, of an opsonin. There are two views with regard to the action of opsonin. One is that the opsonin renders the bacillus more tasty to the leucocytes; the other that it does not act on the bacillus so much as on the leucocytes; it is a stimulant to the leucocyte, and acts on it like a tonic. Probably the real position is midway between the two. What happens is this: we give an additional quantity of immune substance to the person, and this renders the bacteria more readily eaten up by the leucocytes, and partly acts on the leucocyte itself. The immune substance is not in the leucocyte, it is in the serum. Wright's theory tells us that the leucocyte is an indifferent quantity; that the leucocyte is of little importance beyond the fact that it is a scavenger, and that we must look for our protection to the substance in the serum, which acts on the bacillus only. It is like two men sitting down to lunch, one being very hungry, and the other not. The hungry man wolfs up his chop quickly, but the other calls for some sauce, for he cannot eat his chop until it has been well sauced. Our leucocyte cannot eat the bacillus until it has been well sauced, and our opsonin acts the part of the sauce. Whatever view we take, we are bound to admit this: that the outcome of injecting the antigen is the production of a new substance which is something in the nature of an opsonin, which turns the bacillus in such a way as to make it digestible. It is digested and taken up by the leucocyte and rendered harmless. Immunity varies considerably. It may last only a few days, or it may last a lifetime. Probably it is kept going by the presence of the organisms themselves. This is well shown in the pathologist who in spite of perhaps daily infection is none the worse for it, but after his autumn holiday immunity is lost, and the slightest infection causes trouble until immunity is recovered in the course of his work.

Now a few words about the difference between vaccines for acute cases and vaccines for chronic cases. In acute cases you must deal with the case a little differently from chronic. Fairly big doses should be used and given fairly often. But in chronic cases you give moderate doses, and at fairly long intervals. The first dose of a vaccine should be half the maximum strength. The second dose, on the third day, should be full strength, and that should be repeated every eighth day. As the patient begins to feel a little better, you may want to give more. Do not give a bigger dose, but simply diminish the interval between doses. But in acute conditions, as those of gonorrhœa and pneumonia, you may gradually increase the dose. Working from stock vaccines, you have capsules of different strengths. Begin with 50 million, then go to 75 million, then 100 million, 150 million. But that is not so easily done in auto-vaccine work. It is made up of one strength, and you vary it by varying the interval, not the actual dose.

I will now refer to anaphylaxis. When you inject the first dose, there may be no signs; you inject a second dose, and probably there is a flare-up, but not a severe one. You inject a third dose, and there is a terrific flare-up; indeed the patient is so intolerant of what you have injected that you may hesitate about giving another dose. But give him his fourth dose, and the alarming symptoms may subside. This flare-up on the second or the third day is simply due to the rapid accumulation of the immune substance; in other words, the antigen which you have given has not had time to manufacture a full amount of opsonin. But you need not fear anaphylaxis, because when dead bacteria are injected, the pyrogen has been got rid of, and there is insufficient to cause a high temperature. Some bacteria possess more pyrogen than others.

In this Polyclinic we cover a wide field. In the last few weeks I have had several very good illustrations of vaccine for hay fever. There is a great deal of hay fever on paper, but very little in actual experience; when one meets with supposed hay fever, there is generally found something to account for it, and the case is found to be innocent of hay pollen. These cases are found in parts of the country or world where hay does not even exist. You will generally find there is some irritability of the optic nerve; a man says he cannot play a round of golf in the glare of the sun, or cannot tolerate the presence of chalk cliffs, and he attributes it to hay fever. Give him a pair of blue glasses, and his photophobia will disappear. Or take another case. The discharge is very profuse. On examining it, you probably find a number of oxyphyle cells. You say it is hay fever. Examine for bacteria, and you may find plenty, perhaps two or three varieties, but no hay pollen. The patient's accessory sinuses are probably excellent culture tubes, and the scavenging leucocytes are not turned out in sufficient numbers to deal with them. But capture the bacteria, make a vaccine and inject it, the leucocytes at once begin to do their work, and an artificial immunity is soon produced sufficient to get rid of the immediate attack. Sometimes no second course is needed, but two are generally all that are necessary. There is a form of trouble supposed to be hay fever in which there are no bacteria, but in the free discharge from the nose there are a number of cells. You will nearly always find sugar in this flow. It is a leakage of fluid from the cranial cavity, the overflow of subarachnoid fluid passing down the nose, over the olfactory nerve, and into the nose. It is a safety valve, and does no harm. It varies with the arterial tension, and if you give a mild course of mercury, or effervescing sodium phosphate, you will generally reduce the arterial pressure, and with the addition of ammonium bromide the whole condition will disappear. But if you start local analgesia, such as the application of cocaine, atropine, and morphine, you set up a vicious circle, and the more the patient has, the more he wants. The most common group is that in which the nasal flow is the result of some local condition, such as an enlarged turbinal, or a spur, or the distension of a sinus. But in some few cases the patient is firmly convinced, in spite of all you say, that the pollen is responsible for his trouble, so he has a "specific" injected, and he promptly gets well, or not.

The opsonic index, so far as its practical application is concerned, is seldom used, because it is very tedious, although it is extremely valuable. Instead of it you can take the phagocyte index, which is very simply and easily done, and very reliable. You have an emulsion of bacteria, and a solution of sodium citrate. Puncture the patient's thumb. You have a certain distance marked out on your pipette, up to which a certain quantity of citrate solution is sucked, then a given quantity of blood, then a given quantity of bacteria, and blow them on to the slide; mix and return to pipette, seal, and then incubate for 15 minutes. Take off the cap, break off the end, and blow the mixture on to a slide and make a film. Stain by thionin or James's solution, and count. You do the same with your own blood for comparison. So it is simply comparing the phagocyte hunger of the patient with your own. The opsonic index is complicated, and rests upon the testing of the serum only. No two observers give exactly the same figure; it is necessary to take a number of observations, and get the average.

The diseases for which I have prepared vaccines at the Polyclinic cover a very wide range, and the results obtained are most gratifying, especially in cases of chronic arthritis, nasal pharyngeal catarrh with sinusitis, chronic bronchitis and bacteriuria. I am preparing an analysis which will be published shortly in the Polyclinic Journal.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal, The lecture for next week will be by Professor Leon Berard, Surgeon to the Hotel Dieu, Lyons. Subject: "The Treatment of Fractures of the Skull by Lumbar Puncture and Early Trephining."*

ORIGINAL PAPERS.

A GENERAL VIEW OF MALINGERING. (a)

By F. S. PALMER, M.D., F.R.C.P.Lond.

Physician to the West-End Hospital for Diseases of the Nervous System.

The term malingering, derived from the French adjective *malingre*—weakly or sickly—had acquired a special significance and much wider application. The present-day interpretation of the word included the *suppressio veri*, as well as the *suggestio falsi*, and the reason probably was, that there was no essential difference between the simulation of disease to extort money from an employer, and the deliberate concealment of known ill-health to defraud a company or corporation. Formerly it was chiefly encountered in the Army and Navy, among prisoners, and the inmates of hospitals and workhouses, but recently it had become more general, particularly among industrial workers. Anyone who wilfully feigned, induced or protracted an illness or disability to avoid work or punishment, or deliberately concealed the existence of a disease, of which he had certain knowledge, to gain some desired end, was a malingerer. Among the influences which promoted malingering was the trend of modern legislation. Since the Workmen's Compensation Act of 1906 came into operation the number of claims had gone up by leaps and bounds, and precisely the same experience was reported from France and Germany, where the accident laws were older than our own. Employers had discovered that it was cheaper to settle claims out of Court than to contest them. Allegations had been made that medical certificates were too loosely given, but since the members of the Friendly Societies had been informed that the State pays, the sharp look-out for malingering was no longer maintained. Although the activities of some speculative lawyers and so-called Legal Aid Societies stirred up strife between employers and employees and encouraged malingering, it was a great mistake to suppose that the enormous increase of claims admitted by most of the approved societies was due entirely to malingering. It was true only to a limited extent. The National Insurance Act had opened a new and perilous chapter in history and unlocked the floodgates to the risk of malingering on a scale hitherto unknown, which would be felt more on the medical than on the surgical side of the profession. The inclusion of women into the scheme, and the relaxation of the rule of medical examination had admitted a number of sickly and delicate persons who were a constant drain on the funds. Six months' working of the Act had shown that the sickness claims of women were amazing. People who had been promised a liberal exchange for their contributions were not likely to overlook the obligations on the other side of the bargain, as the desire to get something back for what had been paid was a human failing. The logical sequence to compulsion was resistance, and that it would take the form of malingering in many instances was a certainty. The psychology of malingering was a complex and interesting study. Pecuniary gain was not always the underlying motive, but often other influences were at work—such as idleness, sympathy, notoriety and resentment. When a workman or other person is well, or it may be better, provided for during sickness, the tendency to delay the return to work was only human. Hitherto the largest proportion of claims were for the results of accident or injury, and the extravagant damages demanded from wealthy employers, corporations or the State were often astonishing. The elasticity of conscience where railway companies were concerned was proverbial. Many persons fit to return to work were restrained from making the attempt, when litigation was in the air, by the fear that it might prejudice the issue. Introspection, suggestion, repeated medical examinations and consultations with solicitors, according to the psychological law led to the intensification of symptoms, and so long as these mischievous agencies continued in operation the abnormal mental condition was not likely to improve. Although it was the duty of the profession to discountenance any kind of fraud which came under notice, no doctor was expected to undertake the duties of a detective. If he acted in good faith not much was to be feared, and no sensible medical man would make an accusation of malingering unless he was prepared to bring forward positive evidence in support of the charge. His reputation and existence were at stake, and little mercy would be shown him for a mistake. Precipitate action was to be condemned. In doubtful cases it was far better to be deceived than allow unjust suspicion to fall on the victims of some obscure or depressing disease. The odium of an accusation of malingering should rest with some independent person to whom the case was referred, and not with the practitioner.

(a) Presidential Address delivered at the opening of the West London Medico-Chirurgical Society, October 3rd, 1913.

The essential feature of malingering was deliberate deceit to gain some desired end. Valetudinarianism occupied a different position and would be dealt with separately. The methods of malingering were difficult to group, and Dr. Palmer considered them under the following heads: (1) Personation was very rare in this country and entailed great risks. If detected it speedily brought the offender within the meshes of the Criminal law. (2) Simulation was exceptional, the word was often misused, it meant an imitation or sham. To counterfeit the symptoms of organic disease successfully required a high order of intelligence, combined with remarkable powers of memory and attention. Few, if any, doctors could be found to coach the performer. It was always overdone. Hysteria imitated disease better than any simulator. The type of disease usually selected was some functional disease of the nervous system, since it could be more easily feigned, required no special knowledge, and was less likely to be detected. (3) Substitution of origin, date or material was quite common. Attempts were frequently made to attribute the symptoms of pre-existing organic disease to recent shock or traumatism; specimens of urine were often substituted and several examples illustrating this form of deception were quoted. (4) Exaggeration of symptoms was a very popular form of malingering. When obviously magnified detection was comparatively easy, but in the minor degrees it was more difficult. Valuable help was often obtained from careful observation of the appearance, attitude and behaviour of the examinee. There was much to be said in favour of the German plan of compulsory hospital detention in doubtful cases. (5) Concealment of disease was not always fraudulent, but when adopted for the purpose of imposing on life assurance or other companies it assumed a very serious aspect. (6) Hunger striking was a despicable form of malingering when practised to escape punishment for misdeeds. If criminals who resorted to such means were sane, there were no reasons (except political or sentimental) why the law should not take its ordinary course, without distinction in their favour.

Valetudinarianism was of great importance from the medical standpoint. Many of these cases, no doubt, came under the head of unconscious or subconscious malingering, but it also included a considerable proportion of genuine invalids who demanded our utmost sympathy and protection. How were they to be distinguished? Surgical cases gave far less trouble than medical ones. There was not much scope for fraud in visible physical injuries. The surgeon sees and the physician is often in the dark. When objective signs were present they could be deciphered on regular lines, but if the complaints were only subjective one had to rely on the none too reliable statements of the claimants. Some of the so-called functional cases deceived the very elect. Insanity was more frequently feigned by criminals, or persons of the better class charged with theft, or offences against morality; epilepsy by mendicants to deceive the charitable. Hysteria and neurasthenia, with their combinations, presented special attractions to the dishonest. Hysteria was a psychical disorder revealing itself by certain stigmata, mainly objective, which could be tested. In neurasthenia there was no antecedent condition except in neuropaths. The symptoms were mostly, if not entirely, subjective, but none the less real and distressing to the victim. Small wonder, then, that neurasthenic disturbances were the favourite complaints of impostors. They had little to learn, and their statements were difficult to disprove. In all such cases, however, there was ever present the possibility of some underlying organic cause. Before a diagnosis of functional disease could be made organic signs must be eliminated from the field of inquiry. Experience had convinced the speaker that the sufferings of the true neurasthenics were only too sad and genuine, and the sooner this fact was recognised outside the medical profession the better. To brand them with the ugly name of malingerer was both cruel and unjust. Finally he dealt with the prevention of malingering, and made the following suggestions for the arrest of the growth and extension of this serious evil. (1) The appointment of medical referees of wide experience who should be independent—specialists in their particular departments of medicine and surgery. (2) That medical assessors should sit with the arbitrators or County Court judges to interpret medical evidence. (3) A system of organised lay inspection to visit houses and ascertain facts. (4) Compulsory detention in hospital of doubtful cases. (5) A time limit to functional illnesses. (6) Periodical medical examination of suspected cases by independent practitioners. (7) Some system of registration by which the benefits of claimants from all sources could be made known.

FURTHER INVESTIGATIONS UPON ACUTE RHEUMATISM. (a)

By F. J. POYNTON, M.D.,

AND

ALEXANDER PAINE, M.D.

At the International Congress held in Madrid in 1903 we demonstrated our reasons for the statement that we had made in 1900 that acute rheumatism was the result of an infection by a diplococcus of the streptococcal group, which we placed between the pneumococcal and septic streptococcal infections. Since that date we have been engaged in supporting our statement by additional evidence, and in following out the logical conclusions of such an assertion by a study of the influence of variations in the virulence, dosage and duration of the infective processes in man and animals, and an investigation of the various organs that may be attacked. Our evidence based in 1903 upon some 30 cases now rests upon the investigation of nearly 100, and our view as to the causation of the disease has in no way changed.

The problems that arise from a study of the variations in virulence and duration of the infection are, we believe, of the greatest importance in practical medicine. Thus, for example, what will be the result of a persistent and virulent rheumatic infection of a cardiac valve? In answer we would say that we have been led by experiment and clinical investigation to make this further statement, that this diplococcus is a cause of malignant endocarditis, or in other words, that rheumatism may be a cause of this deadly disease. Further, that at the bedside every gradation from simple to malignant endocarditis may be detected.

(a) Paper read before the Section of Medicine, International Medical Congress, 1913.

The connecting link between simple and malignant endocarditis most easily recognised is the very important combined aortic and mitral rheumatic endocarditis which occurs so frequently in children and adolescents. This combined lesion is one which, in our opinion, not infrequently foreshadows a malignant tendency in the rheumatic process, and is later in life particularly liable to develop into the true malignant rheumatic type. The damage to the two valves may occur during the same illness, or the aortic valve which is usually involved the later may be attacked in a recrudescence, or lastly, in a second attack of rheumatism.

Our reasons for the statement that we believe there is a rheumatic malignant endocarditis are the following:

1. Clinical investigation supports this view.
2. The minute examination of the morbid anatomy in man and animals also supports this view.
3. A diplococcus, identical so far as we are able to ascertain to the "diplococcus rheumaticus," isolated from the simple endocarditis can be also isolated from vegetations of the malignant type.
4. This diplococcus may, in animals, produce on intravenous inoculation, either simple or malignant endocarditis, or transitional types, or a carditis, or the entire picture of acute rheumatism.
5. It may produce in the same animal an acute rheumatism which is recovered from, and on reinfection a malignant endocarditis.

We show specimens and drawings in support of these statements.

This is one point to which we have devoted much attention. Another is to the study of non-suppurative arthritis.

By experimental investigation we have proved that this diplococcus which usually causes a transitory polyarthritis may also produce the following results.

A severe and chronic periarticular arthritis, a monarticular osteoarthritis, a destructive non-suppurative arthritis with guttering, dislocation, erosion of bone, lipping, ulceration, and fibrillation of cartilage, and profound muscular atrophy. Not only have these results followed, but periosteal nodes, precisely similar to those seen in severe rheumatoid arthritis in man, may result from this infection.

We would repeat that the arthritis is non-suppurative, and add that the exudation may be actually sterile.

So far, then, as the arthritis is concerned, it is apparent to us that the infective agent of acute rheumatism may produce all the lesions which have been claimed to occur in those forms of arthritis included under the vague term "rheumatoid arthritis."

We do not pretend for one moment that acute rheumatism is the only cause of rheumatoid arthritis, for that would be most unjustifiable, but we do believe that these investigations throw considerable light upon the pathology of non-suppurative arthritis. The difficulty there may be in animals of isolating the infective agent from the joints which we know from the certain facts of experiment are attacked by an infection, throws interesting light upon the acknowledged difficulty there is in the discovery of the infective agent in the chronic non-suppurative human arthritis. The explanation lies in the great power the synovial tissues possess for destroying the diplococci and other micro-organisms, together with the fact that it is in these tissues that they are chiefly located.

We illustrate the statements that we have made by our specimens and drawings.

Another condition we have investigated further is rheumatic chorea, and in addition an example of rheumatic hyperpyrexia.

In the examination of the morbid anatomy of chorea, we had the help of Dr. Gordon Holmes, and the results we obtained may be summarised as follows:

1. We have found the diplococcus in the pia mater and brain in the cases of fatal chorea.
2. In the pia mater it produces perivascular exudation and the condition now recognised under the term "submiliary nodules."
3. In the brain it causes perivascular changes of the same order, with minute thrombosis and consequent foci of softening and also sometimes minute hæmorrhages.
4. The brain-cells show widespread chromatolysis. The axones are but slightly damaged, but degeneration of some of them can be detected by the usual methods.

The result of our examination of the case of rheumatic hyperpyrexia was to strengthen the view that it was a result of a virulent toxæmia rather than an overwhelming invasion of the tissues of the brain by the diplococci.

These facts are illustrated by these figures taken from the microscopical preparations shown at the various societies.

Another point to which we have directed particular attention has been the condition of the tonsils in the rheumatic. Our investigations have led us to these conclusions, that one certain path of infection is from the inflamed tonsils, and that the chronically enlarged and diseased tonsils so often met with in the rheumatic may also harbour the infective agent, and the attacks of sore throat may then prove a continual menace to them by permitting reinfection of a greater or lesser degree of severity.

The evidence rests upon the isolation by plate culture of the diplococcus from these organs, and the reproduction of the disease by intravenous inoculation into animals.

Our most recent investigations have been concerned with the possibility of throwing lights upon any part that the rheumatic infection may take in producing abdominal affections.

For more than ten years we have recognised a mucous colitis in rabbits as a result of this infection, and also intussusception. We have also isolated the diplococcus from the bile of rabbits infected intravenously with the diplococcus and have observed the occurrence of a considerable gallstone.

In 1911, however, we produced appendicitis by intravenous inoculation of the diplococcus isolated from the knee-joint of a boy suffering from a moderate attack of acute rheumatism. This occurred in young rabbits of six weeks, four out of twenty inoculated suffering from appendicitis, nineteen from polyarthritis, and one from pericarditis.

In 1912 we isolated a strepto-diplococcus from a child suffering from follicular tonsillitis and acute appendicitis. It was obtained both from the tonsils and the exudation of the inflamed appendix, and with it we produced appendicitis in young rabbits, and also polyarthritis, and in one instance endocarditis.

These results are not sufficiently numerous as yet to allow us to say more than that they are suggestive of the possible existence of a rheumatic appendicitis, which, since Kelynack's original paper some twenty years ago, has been held by various physicians to occur in man.

They also, however, appear to us to throw fresh light upon the pathology of that most important disease, appendicitis, and direct attention to the probable importance of a blood infection, as opposed to a local cause as the exciting factor. The writings of Kretz and other German observers since Kelynack first suggested the connection have directed attention to the relation of appendicitis to tonsillitis, and these investigations seem to fill in a link in the chain of evidence.

During the last six months our investigations of the morbid anatomy of the human diseased appendix when compared with that of the animal entirely support the view that the process arises by a blood infection.

We illustrate these points also by our specimens and drawings.

The fact that intravenous inoculation of the diplococcus may produce a solitary ulcer in the appendix is of interest also in its bearing upon the pathology of solitary ulcer occurring at any point in the intestinal canal in man, and since arthrites associated with abdominal symptoms may result from intravenous inoculation of the diplococcus it does not necessarily follow that the arthrite is the outcome of auto-intoxication from the bowel.

In conclusion we would venture to emphasise that these investigations upon acute rheumatism encourage us to direct great attention to the possibilities of the prevention of this disease, which, among other injuries it does to the human frame, is the first cause of organic heart disease in childhood.

ON THE TREATMENT OF SKIN AFFECTIONS BY SOLID CARBON DIOXIDE. (*a*)

By J. L. BUNCH, M.D., D.Sc., M.R.C.P., B.S.

Physician for Diseases of the Skin to the Queen's Hospital for Children, London; Physician to the Skin Hospital, Leicester Square; Membre Correspondant de la Société Française de Dermatologie.

At the meeting of the British Medical Association last year I read a paper on two thousand nævi, which I had treated by the application of solid carbon dioxide, quite aside from other methods of treatment, and I have treated a large number of nævi since. Apart from the rapidity and comparative painlessness of the method, one great advantage is the ability to cut or mould the stick of snow to any shape, so that a nævus of reasonable size, whatever its irregularity of outline, can be accurately frozen in its whole surface at a single application, a result which cannot, of course, be obtained by such methods as electrolysis, the cautery, or radium. A single application is usually sufficient to cure a stellate nævus or small angioma, if care is taken to shape the stick of snow accurately to fit, including a margin of healthy skin of one to two millimetres all round, and exercising firm pressure on the skin. Pigmentary nævi, especially if they are hairy, usually need more than one application, and it is much better to do too little at one sitting than too much, as I have seen quite unsightly scars, sometimes keloidal, produced by a too prolonged application of the snow to moles, the scar being often to all intents and purposes as disfiguring as the original skin lesion. When the hairs on the mole are coarse, I prefer to remove them by electrolysis, and the subsequent return of any pigment in the nævus can be obviated by giving radium applications while the skin is healing up from the carbon snow treatment.

In the case of nævo-fibromata and nævo-lipomata, where excision is objected to, a great deal of the disfigurement can be removed by treating the purplish skin areas with carbon dioxide until the surface is white, and then inserting some electrolysis needles, insulated with shellac to within half an inch, or an inch, of the point, right into the swelling, and repeating this procedure if necessary at different points of the swelling.

Port-wine stains (*taches de feu*) are undoubtedly the most unsatisfactory kind of nævus to treat by any method, and one sees cases, the colour of which is so intense, and which involve the deeper structures to such an extent that no method at present at our disposal is capable of doing more than diminish the disfigurement without running the danger of unsightly scarring. The most difficult cases to treat are those in which the corium and underlying structures are deeply involved and which have a nodular, irregular surface, with warty projections, and for these there is no really efficient method of treatment. But for a moderate-sized red, superficial port-wine stain in a child, when the purple tint is absent, or but slightly marked, applications of solid carbon dioxide at intervals of a fortnight or three weeks will often give excellent results. In adults, too, I have been quite successful when the port-wine stain was fairly localised, and carbon snow was employed in conjunction with a plaque of radium of one million activity.

Cases of *linear nævus* and *nævus verrucosus* also do very well when treated with solid carbon dioxide; but for verrucose nævi, where there is much thickening and warty growth, very firm pressure must be made and the pressure maintained for about sixty seconds or even more.

In all these cases I consider that the stick or crayon of solid carbon dioxide is far preferable to any other method of applying carbon snow.

When a much greater intensity of cold is required than that obtainable with solid carbon dioxide, or a large surface has to be covered in the minimum of time, it is often convenient to use liquid air. The temperature of solid carbon dioxide is only −78.2° C., while that of liquid air is −190° C., so that with the latter reagent the freezing is much more rapid.

The application to the skin of either liquid air or solid carbon dioxide for a few seconds causes a preliminary freezing of the tissues, followed by a well-marked inflammatory reaction, which, according to its intensity, may result only in thrombosis of the superficial vessels and fibroplastic sclerosis of the epidermal tissues, or any stage between this and complete necrosis. The action differs from that of the cautery or a caustic in that all the tissue elements frozen are not indiscriminately destroyed, and the resulting scarring is, owing to the gradual transformation

---

(*a*) Abstract of Paper read at the Annual Meeting of the British Medical Association at Brighton, July, 1913.

of the tissue elements into fine fibrous tissue, much more supple and inconspicuous than when these other methods of treatment are employed. Moreover, the exact amount of inflammatory reaction can be controlled, both as regards extent and depth.

Rodent ulcer is perhaps the skin disease, other than nævi, in which solid carbon dioxide gives the best results. Small rodent ulcers on the face can frequently be cured by a single application of forty seconds with firm pressure, and, if care has been taken to go well outside the raised edge of the ulcer, no further application may be necessary, and no recurrence occur. But if the spreading edge be not destroyed in its entirety, and a small portion of the edge be left, this usually gives rise to a recurrence in a few weeks or months. The recurrence is, however, considerably smaller than the original growth, and one or two more applications will complete the cure. When the original ulcer is of the size of half-a-crown, or larger, I usually give an initial application of forty seconds, followed by a second application of thirty seconds at the end of a week. The ulcer is then allowed to heal up under boracic acid dressings, which takes about three weeks, and it is then carefully examined to see whether any traces of the edge still require further treatment. The results thus obtained are, in my opinion, equal to, if not superior to, any result got with X-rays, ionisation or radium, and of course with greater rapidity and less expense.

Lupus erythematosus of the discoid or nodular variety reacts very well indeed to treatment with solid carbon dioxide, and fifteen seconds' applications are usually sufficient. When the patches are old-standing ones, and there is a great deal of thickening, somewhat longer exposures are necessary. A small superficial ulcer results from the freezing, which heals up in a week or two, and the newly-formed tissue is usually sound and supple, with very little appreciable scarring.

I have used this reagent in a number of cases of *Lupus vulgaris*, and, although many of the cases can be cured by it, the scarring is rather excessive if no recurrence is to take place. In small patches the isolated nodules can be more satisfactorily destroyed one by one by other means, and large patches are better treated by scraping thoroughly and immediately X-raying. If, in addition, a successful Thiersch-grafting be performed, the scar will be much better than that got with carbon snow in a really severe case. The latter is, however, preferable to X-raying without scraping, on account of the telangiectases which repeated X-raying is so likely to produce.

Localised patches of *chronic psoriasis, chronic eczema* and *Lichen planus* respond extremely well to freezing. The irritation caused by the lesions of the two latter diseases ceases immediately after the snow has been applied, the patches heal up with healthy skin after a single application as a rule, and even the soreness caused for a time by the snow is far preferable to the itching previously experienced.

Corns and warts lend themselves very well to cure by freezing, but they are such bad conductors that very firm pressure has to be made and the exposure increased to a minute or more. The period of freezing can, however, be appreciably diminished by first shaving down the wart until it is nearly flush with the skin and then applying the stick of solid carbon snow. Corns on the sole of the foot, after adequate freezing, are apt to be rather excessively tender, owing to the resistance of the underlying plantar fascia, and the pressure which it causes on the inflammatory swelling produced by the freezing, but this can be diminished or prevented by injecting a few drops of novocaine soluton.

Chronic ulcers of the leg, when the edge is markedly thickened and indurated, may often be made to take on healthy healing action by being frozen lightly for about twenty seconds. The object here is not of course, as in rodent ulcer, to destroy a malignant growth, but to induce the formation of healthy granulations in place of the indolent ulcer base, which shows little or no tendency to form fresh, actively growing tissue. The actual edge of the ulcer, if much indurated, should have a longer exposure to the snow.

SOME RHENISH SURGERY.

By WILLIAM DOOLIN, M.B., F.R.C.S.I.
University College, Dublin.

For the busy practitioner at home, who wishes to take a short respite from the cares and worries of modern practice, one can recommend no more pleasant no more profitable trip than a "busman's holiday" down the Rhine, combining pleasure and instruction alike

As the University was changed from Cologne to Bonn by the Electors, there is now no big teaching clinic for students in Cologne, but there exists a well-known centre for German post-graduate workers, the Kölner Akademie für Praktische Aerzte, under the direction of Prof. Bardenheur.

Bonn.

The surgical clinic is under the direction of Geheimrat Professor Garré, who, on succeeding August Bier, in 1907, on the latter's call to Berlin (*vice* von Bergmann, deceased), had the whole structure rebuilt, so that as it stands to-day it is a model modern hospital.

I spent two very interesting mornings with Prof. Garré. As is usual in the big German clinics, all clinical instruction is given in the operating theatre, or Hörsaal. The patient's bed is wheeled into the arena, round which a series of seats, in ascending tiers, is arranged in horse-shoe fashion, so as to accommodate about 100 students comfortably. The assistant in whose ward ("station") the patient happens to be, reads out the case-history. The professor then has two or more students called down to the bedside to examine the case, and proceeds to "quiz" them on the diagnosis, treatment, etc., the other students taking notes the meanwhile. In this manner four or five cases are got through in an hour. Ward instruction is not the practice in German clinics, as the classes are too large and unwieldy. (I have seen as many as 200 students at a lecture of Bier's in Berlin.) After lecture, the cases are operated upon.

Garré's aseptic *technique* leaves little to be desired. Hands are washed for ten minutes with nail-brush and sterilised soap in running water, then for five minutes in alcohol sublimate, and finally rinsed in sterilised cold water and dried with a sterilised towel. A sterilised "mantel" with short sleeves is then drawn on over a rubber apron and fixed by a sister. The forearms are covered with sterilised, tight-fitting manchettes, reaching from the wrist to above the elbow. No gloves are used; caps are worn, but not masks. The operation area is painted twice with strong iodine solution. The patient is well covered during the operation. Silk is used almost exclusively as suture and ligature material; Garré uses a very fine, strong silk (.0000), which he gets from Piersol, of London. Catgut is used only exceptionally for muscle suturing in big kidney operations. Professor Garré is particularly interested in kidney work, and has published a standard text-book on the subject, amongst a host of other works. The pathological museum contains some very fine specimens of surgical kidney, hydronephrosis, and kidney abnormalities, all preserved by the Kaiserling-Pick method. The original colours are particularly well preserved.

I watched Garré do several operations. The first patient was a man, æt. 34, suffering from a large cyst—adenomatous goître, with superimposed symptoms of Basedow's syndrome. (By the way, in most of the German clinics I have visited, with the solitary exception of Prof. Bier's, one hears only German names. Graves' disease is known as "die Basedowsche Krankheit," Colles's fracture is called "typische radiusfraktur," and Lane's kink has not been heard of, except by Payr, of Leipzig! Garré believes that exophthalmic goître is a dysthyroidism rather than a hyperthyroidism, as, indeed, is the prevalent consensus of opinion in Germany.

Garré has devised his own operation for these goître cases. He always operates under local anæsthesia. After making the usual collar incision, he ligates the superior and inferior thyroid arteries of one side. He then dissects off the anterior wall of the capsule by blunt dissection and removes it. The gland is then enucleated in the ordinary way, and the remains of the posterior portion of the capsule plicated by interrupted silk sutures. A drainage tube is left in for 24 hours. The skin wound is closed with fine interrupted silk sutures. He is a painstaking, conscientious operator and a very neat dissector. I also watched his first assistant (Prof. Machol) do another goître operation in the same way.

The second morning I watched a very interesting operation. A young girl of 18, who had been operated on elsewhere four months previously for acute appendicular abscess, came to the clinic with a fæcal fistula. The appendix had not been discovered at the first operation. Under ether-drop narcosis (administered by a lady assistant), Garré dissected out the fistula right up to the cæcum. It was not continuous with the lumen of the appendix, which was obliterated at its origin from the cæcum. He closed up the sinus and removed the appendix. In doing this latter, he did not invaginate the stump as we do, but simply cut it off almost flush with the cæcum, and put in a double row of interrupted silk Lembert sutures. The closing of the abdominal wound was left to an assistant, which method, I think, is a mistake, in these cases at least.

The orthopædic and surgical polyclinic in this clinic was the last word in efficiency.

A very interesting feature of the Bonn University clinic was the private department attached for patients who did not desire to go into the public wards, and yet who were not in a position to pay the big fees demanded at the private institutions in the town. The ordinary German ward patient is paid for by his Krankenkasse, or sickness insurance society. In Bonn the fee is two marks per diem. In Berlin it is 4½ marks per diem. At the Garré clinic a number of well-appointed bedrooms are set aside for private patients of inadequate means. These are divided into two classes: the first class pay ten marks, the second pay six marks per week. No fee is accepted for the operation. We inspected some of these rooms, and I have seen worse rooms at home at 30s. and 40s. per week. Prof. Garré also has a large private hospital—the Johannis Hospital, in the vicinity of the University Klinik.

Garré is of a very quiet personality, broad-minded and well acquainted with English and American surgical literature. He lectures in a quiet, conversational voice, and is not nearly so dogmatic as less well informed men whom I have met, both at home and abroad. He was exceedingly courteous, and put every opportunity in my way of seeing all I could in a short space of time.

FRANKFURT.

The surgical clinic at Frankfurt-am-Main is in charge of Prof. Rehn, who is best known, perhaps, for his adventurous researches in cardiac surgery. In 1892 Rehn was the first surgeon successfully to suture a bad stab-wound in the heart. Since then he has done many cases. What his pioneer efforts have led to may be shown by the fact that up to two years ago there were 127 successful cases recorded in Germany alone.

In none of the many German clinics that I have visited have I ever been so struck with the spirit of geniality and "bonhomie" as in Rehn's clinic. One feels oneself indeed in a "Heilanstalt" in the truest sense of the word.

Rehn possesses 240 surgical beds in his hospital, and we saw some highly interesting work. The first morning we were present we watched him carry out Förster's operation—section of the posterior nerve roots for gastric crisis in tabes. His *technique* is very good; he works fast and is ably assisted. In fact, watching him that morning, the truth of Moynihan's adage was well brought home to me: "Modern surgery is the work of a team, and not of one man." I have seldom seen such perfect accord between an operator and his assistants during an operation.

The preparations for the operation were very interesting. The operators stood before big nickel bowls, into each of which a sister poured about half a pint of liquid soap; warm water was then run in from a tap, and a really prodigious lather ensued. The hands are well washed in this for eight minutes with a nailbrush, then rinsed in sterilised water. Next, the hands and arms are scrubbed in absolute alcohol with soft pads of lint for five minutes. As the quantity of alcohol used daily is very large, Rehn has an ingenious device by which, after every washing, the used alcohol is carried off and redistilled for the next morning's use. In this way a great economy is effected. The actual amount used daily is measured by a controller on the main tap. The hands and arms are then dried, and dry thin rubber gloves are put on with the usual cap and mask. Iodine is used on the skin, except in laparotomies; in these cases Rehn is of opinion that iodine leads to post-operative peritoneal adhesions, and the abdomen is well scrubbed with large balls of lint soaked in equal parts of turpentine and benzene. Silk is used throughout; catgut only very rarely, as at Bonn, for muscle suturing.

I attended the operating theatre on two successive mornings. On each Prof. Rehn himself performed the first operation, leaving the subsequent simpler ones to his assistants. The first morning, he carried out a section of the 7th, 8th, and 9th dorsal nerve-roots for very severe tabetic gastric crises in a man of 54 years. The entire operation took 41 minutes. Rehn is different from other Continental operators whom I have seen, in that he always sutures his skin-wounds himself, and does not leave this portion of the operation to an assistant. He stitches rapidly and with his left hand. The patient lay full on his face. The anæsthetic was administered admirably, considering the difficult position, through a Roth-Dräger apparatus by his military assistant, Stabsarzt Dr. Bettke. Narcosis was induced with chloroform, and continued with ether. Considering the amount of divided tissues, there was surprisingly little hæmorrhage. The dura was closed with fine silk, muscles sewn together with iodised catgut, and skin sutured with very fine interrupted sutures.

The following morning I again watched him perform a thymectomy on a child nine months old. A three-inch incision was made upwards and outwards from the left sterno-clavicular articulation, the capsule of the gland opened, and the gland gently extracted. There was some slight difficulty at the last moment owing to strong adhesions between gland, capsule and pericardium. The entire operation took 17 minutes. The anæsthetic was pure ether, again with the Roth-Dräger apparatus. During both these operations a special nurse was told off to observe the pulse continuously, and warn the operator of any serious fall or rise.

More interesting, however, than the actual cases operated upon, were several special cases that Prof. Rehn himself showed us in his wards. Two were pericardiotomies for gross suppurative exudations into the pericardial sac. Rehn is of opinion that most cases of serous pericardial effusion go down from severe pressure on the heart. He is fortified in this opinion by the fact that during a recent six weeks' absence four patients died without operation in the medical clinic, who would otherwise have been operated upon and probably saved. The two patients I saw were young male subjects, one 12 years and the other 18. Both had suffered from severe streptococcal pericarditis: the older subject had been found, stabbed, in a wood outside the town; both pericardium and lungs had been pierced, but the heart had escaped. A very severe pyopneumo-thorax had ensued. Both patients, when I saw them, looked on the road to recovery. The younger had been operated upon two days before my visit, the stab-wound case two months before.

Another highly interesting case that was shown us was that of a little girl, aged 14. Two years ago Rehn had operated upon her for ectopia vesicæ in the following manner: The ileum had been divided across and the proximal end anastomosed (end to side) with the transverse colon. The cæcal portion had been closed. The ascending colon had likewise been cut across and each end closed. Thus the cæcum, part of the ileum, and part of the ascending colon now formed a fully closed sac. At the same sitting an appendicostomy was performed, and a permanent catheter left in its lumen. This artificial bladder was now washed out several times daily for three weeks with saline and hydrogen-peroxide solutions. At the end of three weeks the trigone of the bladder, with ureters attached, was implanted into the cæcum. Uninterrupted recovery ensued, proper retention of urine, and no kidney infection. The child had now come back to the clinic complaining of pains in the new bladder region. On X-ray examination, seven urinary calculi were discovered. Unhappily we could not wait to see this highly interesting case operated upon.

Attached to the surgical clinic is the well-known Institut für Experimentelle Chirurgie, under the charge of one of Prof. Rehn's assistants, Dr. Klose, who has published some highly interesting original work on the surgical aspects of Basedow's disease, and of thymus affections in both children and adults.

Heidelberg.

At Heidelberg we visited the clinic of Prof. Wilms, who is best known to us, perhaps, by his work on the cæcum mobile. We saw him perform several very interesting operations. The first was on an old man of 67, who was suspected to be suffering from gastric cancer, supervening on a chronic ulcer. The anæsthetic was ether, administered through the ever-present Roth-Dräger apparatus, by a young girl, recently qualified and serving as a Voluntär-Assistintin. Wilms decided not to do a gastrectomy, on account of the age and feeble frame of the patient, but did a posterior gastro-enterostomy instead, using a rather long loop. He stitched with a triple line of interrupted silk sutures, which were tied at an unusually rapid rate by his first assistant. The whole operation took 19 minutes.

The second case was a very interesting one. A boy, aged 11 years, was suffering from bilateral dislocation and fixation of the hip-joints, due to a severe suppurative arthritis two years before. On this case Wilms carried out a very ingenious operation of his own device. Using the usual Lagenbeck incision, he completely loosened and separated all the adhesions between the femur and ilium. The head of the femur had been completely absorbed, and the acetabulum was so shallow that a proper *restitutio ad integrum* was out of the question. He thereupon loosened a layer of periosteum and bone, as a kind of overhanging shelf, from the dorsum ilii just above the acetabulum, and let it hang directly over the remains of the head of the femur. Between these two structures he transplanted a large, square piece of fat taken from the gluteal region. The skin-wound was then sutured without drainage, and the leg put up in plaster of Paris in the extended, abducted and everted position. After the operation he showed us X-ray pictures of two other similar cases on which he had carried out an identical procedure some years before, and in which a pseudarthrosis had formed, with excellent functional result. In the present case, he purposed operating on the other hip at an interval of two to six months hence. The operation was carried out rapidly and decisively, with no hesitation, and was highly ingenious.

We watched him do yet a third case—a prostatectomy, under local anæsthesia. The anæsthesia was faultless, and the patient an old man of over 70. Wilms follows neither the Freyer nor the Young method, but has devised a rapid and very effective perineal enucleation of his own. The patient being placed in the lithotomy position, a cut is made radially from the anus to the left ischial tuberosity. With his gloved finger as guide, he plunges a knife into the under part of the prostatic capsule, and rapidly enucleates the gland, which is held steady by means of a Young's retractor, passed per urethram, and held by an assistant. On account of its hardness, he sent the gland to be examined for possible carcinoma. There was practically no hæmorrhage. A large drainage tube was inserted, which was to be left in till the sixth day. The whole operation took only three and a half minutes, and appealed to us very much for its simplicity, rapidity and excellent drainage. He told us he had done over 150 of these cases by this method, and found it, in his hands, superior to the methods of Young and Freyer, both of which he had tried. He had no recurrence, and as he always operated under local anæsthesia, had no unpleasant post-operative lung complications. Sepsis rarely caused him any trouble, as the drainage was excellent. He further stated that William Mayo, who had visited the clinic two years before, had adopted this method, and had since written to him to express his complete satisfaction with the results he had obtained.

With this account I close. I saw many other operations and operators, but have chosen what appeared the most interesting points in a highly interesting tour, and have set them forth, somewhat untidily and unconnectedly perhaps, in the hope that it may prompt some of our fellow Irish surgeons, and particularly the younger ones, to spend even as profitable and as pleasant a visit with our German colleagues.

OPERATING THEATRES.

MIDDLESEX HOSPITAL.

Intestinal Obstruction from Ileal Kink Due to Adhesions.—Mr. Sampson Handley operated on a married woman, æt. 28, who had been admitted in the evening with pain over the abdomen, especially over the lower part, and sickness since the morning. Temperature was 98.6° and pulse 116. She gave a history of salpingo-oöphoritis two years ago, and was operated on by another surgeon, when both the ovaries, tubes and the uterus were removed. She was much better after the operation, but since last six months she complained of getting large in the abdomen. Examination showed the abdomen to be very tender, distended and slightly rigid. She was operated on the same night. The abdomen was opened under open ether anæsthesia by a median subumbilical incision through the old scar. Several adhesions to the pelvis were found. The appendix was adherent, and there was a distinct ileal kink present near the cæcum. The fibrous bands were divided, appendix removed, normal saline put in the abdomen, and the wound closed by figure-of-eight and through-and-through sutures. Patient passed a fair night after the operation, but there was hardly any result with the rectal tube and a good deal of distension was present. One-fiftieth grain of eserin salicyl was given subcutaneously. There was a fair result with the rectal tube the next morning, and moreover the patient passed flatus naturally. The pain disappeared altogether on the third day. Temperature went up slightly after the operation, but came down to normal on the third day and kept such during the whole convalescence. Since then the patient made an uneventful recovery, and was discharged quite well.

Intestinal Obstruction and Paresis of Part of Small Intestine.—The same surgeon operated on a married woman, æt. 53, who had been admitted in the morning with all the symptoms of acute intestinal obstruction. The patient gave a history of a former operation in 1908 by another surgeon, who did a subtotal hysterectomy for fibroid and rigid salpingo-oöphorectomy. She felt quite well after the operation till last few months, when she had been getting colicky pain off and on, which used to pass off shortly. She was getting constipated gradually. For the last three weeks before she came in there had been no proper opening of the bowel, and she was getting definitely larger in the abdomen. There was not much pain and very little sickness. She very rarely passed flatus these days. But since three days the abdomen had become more distended and the pain increased. She had been vomiting greenish fluid with an offensive odour. Temperature was subnormal and pulse 124.

Examination showed the abdomen enormously distended, very rigid and tender; there was visible peristalsis present in the upper part. She vomited twice in that day. A stomach tube was passed, and a fair amount of the liquid stuff was brought out. The same evening she was operated on under general (open) ether anæsthesia. The abdomen was opened in the middle line by an incision about 5½ inches in length. There were great fibrous adhesions between the coils of intestines, the omentum and the peritoneum. These were thoroughly freed. The intestines were brought out, and it was found that the whole of the small intestine was enormously distended. There was partial paralysis of the lower part of the jejunum, but definite peristalsis was felt in the upper part. No definite constriction in the intestinal wall was found. With two punctures, one on the right and the other on the left, a large amount of green, liquid, fæcal matter was let out, and the openings were closed by purse-string sutures. Then a lateral anastomosis was made between the ileum and the cæcum. All this time the intestines were kept moist with warm saline. Then normal saline was poured into the abdominal cavity, which was then closed by figure-of-eight and through-and-though sutures. Patient's condition was very bad at the end of the operation, and she was ordered to have pituitary extract and eserin subcutaneously and high rectal tube for saline. Her condition still got worse and the pulse was very feeble. Three pints of normal saline were given intravenously, the legs were bandaged, the foot of the bed raised, and she had also subcutaneous saline under both breasts. By these means the patient got over the shock, though she passed a most anxious night. The next morning the patient looked much better. Bowels opened twice, and the same sort of green stuff came out. There was good result with the rectal tube—especially after eserin. The temperature was 96.9° and pulse 112. Bowels have been kept open regularly ever since, and there were healthy formed stools since the third day. Temperature went up to 100° and the pulse came down to 98 on the third day. The patient improved and felt better every day ever since. Stitches were taken out on the tenth day. The temperature and pulse were nearly normal. She has been improving steadily ever since without any interruption, but for a mammary abscess due to the infection of the saline with B. coli. She is getting up now and is probably going out within a couple of days.

TRANSACTIONS OF SOCIETIES.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

The thirty-second annual session of this society was opened at the West London Hospital on Friday last, October 3rd, when

Dr. F. S. Palmer was inducted as the new President.

The first duty he had the pleasure of performing was the presentation of the Keetley Memorial Medal to his predecessor in office, and a very hearty vote of thanks was accorded to Dr. G. P. Shuter, the retiring President, for the time and trouble he had devoted to the interests of the Society, and for the able way in which he had acted as its chairman. It was hoped this replica of the original medal inscribed with Dr. Shuter's name and year of office would be a pleasant memento to him, while it served to perpetuate the memory of the late Mr. C. R. B. Keetley, founder of the Society.

Dr. F. S. Palmer then delivered his presidential address, entitled

A GENERAL VIEW OF MALINGERING,

which will be found in another column under the heading "Original Papers," page 393.

Prior to the formal business of the evening cases were shown by Mr. N. Bishop Harman, and the meeting closed with a vote of thanks to Dr. F. S. Palmer for his interesting and opportune address.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Oct. 4th, 1913.

FURUNCULOSIS.

The treatment of boils and furunculosis is well known at present through the researches of Prof. Mauté, who developed his method in the *Journal des Praticiens.*

Taking at first the negative side of the question, M. Mauté eliminates from the treatment all that was hitherto regarded as classical. He is entirely opposed, for instance, to the application of tincture of iodine, or to a solution of iodine and acetone; these applications have no effect on the progress of the infection. Surgical treatment is also useless; opening the tumour and removing its contents is absurd, the incision of the boil is painful and leaves an ugly cicatrix behind. The knife should be reserved for anthrax. Baths, however antiseptic, should not be prescribed before the second week after the eruption has disappeared.

M. Mauté's method of treatment is as follows:—Apply to each boil a small piece of compressed cotton-wool (*cataplasme*) the exact size of the tumour and maintain in position by narrow strips of adhesive oxide of zinc plaster. The part should not be enveloped in layers of cotton wool, as in the case of ordinary wounds. As soon as suppuration is ended all dressing is removed If the boil remains hard and inflamed, a little collargol ointment may be applied—

Collargol, 1 dr.
Vaseline, 1 oz.

Where a group of boils exist, each one should be treated separately; no large occlusive dressings should be applied To disinfect the surrounding skin and thus avoid re-inoculation, lotions of spirit of camphor may be used, after which the region is powdered with

Talc powder, 4 oz.
Peroxide of zinc, 1 oz.

The general treatment consists in inoculations of antistaphylococcic vaccine. The vaccine employed by M. Mauté is prepared with the microbe of the patient (auto-vaccine). Each cubic centimetre contains 1,000 millions of microbes. Where the furunculosis is in the acute stage, an injection of a quarter of a c.c. (250 millions) is made every four days; after the fourth injection the dose is increased to half c.c. (500 millions), given once a week, or seven or eight injections in all.

In 80 per cent. of the cases the boils will not return after the first four injections; in 15 per cent. it may be necessary to prolong the injections; in the remaining 5 per cent. the treatment fails, but these cases are generally due to diabetic intoxication. Laxatives are useful throughout the treatment:—

Sulphate of soda,
Rochelle salt,
Bicarbonate of soda, aa 1 oz.

Two teaspoonfuls each morning in a glass of hot water.

Fissure of the Anus.

This painful affection is rapidly cured by the application of a three per cent. solution of blue of methylene after washing the parts with oxygen water. The same treatment is efficacious in sore nipples and pruritus of the vulva.

GERMANY.

Berlin, Oct. 4th, 1913.

At the Wissenschaftlicher Verein, Stettin, Hr. Haeckel demonstrated a

Series of Cases of Calculus.

The first was that of a calculus of unusual size removed from the ureter of a woman, æt. 30. The pelvis of the kidney was first reached through an oblique incision in the loins; it was then opened, but nothing but fine concretions and fat were found. The ureter was then opened by an incision along the upper surface. The calculus was situated under the linea innominata, and it struck the operator as curious that there was no dilatation of the ureter above the obstruction. At first the intention was to push up the stone so that it could be removed through the opening thus made, but this mode of procedure had to be given up, as the blood vessels supplying the parts would have suffered from the manipulations. An incision had then to be made above the stone, and through this it was removed. Suture of the ureter and of the wound, except for two drains. Uninterrupted recovery. It was absolutely necessary to preserve the pelvis of the kidney, as Röntgen examination of the other kidney showed a large calculus there which would have to be removed on a later occasion. The calculus was 3.5 c.m. in length and 1.2 in diameter.

The second case was one of vesical calculus, in which the incrustations had formed round a centre of paraffin. The patient had suffered a great deal from cystitis. There was great difficulty in getting the calculus into view, as the body was so easily moved through the fluid contents of the bladder. Sectio alta was performed and recovery was uninterrupted. The calculus, the dimensions of which were 2.4, 1.7, 1.2 c.m., was translucent; it had a thin coating of lime, and consisted of a pencil of paraffin doubled up. The patient, who was a sailor, admitted, after some persuasion, that a pencil of paraffin, the thickness of a lead pencil, had been passed into his urethra in a brothel, that the pencil had broken off, leaving a part in the bladder. The paraffin appeared to have very quickly set up a good deal of pain in the bladder. The speaker thought it possible that more of the cases of urostealith met with might be set up in the same way.

The third case was one of urethral calculus occurring in an unmarried woman, æt. 21. She had sought medical advice on account of great pain and inconence of urine. A little more than a c.m. from the orifice of the urethra a stone was encountered; it could also be plainly felt from the vagina. It was easily removed through an incision in the anterior vaginal wall. Continence returned after removal of the calculus. The speaker pointed out the great rarity of urethral calculi in women. According to the last edition of Veit's handbook, only ten cases of the kind has been recorded. The stone did not lie in a diverticulum, but in the mid-passage of the urethra.

Hr. Kalb showed two patients for whom foreign bodies had been removed from the gastro-intestinal canal. The first case was that of a psychopath who had had laparotomy performed three times on account of spoon-handles that he had swallowed, and which had stuck at the pylorus. The other patient was a child who had swallowed a pin, which had pinned the jejuno-duodenal flexure. The parts were separated and the pin removed.

At the Unteressässischer Aerztverein, Hr. Weill showed a case of

Pulsating Exophthalmos.

The case was that of a youth, æt. 17, who two months before had had a fall from a bicycle, which resulted in unconsciousness and vomiting. Consciousness returned in 48 hours. The eyelids were swollen, and he remarked a disagreeable rushing noise in the left side of the head. There were now exophthalmos, dilatation of the veins, which were felt to pulsate synchronously with the radial pulse. Vision was good. Accommodation paralysed. In the fundus oculi there was enormous fulness of the veins, nothing abnormal in the papilla. When the left carotid was compressed the pulsation ceased, and the patient felt relieved. The explanation of the condition was believed to be fracture of the base of the skull with rupture of the internal carotid artery with communication with the sinus cavernosus. The pulse wave was communicated to the whole eye through the superior ophthalmic vein. Treatment consisted in ligature of the carotid, which, however, was not free from danger, and, moreover, it did not always lead to the desired result. The speaker had had an apparatus constructed that set up in a simple manner slight compression of the cervical part of the carotid.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

EDINBURGH.

Edinburgh Post-graduate Courses.

The post-graduate courses of 1913, which have just ended, have been more successful in point of the numbers attending them than in any previous year. They were participated in by 111 graduates, as compared with 99 in 1912. Half of the entrants, it is said, came from within our own shores and half from the Colonies and the United States. Concomitantly with the rising number of students, the number of teachers and the number of classes have also increased. This year no less than 79 teachers gave instruction. Of late years the post-graduate courses have developed along a line somewhat different from that intended by the originators seven or eight years ago. In the first instance, the views of men who wished merely to spend a part of their holiday in getting a general brush-up all round were especially kept in view, but experience shows that this class tends to diminish in favour of men who come desirous of devoting several weeks of hard work at some special subject. At first these were catered for in August in a special course in medicine, and in September in a special course in surgery, reserving the bulk of the September course for general subjects. Gradually, however, the general course is being, as it were, encroached on by specially arranged courses. Thus, for the past two years a special course on diseases of children has been arranged in July, in which not only the medical and surgical aspects of pædiatrics are considered, but eye diseases, mental defects, otology, fevers and skin diseases, as they occur in childhood, are dealt with by specialists. Again, courses on laryngology and the allied subjects, a course on genito-urinary surgery, and courses on operative surgery have been organised; and it is hoped that courses on gynæcology may be arranged for, while probably some of the special branches of internal medicine will come in for more notice. It is really a matter for congratulation that the Edinburgh post-graduate courses show so much vitality, and those who taught in them this year are more than ever pleased and surprised at the hard and strenuous work done by the graduates.

On September 1st the Executive Committee gave a reception in the University Union to the graduates attending the course, in order that they might have an opportunity of becoming acquainted with the teachers. The guests were received by Prof. Harvey Littlejohn, Dr. J. W. Ballantyne, and Dr. J. D. Comrie. A feature of the September course was the series of special afternoon lectures, among the lecturers being Dr. Byrom Bramwell, Prof. Littlejohn, Sir Halliday Croom, Mr. Stiles, Dr. Allan Jamieson, Dr. Berry Hart, Dr. Woods Hutchinson, and others.

GLASGOW.

Wassermann Test in Relation to Public Health.

The Glasgow Corporation resolved some months ago to place the Wassermann reaction on the same footing as the test for typhoid fever, tuberculosis, and diphtheria, and to offer facilities to practitioners for having the test done by the health authorities. Provision has now been made in the Public Health laboratory for carrying out the test. The name of the patient is not asked, but particulars as to age, sex, occupation, leading symptom, and the ward of the city in which the patient lives are required. It is not intended that the reaction should be done in obvious cases of syphilis, but only in obscure cases. A fee of 2s. 6d. is paid for every sample of blood sent in for examination, and the requisite apparatus for collecting blood is supplied gratis. Unless we are mistaken, Glasgow is one of the first municipalities to afford such facilities, and in view of the fact that a definite crusade against syphilis cannot be much longer postponed, her action deserves all praise, and ought to be imitated elsewhere.

Clinical Research Laboratory at Glasgow Victoria Infirmary.

A new clinical research laboratory, the gift of Mr. William Robertson, was formally opened on October 2nd by Lord Rowallan, Chairman of Directors. Dr. Mackintosh, Superintendent of the Glasgow Western Infirmary, in describing the buildings, said they were second to none in the United Kingdom. The laboratory is a two-storey building, and on the first floor are rooms for preparing culture media, and a lecture room. Above, there is a large clinical laboratory, with chemical laboratory adjoining. There are also on this floor special weighing rooms, vaccine rooms, incubator rooms, and sterilising rooms.

Munificent Bequest to Glasgow University.

The late Dr. Tennent made a will about two months before his death by which he has bequeathed £25,000 to the governing body of Glasgow University, to be applied for such object or objects in connection with the Faculty of Medicine as his trustees may determine, and the remainder of his estate to the Western Infirmary, the Royal Infirmary, the Victoria Infirmary, and the Royal Hospital for Sick Children, Glasgow.

The Chadwick Trust Lectures.

The first lectures in Scotland under the provisions of the late Sir Edwin Chadwick's trust for diffusing knowledge on the subject of the health of nations were delivered in Glasgow last week. At the opening lecture, on October 1st, Principal Sir Donald Macalister presided. The lecturer was Mr. W. E. Riley, superintending architect to the London County Council. The Chairman referred to Chadwick as having been a demonstrator as well as an advocate of great measures of social improvement. The lecturer, in the course of his lecture, which was on London housing schemes, traced the causes of overbuilding, and described some of the extensive operations which the London County Council had carried out. In concluding, he discussed the largest clearance ever embarked on under the Public Health Act of 1890. This was the scheme dealing with Tabard Street and Grotto Place, Bermondsey and Southwark. The area had a total extent of 17 acres, the number of persons of the working class affected being 4,552. It had been decided that the central portion of the area, or about 5 acres, should be laid out as a public open space, and that the requisite rehousing accommodation should be provided in five-storey, balcony, block dwellings, overlooking the open space, with as many cottages as could conveniently be erected. The total net cost of the scheme was estimated at £389,000.

The Workmen's Compensation Act and Uncertified Deaths.

A case of uncertified death at Linlithgow, which occurred about two months ago, has led to some rather unusual proceedings, illustrating the working of the Workmen's Compensation Act. A vanman and salesman sustained injuries, it was alleged, through falling or being thrown from his van or lorry, and, he having died, his widow claimed compensation under the Act from his employers, on the ground that the accident arose out of and in the course of his employment. The employers, upon this, presented a petition to the sheriff for warrant to disinter the body, stating that the cause of the man's death was unknown, and could not be certified without a *post-mortem* examination. A medical man who saw the deceased shortly before his death and remained with him until he died, was, it was stated, unable to certify, and declined to certify the cause of death. The Sheriff, after hearing parties' solicitors, granted the order craved for the exhumation of the body.

Presentation to Professor Monro.

Professor T. K. Monro, who was till recently Professor of Medicine in St. Mungo's College, and who has been appointed to succeed the late Professor Samson Gemmell in the chair of that subject at the University, received on the 25th ult. a presentation from a number of his former staff at the Royal Infirmary. Dr. H. H. Borland presided, and the presentation was made by Dr. Campbell Marshall. As Professor of Medicine in the University, Dr. Monro will now teach clinically in the Western Infirmary.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE TEACHING OF SCIENCE.

To the Editor of The Medical Press and Circular.

Sir,—Many of us are taking interest in the teaching of science in our schools. Our old ideas have changed, and we don't feel so sure that classics and mathematics are all that we want our boys taught till they leave school and start on the life they are going to follow. We used to think it best to put off science teaching for those who were going into the medical profession till they began their hospital life, and that they were better prepared for this, mentally and physically, by what was taught them at school, and by the exclusion from their studies of those subjects to which they would have to give thought and time when they started for medicine.

It is quite clear to us now that science and a knowledge of modern languages are necessary for those who are going to follow the practice of medicine, and that the boys who have some knowledge of this kind have a great advantage over those whose school teaching has been limited to classics and mathematics. Science may be of little practical use to those who are going into the Church or the Law, but now a knowledge of science, generally and specially, is of such great importance in many occupations which provide those that follow them with the means to live well and independently, that our schools are obliged to distinguish clearly between what they call the classical and the modern sides. At our chief universities the greatest changes have taken place, and the science schools have grown up in a remarkable manner.

Now, if we were asked to state clearly and simply what science we should like our boys taught at school, when the medical profession is what we have settled for them, we should not find it easy to draw up a system of study which could be carried out in our great public schools.

In the teaching of science we have to follow such a different plan from that which is best for mathematics and classics. It is not from books alone that science is to be learnt, if it is to be turned to practical use in professional life. Very little encouragement has been given at most of our schools to the teaching of science, and the classical side has assumed a superiority over it, and has treated it with a kind of contempt that has led those who would be most capable as teachers to hold back from and avoid it. There is another very important point which has to be considered, and that is the proper provision in schools of the rather expensive apparatus that the teacher must have if he is to teach well, and which he certainly cannot be expected to provide at his own expense. To lecture well on such subjects as heat, light or electricity requires apparatus, and when we consider what a wide subject chemistry is, we must allow that it is difficult to decide how it can be taught at schools. Probably the best answer we must make to the question how we would like our boys taught would be that we should leave this in the hands of those who we are sure are capable as teachers and are provided fully with what they require in their lecture rooms and laboratories, and that there should be no mean payment allowed for the work they are carrying on. There is not the least doubt but that in this country teachers are not paid properly and that a very different view is taken in Germany, France and our Colonies of what is the great value of such work. It would be well if more attention were given by the medical profession to the teaching of science, and that it should not be left to those who have no practical knowledge of the practical purposes to which science teaching can be turned in professional life.

I am, Sir, yours truly,
L.

ON THE ACCURACY OF THE "MEDICAL REGISTER," WITH A NOTE ON MEDICAL CERTIFICATES.

To the Editor of The Medical Press and Circular.

Sir,—May I once more ask you for your valuable assistance in reminding members of the profession that, unless their names appear in the *Medical Register*, they are not "legally qualified medical practitioners" (Medical Act, 1858, Section 34), and that the duty of notifying changes of address rests with them.

No person can "hold any appointment as a physician, surgeon, or other medical officer either in the military or naval service or in emigrant or other vessels, or in any hospital, infirmary, dispensary, or lying-in hospital, not supported wholly by voluntary contributions, or in any lunatic asylum, gaol, penitentiary, house of correction, house of industry, parochial or union workhouse or poorhouse, parish union, or other public establishment, body or institution, or to any friendly or other society for affording mutual relief in sickness, infirmity, or old age, or as a medical officer of health, unless he be registered" (Section 36); and "no certificate required by any Act now in force, or that may hereafter be passed, from any physician, surgeon, licentiate in medicine and surgery, or other medical practitioner, shall be valid unless the person signing the same be registered" (Section 37).

The *Medical Register* is the only official publication, and it should not be confused with any of the various directories which issue circulars annually.

No one who is not familiar with the work of this office would believe the amount of trouble which is taken to keep in touch with practitioners, and to find them when touch has been lost, but, unless we are assisted by members of the profession themselves, our efforts are often fruitless.

In consequence of cases which have recently occurred it becomes increasingly important every year that the Registrar should carry out the duty laid upon him under Section 14 of removing from the *Register* the names of practitioners with whom he cannot communicate. It is done with reluctance, but only by this means can the public and the profession be protected against inpostors. No doubt cases of hardship do sometimes arise in consequence of this removal of names, but every possible source of information is made use of to save practitioners from the results of their own forgetfulness, and if they are inconvenienced by finding that their names are off the *Register*, the blame does not rest with this office. The duty of notifying changes of address rests with practitioners; the Registrar is obliged to send communications to registered addresses only, but the practice is to make use of every available source of information.

I therefore hope that all practitioners who have any doubt as to the accuracy of their addresses in the *Register* will communicate with this office without delay, and, if they will give their full names and qualifications in legible writing, it will be of great assistance to us. All communications will be duly acknowledged.

Perhaps I may add that, by a recent regulation, practitioners possessing medical and dental qualifications, if already on the *Medical Register*, may register in the *Dentists' Register*, or vice versa, for a reduced fee of £2 1s., instead of £5 1s.

I should like to take the opportunity of drawing attention to the following resolution adopted by the Council on November 30th, 1911; it cannot be urged too strongly upon practitioners that, in giving certificates, they are recognised by law as members of a trusted profession, and that it behoves them to exercise the greatest possible care in the matter:

> Whereas registered medical practitioners are in certain cases bound by law to give, or may be from time to time called upon or requested to give, certificates signed by them in their professional capacity, for subsequent use either in courts of justice or for administrative purposes: And whereas such certificates include, *amongst others*:
>
> (*a*) Under any statute relating to births, deaths, or disposal of the dead;
>
> (*b*) Under the Lunacy Acts;
>
> (*c*) Under the Vaccination Acts;
>
> (*d*) Under the Factory Acts;
>
> (*e*) In relation to children, or to excusing school attendance;
>
> (*f*) In connection with sick benefit, insurance, and friendly societies;
>
> (*g*) In connection with workmen's compensation;
>
> (*h*) In connection with naval or merchant shipping;
>
> (*i*) For procuring the issue of Foreign Office passports;
>
> (*j*) For excusing attendance in courts of justice, in the public services, in public offices, or at ordinary employments;
>
> And whereas it has been made to appear to the General Council from time to time that some registered medical practitioners have given and signed untrue, misleading, or improper certificates of the above specified or other descriptions.
>
> Now, therefore, the General Medical Council hereby give notice that any registered medical practitioner who shall be shown to have given any untrue, misleading or improper certificate, whether relating to the several matters above specified or otherwise, is liable to be adjudged by them to be guilty of "infamous conduct in a professional respect," and have his name erased from the *Medical Register* under Section 29 of the Medical Act, 1858.

I am, Sir, yours truly,
Norman C. King,
Registrar.

299, Oxford Street, London, W.,
September 26th.

NEWSPAPERS AND QUACKERY.

To the Editor of The Medical Press and Circular.

Sir,—In a letter in your paper of this week one of your correspondents writes: "The trade in nostrums engages a vast amount of capital; it suborns great numbers of newspapers," etc., etc. An illustration of this fact has been since afforded in many leading papers, London and provincial. Having observed it in one, I have sought it in more, and I enclose specimens. These papers, as you will see, all publish more or less lengthy reports of a speech of Dr. Robert Simpson, of Plymouth, on the subject of medicated wines at a recent meeting of the Temperance League. He pointed out that during recent years a new factor had arisen in the temperance problem which threatened to become a very serious obstacle in the way of reform unless it was recognised and steps taken to combat its evil effects. He referred to the introduction in a most attractive form of so-called medicated wines. Dr. Simpson showed how the insidious danger of these products was increased many fold before the public, chiefly because of their food values, or the tonic or medicinal values which they were supposed to possess. Dr. Simpson urged that the public lost sight of the fact that in order to obtain a very small quantity of nutriment they had to swallow a considerable amount of alcoholic stimulant. It was a not uncommon thing to find persons who were total abstainers taking these preparations in utter oblivion of the fact that they were practically drinking ordinary wine. Numbers of cases of inebriety, he added, owed their origin to indulgence in some form or other of medicated or tonic wines.

These utterances of Dr. Simpson's, wise and admirably adapted as they are to his audience, are, of course, mere commonplaces to the medical profession, and especially to those who, like myself, devote much attention to the "temperance" question. What I want to call the attention of my medical brethren to is the fact which the enclosed cuttings will show—viz., that leading newspapers, whilst printing Dr. Simpson's speech, publish in other pages, or even in adjacent columns, huge illustrated advertisements of the compounds he denounces. Can the astute managers and owners of these papers be ignorant of the evils he exposes; and how do they reconcile their conduct in the field of money-making with the lofty morality preached in the editorial columns? Ingenuous readers, seeing Dr. Simpson's speech in one page and the advertisement of a wonderful cure-all in another, would need nothing more to lead them to swallow the poisonous baits; they must believe that any advertisement in such a high-toned paper would be above suspicion.

I am Sir, yours truly,
MEDICAL TEMPERANCE REFORMER.

October 2nd, 1913.

RACIAL PREJUDICE IN MEDICAL PRACTICE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In giving your advice that Indian doctors in England should go and practise in their own country, are you not pandering to the prejudice of the few and unwittingly doing an injustice to a great number of His Majesty's subjects? The Indians might retaliate and say that because some of their countrymen are prejudiced against the English, therefore the English doctors in India should leave the country and come home and practise here. In the palmy days of Rome, when a man became a Roman citizen he had perfect freedom to serve in any part of her dominions. Unless the idea of British Empire is a farce and a sham, Indians (who come from the same Aryan stock as the English) should have as much liberty to practise where they like as the English or any other of His Majesty's subjects.

I am, Sir, yours truly,
D. J. A. C. MUTHU, M.D.

Wells, Somerset.
October 4th, 1903.

[There is no getting over the fact that anyone who attempts to practise medicine as a foreigner with a colour distinction, be it a negro in England or an Englishman in China, must be prepared to put up with a good deal of racial prejudice. Our comments were based on an entirely sympathetic attitude, and it was pointed out that in spite of such opposition it was possible to attain considerable and sometimes even brilliant success in the United Kingdom. There is, of course, no legal impediment in the way of such a settlement.—ED. M.P. and C.]

THE OATMEAL INSTINCT IN HYPOTHYROIDISM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Recent experiments of the American Board of Health have shown that mice fed on oatmeal can take with impunity a dose of prussic acid forty times as great as that which would prove fatal to the ordinarily fed animal. It is further found that the effect of the oatmeal is not only a chemical reaction, but an increase in the activity of the thyroid gland.

I have under my care a patient suffering from hypothyroidism, and she evinces an extraordinary craving for oatmeal. This has often been noticed in anæmic and chlorotic conditions, and must be, I think, a physiological instinct for food substances which activate the thyroid gland, of which the secretion is usually subnormal in these cases.

I am, Sir, yours truly,
J. C. MCWALTER, M.D.

Dublin.
September 28th, 1913.

REVIEWS OF BOOKS.

MEDICO-LEGAL BOOKS.

Sir John Collie's book on *Medico-Legal Examinations and the Workmen's Compensation Act* (*a*) will be found of much help to all medical men who are concerned with the examination of claimants under the Act. Probably no medical man in the Kingdom has a larger experience of this kind of work than Sir John Collie, and while he has full sympathy with the workman injured in the course of his employment, no one is more clever or resourceful in detecting fictitious or imaginary claims. From the storehouse of his experience he brings forth many histories which are typical of the various improper claims that are put forward, often, it is to be feared, with the connivance of members of the medical profession. Sir John gives a brief but clear and helpful summary of the provisions of the Act. In another chapter he enumerates some of the more peculiar decisions which have been given by the courts, and we must agree with him that there is some excuse for those who think that the intentions of the framers of the Act have been largely extended in favour of the workman by the recorded decisions. Indeed, no matter how flagrant may be the breach of discipline which causes an accident, the employer seems to be responsible. Sir John Collie closes with reasonable suggestions for the amendment of the Act. He presses strongly—and here again we agree with him—for a much wider employment of medical referees, and for giving them extended powers.

The Trial of William Palmer (*b*).

has more matter of interest to medical readers than some other volumes of the "Notable Trials Series." Palmer was himself a medical man, a fact which had a considerable bearing on the history of the crime. The number of medical witnesses examined was enormous—no less than thirty-two out of a total of sixty witnesses. It can hardly be claimed, moreover, that out of so great a multitude any great certitude emerged. The case to this day presents difficulties. That Palmer murdered his friend Cook is fairly certain, and there is good reason to believe that several other persons, including his illegitimate child, his mother-in-law, his wife, and his brother, were also his victims. The circumstances of the death of Cook, however, for whose murder Palmer was hanged, are still far from clear. The week prior to his death, while in company with Palmer, Cook suffered from vomiting and diarrhœa, a circumstance on which the Crown relied as evidence of attempted poisoning by tartar emetic. From this sickness he recovered, but he died a few days later with undoubted symptoms of poisoning by strychnine. The *post mortem* analysis by Taylor failed to discover strychnine in the body, but established the presence of antimony. For Taylor's failure to find strychnine, of poisoning by which he maintained that Cook died, he was unable to offer a satisfactory explanation. For the defence much medical evidence was led to suggest that the symptoms on which the Crown relied as evidence of strychnine poisoning might be

---

(*a*) "Medico-Legal Examinations and the Workmen's Compensation Act, 1906." By Sir John Collie, M.D., J.P. Demy 8vo, pp. 128. London: Bailliere, Tindall and Cox. 1912. Price 5s. net.

(*b*) "The Trial of William Palmer." Edited by George H. Knott Barrister-at-Law. (Notable English Trials.) Edinburgh: Williams, Hodge and Co., 1912. Pp. xii. and 320. Price 5s. net.

due to other causes, such as epilepsy, syphilis, and idiopathic tetanus, but it failed to convince the judge or jury. Some interesting ethical points arose in the history of the case. The leading medical witness for the prosecution, Dr. Taylor, was so foolish as to discuss the case in a letter to the *Lancet* prior to the hearing. On the other hand, the leading counsel for the defence, Mr. Sergeant Shee, committed an equally grave breach of etiquette. In his address to the jury he laid stress on his personal conviction of the innocence of the prisoner. Mr. George H. Knott, who edits the volume, has performed his duties carefully and judiciously.

Drs. Robertson and Mc Kendrick's epitome of *Public Health Law* (*a*) is a wonderfully concise and comprehensive volume. In the space of four hundred pages the authors give the essence of the various public health laws in force in Scotland, in England and Wales, and in the United Kingdom. Various references to laws applicable only to London or to Ireland are given in their proper places. The index might have been a little fuller with advantage, but there is, as a matter of fact, little trouble experienced in finding the desired references. The volume will be invaluable as a handy guide to all concerned with public health administration in Great Britain.

Dr. F. J. Smith's *Law for Medical Men* (*b*) is a book of quite different scope. It is not specially concerned with public health law, though that subject is by no means ignored. It is not, on the other hand, a text-book of forensic medicine. It may, however, be regarded as the necessary supplement to such a text-book, in that it furnishes the legal documentation which cannot conveniently be given in the ordinary text-book. Dr. Smith's position as one of the leading medical jurists in England is a guarantee of the soundness of his work. He opens with a valuable chapter on the Acts of Parliament relating to the several licensing bodies of the Kingdom, and quotes the disciplinary powers possessed by each body. Speaking generally, these powers are most precise and most extensive in the case of the younger corporations. We miss any reference to the powers of the Royal College of Physicians of London with regard to the control of medical practice in London. There is an excellent chapter on the functions and powers of the General Medical Council. Contrary to general opinion, it appears that there is a legal definition of "infamous conduct in a professional respect." This was given by the Court of Appeal in 1892—"if it is shown that a medical man, in the pursuit of his profession, has done something with regard to which it would be reasonably regarded as disgraceful or dishonourable by his professional brethren of good repute and competency, then it is open to the Council to say that he has been guilty of infamous conduct in a professional sense." The application of this principle to concrete cases will, of course, present many difficulties, and the judgment of the Council will alter with the development of the sense of the profession as to what is honourable and proper conduct. We have not space to follow Dr. Smith through his summary of the various laws of importance to medical practitioners. The value of the summary is greatly enhanced by the author's judicious discussions on the various points. He expresses himself with force and decision, and we gratefully add, with humour.

Malingering, (*c*) by Sir John Collie deals with the same question, but covers a much wider field. It is curious that so little has been systematically written on the subject of malingering, and the appearance of a work dealing therewith is peculiarly appropriate at the present time. The responsibilities cast on medical men under the National Insurance Act increase greatly the importance to the profession of a knowledge of malingering. It is true that in regard to this Act the medical man is in a better position to detect malingering than is the medical examiner in a case of claim for compensation, since, under the Insurance Act, it is, at any rate in the first instance, the patient's own medical attendant who has to come to an effective decision. Any medical man who has to examine patients who may be suspected of malingering will learn much from Sir John Collie. He is an old hand, and is apparently up to all the tricks. It is true that the incautious reader may be so carried away by Sir John's shrewdness as to be anxious to detect fraud where there is none, though we do not think that this is the author's own attitude. He appears to us scrupulously fair, even if very searching. The medical examiner's object should be the discovery of truth, and not the pecuniary benefit of either the claimant or the person on whom the claim is made. After a few introductory chapters, Sir John Collie deals systematically with the examination of the various organs of the body. He then discusses points which may give rise to special difficulty, such as the relations to malingering of hernia, epilepsy, and insanity. He gives useful advice as to the conduct of a medical witness in court, and as to the drawing up of medical reports for perusal by laymen. Not the least helpful part of the book is the introduction of reports of illustrative cases. Sir John Collie is very severe—sometimes unduly so, though there is much excuse for warm feeling and straight speech—in his criticism of other medical men who may have differed with him at one time or other. We do not know what he would say if he heard one of his *confrères* suggesting, as he does (page 235), that "a temperature" is a sign of fatty degeneration of the heart. It is probably only looseness of expression which permits him to speak (page 119) of sound "reaching the brain through the bones of the skull." We commend Sir John Collie's book as an able and helpful expression of personal views and unique knowledge on a subject of much importance.

OUR OUTSIDES. (*a*)

The talented author of this extremely interesting book is far too modest in his prefatory remarks concerning its aims and objects. After such rich mental fare as "Herbal Simples" and "Precious Stones," we expected something good from between its enticing brown covers, and we have not been disappointed. The ability to read character from facial or cranial conformation is one possessed by only a chosen few, but medical men have abundant opportunities for exercising the art of character-telling. Every part of the visible person is dealt with systematically in this volume, and yet there is remarkably little of the text-book about it. Rather is it a rich collection of observations respecting the features, temperament, gait, hand-shaking, stature, the hands, the feet, the finger-nails, mannerisms, &c.; in short, nothing about the human personality that indicates in any manner character or disposition appears to be omitted. The antiquarian and collector of epigrams, and all lovers of literature will simply revel in this anthology of folk-lore and philosophy regarding our externals. The author is right when he speaks of "nursing morose discontent until the feeling becomes a morbid chronic ailment." So do a man's habitual thoughts impress themselves indelibly upon his countenance. The ladies will be comforted by the reflection that "facial wrinkles appear sooner in a man than in a woman; and they are deeper in nervous men, whose faces are very mobile." The more advanced section of woman-

(*b*) "Law for Medical Men: A Book for Practitioners, Containing Extracts from Acts of Parliament Interesting to Medical Men." By Fred. J. Smith, M.D., F.R.C.P. Pp. xii. and 402. London: J. and A. Churchill, 1913. Price 10s. 6d. net.

(c) "Malingering and Feigned Sickness." By Sir John Collie, M.D. J.P., Assisted by Arthur H. Spicer, M.B., B.S., D.P.H. Illustrated Pp. xii. and 340. London: Edward Arnold. 1913. Price 10s. 6d. net.

(*a*) "Our Outsides: and what they Betoken." A Summary, by W. T. Fernie, M.D., Author of "Herbal Simples," &c. Pp. xv., 413. Bristol: John Wright and Sons, Ltd. 1913. Price 4s. 6d.

kind will not be pleased with the remarks on page 363 as to the true functions of the gentler sex. Such minutiæ as the manner of wearing the hat (which, by the way, is always *Hat*!), or of blowing the nose (also *Nose*), the varying tones of the voice, the colour of the hair and eyes, and the attitude adopted when at rest, are all significant of mental traits, and as such may be regarded by the would-be physiognomist. These features cannot be hidden, but are open to the inspection of him who has eyes to see. As a charming companion for leisure moments we can cordially recommend Dr. Fernie's book to our readers, for it will assuredly have a very wide circulation indeed.

THE DISEASES OF CHILDREN. (*a*)

The fifth volume of "The Diseases of Children" is entirely devoted to the surgical aspect of this subject. This it treats from a general practitioner's point of view. Its aim is more to present a concise survey of those conditions in which surgical and orthopædic interference may become necessary, and the various procedures that may be employed in dealing with them than to give a detailed account of pathology and surgery for the specialist.

The writer, Dr. Hans Spitzy, who is responsible for nearly the whole of this part of the work, discusses most fully the methods he employs at the K.K. Kinderklinik at Gratz (Austria). Professor Fritz Lange, of Munich, contributes the articles on Deformities of the Vertebral Column and Thorax. The American translators have added a few comments.

The work is conveniently arranged for reference, and is divided into the following sections:—I., Congenital Diseases; II., Disturbances in Post-Fœtal Development; III., Surgical Infectious Diseases; IV., Injuries; V., Affections of Neurogenic Origin; VI., Tumours.

Section I., which would more appropriately come under the heading "Congenital Deformities," systematically discusses the abnormalities of each part of the body. Here, as throughout the work, in order to ensure correct diagnosis, there is a good deal of descriptive text. Pathology and treatment receive their share of attention. For instance, under hernia, Kocher's and Bassini's *technique* for its radical cure is fully described. Spitzy, in eleven hundred cases, had only four deaths; two from epidemics, one from pneumonia, and one from status thymicus. In nurslings he uses no anæsthesia, to avoid risk. His simplified operation on infants takes from four to eight minutes.

Section II. discusses principally scoliosis, flat-foot, and deformities due to rickets. Tuberculous diseases of bones and joints are fully considered in Section III. The writer does not believe in the routine removal of tuberculous glands, but prefers Bier's treatment, and the aspiration of pus as it occurs. He says (p. 211), "Up to 1904, 100 out of a total 500 operations annually in the author's service were for the removal and scraping out of glands. In the last four years, out of a total of 3,000 operations not more than three were for the removal of glands."

Section IV. contains some useful information on the treatment of fractures. The writer describes his results from neuroplasty, arthrodesis, etc., in Section V. The last section, on tumours, completes the work.

The fifth volume of "The Diseases of Children" contains 199 illustrations, most of which are good, and suitably depict the conditions referred to in the text. The reproduction of some of the skiagrams is poor. On the whole, this volume carries out its purpose well, and gives a good general review of Continental methods in sufficient detail to be instructive as well as interesting. The translators, Drs. Shaw, Manning, and Leo Wolf, have done their part to make the work a success.

SURGERY. (*a*)

The concluding volume of "Keen's Surgery" is written with the object of bringing the previous five volumes up to date, as it was found that although the last of them was published as recently as 1909, the progress of surgery has been so rapid as to call for the revision of much of the earlier matter. A few new chapters have been added to provide for the discussion of such subjects as recent apparatus for operating on the thorax, Moltzer and Auer's method of anæsthesia, the surgery of the hypophysis, the use of salvarsan, the intra-venous injection of ether as an anæsthetic, etc. This volume also contains a general index of all six volumes.

The present method of bringing out an additional volume, when revision is required within a short time, is an eminently practical and sound plan, and one which, if adopted widely in works of large size, will mean a considerable saving of expense to medical readers.

SURGERY OF THE LUNGS. (*b*)

Nothing could exceed the interest and completeness with which the subject of lung surgery is treated by Professors Garrè and Quincke in the second edition of their book. We have never read a book which dealt more satisfactorily with each question of difficulty and with so many in a short volume. It indeed brings home to us how much behind Continental surgery our British conservatism has left us. Of particular value are the chapters on thoracic anatomy and the methods of producing differential pressure in thoracic surgery, while in Chapter V. pros and cons of treatment in injury to the lung are brilliantly argued. Unfortunately, the faulty punctuation makes the translation hard to follow, and occasionally the English itself is obscure. For instance, on page 110 is the following:—"So that within an extensive zone of suppuration, softening inflammation often only isolated spots develop gangrene, or . . . ." The above is inexcusable, yet a study of the excellent teaching in the volume will, we hope, stimulate our surgeons to lay less timid hands on that sanctuary of disease—the thorax.

LAWS OF SEXUAL PHILOSOPHY. (*c*)

The object of this book is to bring to the student of gynæcology and obstetrics a psychological sketch of the history of the sexual life of the human race, and an exposition of Eastern and Western sexual science, from the medical, moral and social point of view. The author, Dr. Chundra, of Calcutta University, has a reputation as an authority on historical unexplained aphorisms connected with Hindu sexual science, and this book bears many marks concerning an exceedingly important but difficult subject, and which are treated in a tactful and plain manner.

In the first chapter, the laws of menstruation are dealt with, considering its definition, history, the superstitions connected with it, whether it be a physiological or pathological process, the purpose of menstruation, and the management of menstruation, with its anomalies, derangements, and the menopause. In the second chapter are given the laws of the reproductive organs, followed by laws concerned with sterility, sexual life, instinct and intercourse, sexual inversion and perversion, and marriage are discussed with valuable historical notes.

The ignorance concerning sexual matters which exists amongst girls and young women is incredible and is most probably the basis of many of our social ills, and anyone honestly endeavouring to solve the difficult problem of sexual matters will find a great help in making themselves acquainted with the contents of this small manual.

(*a*) "The Diseases of Children." A work for the Practising physician. Edited by Dr. M. Pfaundler and Dr. A. Schlossmann. English Translation edited by Henry L. K. Shaw, M.D., and Linnæus La Fétra, M.D. In five volumes. Illustrated by 90 full-page plates in colours and 773 text cuts, of which 72 are in colour. Vol. V. Pp. iv. and 364. Philadelphia and London: J. B. Lippincott Company. 1912. Price 21s. 2d. net.

(*a*) "Surgery: Its Principles and Practice." By Various Authors. Edited by William Williams Keen, M.D., LL.D. Vol. VI. "The New Surgery," with general index to Vols. I. to VI. Illustrated. Pp. 1,177, with index. Philadelphia: W. B. Saunders Company. 1913. Price 34s.

(*b*) "Surgery of the Lung." By C. Garré and H. Quincke. Translated from the German by David M. Barcroft, M.D., 2nd edition. Pp. 258. London: John Bale, Sons and Danielsson.

(*c*) "Laws of Sexual Philosophy." By J. L. Chundra, of Calcutta. 1913.

It may interest our readers to know that a little book by Dr. E. G. Younger, "Insanity in Everyday Practice," now in its second edition, has been translated into the Chinese language under the auspices of the China Medical Missionary Association, and is published in Shanghai. Dr. Cousland, one of the translators, says in his preface: "It should enable the Chinese practitioner to diagnose cases of insanity and make the best arrangements possible for their treatment, the latter by no means an easy matter in the almost total absence of asylums. Also it should enable him to recognise the beginnings of mental disorders when there is yet time for preventive treatment."

* * *

Volume I. of the *Dublin University Calendar* for 1913-14 has just been issued. In addition to regulations concerning the various University courses, and other information necessary to the student, this part of the Calendar contains the ordinary examination papers set in the academic year 1912-13. These papers do not appear to be arranged in any regular order, and are printed without an index.

MEDICAL NEWS IN BRIEF.

The Royal Society of Medicine—Section of Odontology.

The following regulations have been issued respecting grants in aid of scientific research:—

1. That the grants exist for the furtherance of scientific research in connection with dentistry.

2. That all grants shall expire on May 1st next following the date in which they are made, when a statement of expenditure shall be forwarded to the Hon. Secretary, 1 Wimpole Street, W.

3. That no part of any grant shall be applied in payment of personal expenses in connection with the research for which the grant has been made, unless a resolution to that effect has been duly passed by the Committee. Every recipient of a grant shall be deemed to have notice of these rules.

4. That when the whole of the expense of the enquiry has been provided by the Committee the result of the investigation shall be the property of the Section of Odontology of the Royal Society of Medicine.

In any case in which the author desires to publish a report of work done under a grant from the Committee, elsewhere than in the Transactions of the Society, it shall be a condition of the grant that the permission of the Committee be first obtained, and the following note be affixed to the published report:—"Towards the expenses of this reseach a grant was made by the Section of Odontology of the Royal Society of Medicine."

5. That apparatus purchased with the grant shall be the property of the Royal Society of Medicine, and be returned at the expiration of the grant, unless the Committee shall otherwise determine.

6. That a report shall be furnished to the Committee by the recipient of the grant (or an interim report if the object of the grant be not then attained) on April 20th, following the allotment, containing:—

(*a*) A brief statement of the report of the Scientific Grants Committee, showing the results arrived at or the stage which the enquiry has reached.

(*b*) A general statement of the expenditure incurred, accompanied, so far as possible, by vouchers.

(*c*) A list of the instruments, specimens, etc., purchased or obtained out of the grant or supplied by the Committee, which are still in the possession of the recipient.

(*d*) Reference to any Transactions, Journals, or other publications in which the results of the Research have been printed.

(*e*) If a renewal be desired an application should be sent at the same time.

New Laboratory for Glasgow.

Lord Rowallan, Chairman of the Governors, presided last week at the opening of a clinical research laboratory, given to the Victoria Infirmary, Glasgow, by Mr. William Robertson, shipowner. The laboratory is a two-storey building The first floor is described as the workshop, and will be used by the attendant for preparing the various media. In this portion of the building there is also a lecture-room. The flat above will be utilised for the laboratory proper. Here there is a large clinical laboratory, and adjoining it is a chemical laboratory, where tests and chemical examinations can be made. A special room has been fitted up for weighing in a fine balance. There is also a vaccine room, while other departments include a sterilising room and an incubator room. The laboratory has been built and equipped under the guidance of a committee, consisting of Dr. Donald Mackintosh, Superintendent of the Western Infirmary, Glasgow; Dr. Ebenezer Duncan and Dr. Grant Andrew.

A Florence Nightingale Memorial.

A memorial to Miss Florence Nightingale was unveiled the other day at Liverpool outside the Central Home of the Liverpool Queen Victoria District Nursing Association. Out of the funds collected four Florence Nightingale nurses have been endowed. The memorial, the erection of which was defrayed by the balance of the funds, takes the form of a panel representing Florence Nightingale carrying out the mission of her life to sick and suffering humanity.

Scarlet Fever in Birmingham.

A severe epidemic of scarlet fever is reported from Birmingham, 900 cases being under treatment in the isolation hospital. During the past week 223 fresh cases were notified to the authorities, and 232 in the previous week, which is the highest number since the extension of the city boundaries. Only seven deaths have been reported during the fortnight. A number of patients are treated in their homes, and it is estimated that there are at least 1,100 cases in the city.

London School of Tropical Medicine.

The winter session opened last week, sixty students having entered their names. The additional laboratories, rendered possible by the fund raised by Mr. Austen Chamberlain, are being occupied for the first time. The new course in Tropical Sanitation and Hygiene, open to students who have already attended the ordinary course, will be inaugurated this session, the first lectures being held about the 20th inst. The increased accommodation for resident students has also been made available, and all the rooms have already been let. The annual dinner will be held at Prince's Restaurant, Piccadilly, W., on Friday, October 24th, under the presidency of Dr. F. M. Sandwith.

Large Bequest to Glasgow University.

The trust settlement of Dr. Gavin Paterson Tennent, of Bath Street, Glasgow, dated July 3rd, 1913, has been lodged in the Register House, Edinburgh. He bequeaths £25.000 to the governing body of the University of Glasgow, to be applied for such objects or object in connection with the faculty of medicine as the trustees may determine. He also bequeaths the residue of his estate to the Western Infirmary, the Royal Infirmary, the Victoria Infirmary, and the Royal Hospital for Sick Children, Glasgow.

A Medical Man's Fatal Fall.

Last week, at the Marylebone Coroner's Court, Mr. C. Luxmore Drew held an inquest on the body of Henry George Walker, aged 70, a doctor of medicine, lately residing at Marloes Road, Kensington, who died from injuries received by falling down the well of a lift at a nursing home in Henrietta Street, Cavendish Square.

Dr. Arthur W. Read, of Southwell Gardens, said he went with Dr. Walker, who was a very delicate man, on Saturday to the nursing home to see a patient; while they were waiting for the lift Dr. Walker stepped backwards and fell down the well into the basement, a distance of about 15 feet. He did not know who had opened the gate of the lift, but it was opened, and he thought Dr. Walker might have done it.

A servant at the home stated that she pressed the button to bring the lift down from the floor above. The gate of the lift was open a few inches as the lock was not working, and she thought Dr. Walker must have opened it still further when he fell.

Dr. Edward Corner, of Harley Street, said that Dr. Walker suffered from heart disease, and death took place on Tuesday from syncope consequent upon the shock of the accident.

A verdict of accidental death was returned.

Treatment of Tuberculosis in Birmingham.

A report on the administration of sanatorium benefit in Birmingham during the year ended July 14th states that an agreement has now been entered into with the Birmingham Corporation for a period of 30 years under which the Corporation will provide the whole of the institutional treatment of insured persons suffering from tuberculosis and recommended by the Insurance Committee within the limits of accommodation and facilities provided by the Corporation's scheme for insured and non-insured persons. This scheme when in full operation will provide 409 beds at four sanatoria. The Broad Street Tuberculosis Dispensary will be able to deal with 2,000 patients a week. The treatment provided in the Corporation sanatoria has been widely appreciated, though 58 patients neglected or declined to take advantage of sanatorium treatment and 31 refused the dispensary treatment recommended.

A table giving the occupational incidence of pulmonary tuberculosis shows that engineers sent the greatest number for treatment—namely, 130 males and 18 females. The brass trade sent 120 males and 22 females. General labourers numbered 104. Domestic servants (103), pressworkers (66), warehouse workers (43), and clerks (36) are the heaviest totals on the female side. The average for the whole city is 1.9 per 1,000. The income for the year was £12,697, and the expenditure £11,849.

Damages for Neglect to attend a Panel Patient.

The question of the responsibility for the non-attendance of a panel doctor upon an insured patient was last week argued in a case which came before Judge Thomas at Liverpool County Court. George Titherington, a clerk, who is a minor, sued through his father to recover £2 6s. damages from Dr. John Dunlop, of Anfield, for failure or refusal to attend him after accepting him as a panel patient. Plaintiff, his counsel said, caught a chill after playing football, and next morning began to spit blood. His parents sent for Dr. Dunlop, on whose panel plaintiff was. The doctor was out, but a message was left that the case was urgent. As the doctor had not called three hours later, counsel went on, two of plaintiff's sisters went to his house at 6.30. They saw the doctor, and asked if he intended to come or not, to which the doctor replied, "I can't go now; I wan't recreation just as much as anyone else does; I will come as soon as it suits me." Counsel added that if the Court accepted the evidence of the plaintiff, this was clearly a case where the doctor ought to be compelled to pay the fees which the plaintiff's father had been obliged to pay because the defendant would not attend a patient whom he had accepted. Dr. Dunlop never attended the plaintiff at all, for about eight o'clock the boy's condition became such that Dr. Nixon was sent for and at once took up the case, which proved to be one of pneumonia.

Evidence having been given, counsel for defendant submitted that it was the Insurance Committee's obligation to provide people with medical treatment. The Insurance Committee made arrangements with the doctors, and it was with the Insurance Committee alone that the plaintiff could deal. If there was any failure on the part of the defendant, it was the Committee's default, and the plaintiff must call the Committee to answer for it.

His Honour found against the defendant on the legal points, and upon the facts expressed the opinion that the defendant had been actuated by temper at what he considered the ill-behaviour of the girls. He gave judgment for the plaintiff for the amount claimed, with costs, and allowed an appeal.

King's College Hospital.

The annual dinner of past and present students of King's College Hospital took place last week at the Waldorf Hotel under the presidency of Viscount Hambledon, Chairman of the Hospital and of the Medical School. During the afternoon many past students visited the new King's College Hospital at Denmark Hill, and were conducted over the building by the Dean and other members of the staff, being afterwards entertained at tea. It was stated that the opening of the hospital for out-patients would take place about the middle of October. Among those present at the dinner were Dr. Arthur William May (Director-General of the Medical Department of the Navy), Sir C. P. Lukis (Dirctor-General of the Indian Medical Service), Mr. A. Boyce Barrow (Consulting Surgeon to the Hospital), Professor Nestor Tirard (Senior Physician of the Hospital), Professor Sir Watson Cheyne (Senior Surgeon), Sir Ronald Ross, Sir St. Clair Thomson, Professor W. R. Smith, Professor Ernest White, and Dr. G. E. Shuttleworth.

Royal Naval Medical Service.

At the examination for appointments as Acting Surgeons, Naval Medical Service, held on September 29th and October 1st and 2nd, 13 candidates were successful and obtained the following marks:—J. S. Elliott, M.B., 1,703; A. J. Tonkinson, M.B., 1,68 A. R. Sharrod, M.B., 1,643; G. J. Kilbride, M.B., 1,578; A. E. Panter, B.A., 1,515; G. S. Harvey, M.B., 1,483; J. P. Blockley, M.B., 1,470; W. H. Murray, M.B., 1,455; J. R. Haldane, M.B., 1,455; G. H. Hayes, M.B., 1,435; W. S. Birch, 1,418; H. C. A. T. Cannon, 1,380; H. J. Hopps, M.B., 1,338. The maximum number of marks obtainable is 2,400.

Middlesex Hospital Medical School.

The following scholarships, medals, prizes and certificates were awarded at the opening of the winter session last week for the session 1912-1913:—

Broderip Scholarship, A. O. Gray first, C. E. Thornton second; Lyell Medal and Scholarship, A. O. Gray; Freeman Scholarship, C. E. Thornton; John Murray Medal and Scholarship, F. W. Browne; Hetley Clinical Prize, T. B. Paul; Leopold Hudson Prize, H. A. Lucas; New Zealand Scholarship, T. Julian; Second Year's Exhibition, D. W. J. Andrews.

Prizes were awarded to the following:—In Medicine, F. E. Feilden; Surgery, F. E. Feilden; Practical Medicine, F. E. Feilden; Practical Surgery, C. P. Sells; Midwifery, O. C. Link; Practical Midwifery, O. C. Link; Pathology, T. C. Kidner; Psychiatry, H. C. Samuel; Forensic Medicine and Public Health, T. C. Kidner; Pharmacology, E. H. Lake; Anatomy, D. W. J. Andrews; Physiology, D. W. J. Andrews; Practical Anatomy, D. C. Ogilvie; Histology, E. H. Lake; Embryology, W. T. Warwick; Practical Pharmacy, L. G. Lunnon; Biology, G. Howorth; Organic Chemistry, F. C. Mason; Inorganic Chemistry, M. B. Tench; Physics, A. I. Cox.

Special certificates were also awarded to a large number of students beyond the foregoing scholarship and prize lists.

Entrance Scholarships.—First Entrance Scholarship, S. C. Shaw; Second Entrance Scholarship, O. L. C. Sibley; Third Entrance Scholarship, G. F. W. Howorth; University Scholarship, J. J. O. Beven; Freer Lucas Scholarship, L. W. Hefferman.

Medical Scholarships.

The following awards of scholarships and exhibitions are announced:—

Guy's Hospital Medical and Dental Schools.—Senior Science Scholarships for University Students:—£50, Arthur Gerald East, St. John's College, Oxford; Junior Science Scholarships—£120, Eric Clark Hinde, Preliminary Science Class, Guy's Hospital; £60, Frederick Currer Hiller, St. Paul's School; Entrance Scholarship in Arts—£100, Eric Roland Webb, Dean Close School, Cheltenham; £50, Gordon Frank

Peters. Certificate:—Myles Wheeler-O'Brien, Oratory School, Edgbaston. Open Scholarship in Dental Mechanics:—£20, Hugh Muir Smith; Scholarship in Dental Mechanics for Pupils of Guy's Hospital—£20, George Dee.

London Hospital Medical College—(1) Price Scholarship in Science—£100, C. S. Cloake; (2) Price Scholarship in Anatomy and Physiology for students of the Universities of Oxford and Cambridge—£52 10s., L. G. Jacob, Christ's College, Cambridge; (3) Science Scholarship—£50, Mr. G. Adler.

University College Hospital Medical School.—Goldsmid Entrance Exhibitions—First, T. H. Somervell, Caius College, Cambridge; second, J. Vincent Bates, Pembroke College, Cambridge; proxime accessit, G. Y. Oliver, University of London, University College.

University College, London.—In the Faculty of Medical Sciences, the Bucknill Scholarship (135 guineas) and the 1st Medical Exhibition (55 guineas) has been divided equally between M. H. Oldershaw, Brighton Municipal Technical College and University College, and D. J. Thomas, St. David's College School, Lampeter, and University College of Wales, Aberystwith. W. Feldman, Central Foundation School and University College, is classed as 2nd Medical Exhibitioner (without emoluments). The Epsom Free Medical Scholarship is awarded to E. V. Correy. In the Faculty of Engineering, a Goldsmid Entrance Scholarship (£30 a year for three years) is awarded to H. P. Gardham, of Bancroft's School.

University of Glasgow.

The following candidates have passed the fourth (final) professional examination for the degrees of M.B. and Ch.B.:—

Douglas Kinchin Adams, M.A., B.Sc.; Nora Maud Aden Allan, Emile Agustine Cameron Beard, Simon Harry Bloom, William Adam Brechin, David Peebles Brown, Margaret Jarvey Brown, Benjamin Cohen, Wallace MacCallum Conley, M.A., Nathaniel Crichlow, Lawrence Crombie, Daniel Augustine Cush, Gabriel Daniel de Kock, Joseph Dunbar, William Campbell Fleishmann, William Forsyth, William Fotheringham, Ian Dingwall Grant, John Galloway Hendry, William John Henry, George Hislop, Mary Pringle Hislop, William Hornsby, Alexander Lindsay, Douglas M'Alpine, James Learmont M'Bean, John Aloysius M'Connochie, L.A.H.Dub.; James Walter M'Donald, John MacInnes, Annie Rankine M'Kail, Donald Mackinnon, James Robertson Cowper Mackintosh, Robert M'Lean, Andrew Paton Martin, Osborne Henry Mavor, Archibald Underwood Millar, M.A.; Michael Murphy, Archibald Naismith, Thomas Murray Newton, James Purdie, Angus M'Innes Ramsay, David Smith, William Robertson Snodgrass, M.A., B.Sc.; William Rowland Taylor, Carel Johannes van Lingen, Robert Bruce Wallace, Matthew White, M.A.

Royal College of Surgeons in Ireland.

The following is the list of awards gained in the examinations during the winter session 1912-13:—

Systematic Anatomy. First (£2) and medal, H. M. Alexander; second (£1) and certificate, K. Elmes.

Practical Anatomy.—First year: First (£2) and medal, H. Graham; second (£1) and certificate, H. M. Alexander. Second year: First (£2) and medal, J. A. M'Kinnon; second (£1) and certificate, D. J. Steele.

Practice of Medicine.—First (£2) and medal, Robert P. Weldon; second, no award.

Surgery.—First (£2) and medal, Trevor S. Smith; second (£1) and certificate, W. Lumley.

Midwifery.—First (£2) and medal, G. M. C. Powell; second, no award.

Pathology.—First (£2) and medal, D. V. O'Connor; second (£1) and certificate, J. O'Brien.

Physiology.—First (£2) and medal, H. M. Alexander; second (£1) and certificate, H. Graham.

Chemistry.—First (£2) and medal, James F. Seale; second, no award.

Physics.—First (£2) and medal, J. F. Seale; second (£1) and certificate, D. J. Steele.

Dental Anatomy.—First (£2) and medal, T. Edwards.

Summer Session, 1913.

Barker Anatomical Prize (£26 5s.), D. V. O'Connor.

Carmichael Scholarship (£15),, C. W. Robinson.

Mayne Scholarship (£8), G. E. Pepper.

Gold Medal in Operative Surgery, no award.

Silver medals in Operative Surgery, E. B. Palmer, and E. Connell (equal).

Stoney Memorial Gold Medal, J. A. Fretton.

Practical Histology.—First (£2) and medal, J. A. M'Kinnon; second (£1) and certificate, L. L. Glick.

Practical Chemistry.—First (£2) and medal, H. L. Mooney; second (£1) and certificate, W. E. Cook and J. G. Thornton (equal).

Public Health and Forensic Medicine.—First (£2) and medal, M. Moran; second (£1) and certificate, H. G. Villiers.

Materia Medica.—First (£2) and medal, C. W. Robinson; second (£1) and certificate, M. Moran.

Biology.—First (£2) and medal, M. Briscoe: second (£1) and certificate, G. Dunne and J. F. Seale (equal).

Surface and Topographical Anatomy.—First (£2) and medal, J. A. M'Kinnon; second (£1) and certificate, K. Elmes.

The Schools re-opened on October 1st. The above prizes will be distributed by the President, Mr. Richard Dancer Purefoy, on Wednesday, October 15th, at 1 p.m.

NOTICES TO CORRESPONDENTS, &c.

☛ Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

Subscriptions may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS

For One Insertion:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

Reprints.—Reprints of articles appearing in this Journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

Contributors are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 8, Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

Original Articles or Letters intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

L. S. A. (London, W.).—Hypophysis extract has proved very useful for labour pains. It is given by subcutaneous or intramuscular injection in doses of 0.5 to 1 c.c. once, or, if necessary, several times. It is said to be most effective in the first stage of labour in primiparæ, when the os is about four-fifths dilated, and in the second stage the employment of the drug may dispense with the use of forceps.

THE HISTORICAL MEDICAL MUSEUM.

In response to numerous requests, it has been decided to defer the closing of the Historical Medical Museum in Wigmore Street, London, W., until October 31st. During the month of October it will remain open from 10 a.m. to 6 p.m. daily, and from 10 a.m. to 1 p.m. on Saturdays. After this date it will be closed for a few months for re-arrangement as a permanent museum. It is proposed to re-open the museum in its permanent form in the spring of next year.

W. F. R. (Sussex).—According to Dr. L. Robsinson, the genio-glossus muscle has more to do with articulate speech than any other muscle of the tongue. In man the muscle is large, while it degenerates to a mere slit in the pig. It comes into action during every sound we utter, and in the case of a man speaking 150 words a minute its movements are from 400 to 500 per minute.

Dr. Marshall (Edinburgh).—Is thanked for his communication; the changes referred to have been noted for correction in a future issue.

Meetings of the Societies Lectures, &c.

Thursday, October 9th.

Royal Society of Medicine (Section of Obstetrics and Gynæcology) (1 Wimpole Street, W.).—8 p.m.: Opening remarks by the President, Dr. W. S. A. Griffith. Specimen: Dr. Macnaughton-Jones: Pyosalpinx of Accessory Tube. Short Communication: Dr. Macnaughton-Jones: Case of Complete Absence of the Internal Genitalia. Papers: Dr. Frances Ivens: Report of 26 cases of Adnexal Tuberculosis. Dr. Williamson and Dr. Mackenzie Wallis: The Serum Diagnosis of Pregnancy, with a Demonstration of Apparatus and Methods.

United Services Medical Society (Royal Army Medical College, Grosvenor Road, S.W.).—5 p.m.: Presidential Address by Col. A. B. Skinner, A.M.S.

Friday, October 10th.

Royal Society of Medicine (Section of the History of Medicine) (1 Wimpole Street, W.).—5 p.m.: Professor Morris Jastrow. All Members of the Profession, including Students, whether Fellows of the Society or not, are invited to attend this meeting.

Royal Society of Medicine (Clinical Section) (1 Wimpole Street).—8.30 p.m.: Dr. J. D. Rolleston.

Monday, October 13th.

Medical Society of London (11 Chandos Street, Cavendish Square, W.)—8 p.m.: General Meeting. 8.30 p.m.: Introductory Address by the President, Sir David Ferrier, F.R.S., M.D., to be followed by a paper on "Varieties of Facial Spasm and their Treatment," by Dr. Farquhar Buzzard.

Royal Society of Medicine.—5.30 p.m.: Demonstration by Dr. Hideyo Noguchi of pure cultures or spirochætes and of his recent researches upon the virus of rabies.

Appointments.

Bell, R. G., M.D.Glasg., F.R.C.S.Edin., Certifying Surgeon under the Factory and Workshop Acts for the Sunderland District of the county of Durham.

Coombe, T. S., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory and Workshop Acts for the Hoo District of the county of Kent.

Elliott, G. M., M.B., Ch.B.Edin., Resident Physician at the Edinburgh Royal Infirmary.

Fairweather, D. O., M.B., Ch.B.Edin., Surgeon to the Out-patient Department at the Edinburgh Royal Infirmary.

Gedge, A. S., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory and Workshop Acts for the Pewsey District of the county of Wilts.

Hartley, J. N. J., M.B., Ch.B.Edin., Resident Surgeon at the Edinburgh Royal Infirmary.

Laird, A., M.B., Ch.B.Edin., Surgeon to the Out-patient Department at the Edinburgh Royal Infirmary.

McKelvey, D., M.B., Ch.B.Edin., Resident Surgeon at the Edinburgh Royal Infirmary.

Owen, A. D., M.R.C.S., L.R.C.P.Lond., Medical Officer of Health to the Hampton-on-Thames Urban District Council.

Robertson, R. K., M.B., Ch.B.Edin., Resident Surgeon at the Edinburgh Royal Infirmary.

Shepherd, W. M., M.B., Ch.B.Edin., Resident Physician at the Edinburgh Royal Infirmary.

Von Ronn, H. A., M.B., Ch.B.Edin., Resident Surgeon at the Edinburgh Royal Infirmary.

Vacancies.

Argyle and Bute Asylum, Lochgilphead.—Assistant Medical Officer. Salary £175 per annum, with furnished apartments, board, and laundry. Applications to the Medical Superintendent.

James Murray's Royal Asylum for Lunatics, Perth.—Physician-Superintendent. Salary £700 per annum, with furnished house and emoluments. Applications to Condie, Mackenzie and Co., W.S., Perth.

Manchester School for Mothers.—Medical Officer. Salary £250 per annum. Applications to the Hon. Secretary, Medical Sub-committee, 339 Oxford Road, Manchester.

Northampton County Asylum, Berry Wood, Northampton.—Junior Assistant Medical Officer. Salary £200 per annum, with board, lodging, and washing. Applications to Medical Superintendent.

Leyton, Walthamstow, and Wanstead Children's and General Hospital.—Resident House Surgeon. Salary £100 per annum, with rooms, board, and washing. Applications to James Bird, Secretary, The Hospital, Orford Road, Walthamstow, N.E.

Park Hospital for Children, Hither Green, London, S.E.—Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing. Applications to the Clerk to the Metropolitan Asylums Board, Embankment, London, E.C.

Metropolitan Hospital, Kingsland Road, N.E.—Pathologist and Registrar. Salary £120 per annum. Applications to J. C. Buchanan, Secretary and House Governor.

The Hospital for Sick Children, Great Ormond Street, W.—Medical Registrar. Honorarium £200 per annum. (See advt.)

Certifying Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointments:—Bungay (Suffolk), Clacton-on-Sea (Essex), Gillingham (Dorsetshire), Shefford (Bedfordshire), Willenhall (Staffordshire).

Bethlem Hospital.—Resident House Physician for six months. Complete board and washing, and an honorarium at the rate of £25 per quarter. (See advt.)

Births.

Barris.—On September 28th, at 50 Welbeck Street, W., to Dr. and Mrs. John Barris—a daughter.

Boulton.—At Rockcliffe, Mussoorie, India, to Major Harold Boulton, I.M.S., and Mrs. Boulton (*née* Maud Mary Garton)—a daughter.

MacDonald.—On October 3rd, at 4 Buckingham Terrace, Glasgow, the wife of Dr. David MacDonald (*née* Olive P. Agar), of a son.

O'Grady.—On October 3rd, at 52 Lower Mount Street, Dublin, the wife of Major Standish O'Grady, R.A.M.C., of a daughter.

Ridout.—On September 30th, at St. Elmo, Clarendon Road, Southsea, Hants, the wife of C. A. Scott Ridout, M.S., F.R.C.S., of a son.

Wilson.—On September 22nd, at 108 Chevening Road, Brondesbury, N.W., the wife of Thomas Wilson, F.R.C.S., of a son.

Marriages.

Bennett—Taylor.—On October 3rd, at St. Clement's Church, Ste. Madelaine, Trinidad, Richard Charles Bennett, M.B., C.M., of Palm Grove, Princes Town, Trinidad, W.I., to Rose Florence, elder daughter of Mr. and Mrs. G. W. Taylor, "Cliftonville," The Polygon, Southampton.

Mole—Holmes.—On September 30th, at St. Gabriel's, Warwick Square, S.W., Harold F. Mole, F.R.C.S., of 19 Mortimer Road, Clifton, elder son of the late F. M. Mole, of Westfield Road, Edgbaston, to Harriet (Hetty), youngest daughter of the late Reuben Holmes, of Heanor, Derbyshire.

Deaths.

Brown.—On September 30th, at 77 Fitzjohn's Avenue, N.W., William Carnegie Brown, M.D., M.R.C.P., aged 54.

Fairbank.—On October 3rd, suddenly, at Felixstowe, Caversham, Oxon., Frederick Royston Fairbank, M.D., F.S.A., aged 72.

Last.—On October 2nd, at Bletsoe, Littlehampton, Grace Bevington, beloved wife of Cecil Edward Last, M.R.C.S., L.R.C.P.Lond., and daughter of the late John Stephen Jarvis and Mrs. Jarvis, of 75 Addison Road, W.

Norris.—On September 29th, at 15 City Walls, Chester, Deputy-Surgeon General Nathaniel Norris (retired list), in his 83rd year.

Thorp.—On October 3rd, at 39 Henley Road, Ipswich, from pneumonia, Henry John Thorp, M.D., aged 81.

Walker.—On September 30th, in a Nursing Home, as the result of an accident, Henry George Walker, M.D., of 5 Marloes Road, Kensington, W.

OPERATIONS—METROPOLITAN HOSPITALS.

WEDNESDAY.—St. Bartholomew's (1.30 p.m.), University College (2 p.m.), Royal Free (2 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. Thomas's (2 p.m.), London (2 p.m.), King's College (2 p.m.), St. George's (Ophthalmic, 1 p.m.), St. Mary's (2 p.m.), National Orthopædic (10 a.m.), St. Peter's (2 p.m.), Samaritan (9 30 a.m. and 2.30 p.m.), Gt Ormond Street, (9.30 a.m.), Gt. Northern Central (2.30 p.m.), Westminster (2 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), Cancer (2 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).

THURSDAY.—St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), University College (2 p.m.), Charing Cross (3 p.m.), St. George's (1 p.m.), London (2 p.m.), King's College (2 p.m.), Middlesex (1.30 p.m.), St. Mary's (2.30 p.m.), Soho Square (2 p.m.), North-West London (2 p.m.), Chelsea (2 p.m.), Great Northern Central (Gynæcological, 2.30 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), St. Mark's (2 p.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).

FRIDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), Guy's (1.30 p.m.), Middlesex (1.30 p.m.), Charing Cross (3 p.m.), St. George's (1 p.m.), King's College (2 p.m.), St. Mary's (2 p.m.), Ophthalmic (10 a.m.), Cancer (2 p.m.), Chelsea (2 p.m.), Great Northern Central (2.30 p.m.), West London (2.30 p.m.), London Throat (9.30 a.m.), Samaritan (9.30 a.m. and 2.30 p.m.), Throat, Golden Square (9.30 a.m.), City Orthopædic (2.30 p.m.), Soho Square (2 p.m.).

SATURDAY.—Royal Free (9 a.m.), London (2 p.m.), Middlesex (1.30 p.m.), St. Thomas's (2 p.m.), University College (9.15 a.m.), Charing Cross (2 p.m.), St George's (1 p.m.), St. Mary's (1 p.m.) Throat, Golden Square (9.30 a.m.), Guy's (1.30 p.m.).

MONDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), St. George's (2 p.m.), St. Mary's (2.35 p.m.), Middlesex (1.30 p.m.), Westminster (2 p.m.), Chelsea (2 p.m.) Samaritan (Gynæcological, by Physicians, 2 p.m.), Soho Square (2 p.m.), Royal Orthopædic (2 p.m.), City Orthopædic (4 p.m.), Great Northern Central (2.30 p.m.), West London (2.30 p.m.), London Throat (9.30 a.m.), Royal Free (2 p.m.), Guy's (1.30 p.m.).

TUESDAY.—London (2 p.m.), St. Bartholomew's (1.30 p.m.), St. Thomas's (3.30 p.m.), Guy's (1.30 p.m.), Middlesex (1.30 p.m.), Westminster (2 p.m.), West London (2.30 p.m.), University College (2 p.m.), St. George's (1 p.m.), St. Mary's (1 p.m.), St. Mark's (2.30 p.m.), Cancer (2 p.m.), Metropolitan (2.30 p.m.), London Throat (9.30 a.m.), Royal Ear (3 p.m.), Samaritan (9.30 a.m. and 2.30 p.m. Throat, Golden Square (93.0 a.m.), Soho Square (2 p.m.).

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVII. WEDNESDAY, OCTOBER 15, 1913. No. 16.

NOTES AND COMMENTS.

The Eternal Suffragette. SOME recent developments of the militant suffragette campaign deserve passing notice. Miss Lenton was last week committed for trial for maliciously setting fire to the tea pavilion at Kew Gardens in February last. The delay in the police court proceedings has been due to the state of her health. It may be remembered that she suffered from septic pneumonia as a result of forcible feeding. The first witness to tender evidence was a lady, one of the partners in the refreshment business carried on at the pavilion. The accused enquired of the witness, "Don't you think it would have been advisable to trade in your own name, that we might have known it was women's property?" The magistrate ruled that no answer was needed to so impertinent a question. It illustrates aptly the hopeless confusion of minds that have become criminal in their tendencies through sheer lack of intellectual training and of the restraining influence of a higher moral control. Well might the Mayor of Richmond say how deplorable it was to see a young woman (she is only 22 years of age) of great personal charms taking up a criminal movement and running the risk of committing suicide. Following the opinion expressed in these columns some time ago, he remarked that such conduct did not argue a rational state of mind.

The Hunger Strike. WHAT is to be done with these unhappy women who regard it as their duty to refuse food in prison? The intermittent imprisonment plan devised under what is known as the "Cat and Mouse Act," is far from satisfactory. Besides, why should its application be confined to suffragette offenders? A few days since the death was reported of a male prisoner, who had refused food. No attempt was made to feed him forcibly, so we gather, and he died of starvation. Why should he not have been released just as women are who refuse food? Clearly, our whole criminal system may be thwarted if the "hunger strike" becomes a common practice amongst criminals. There are rumours, however, that forcible feeding is to be resumed in the case of women offenders—just as it is carried out in the lunatic asylums. Why not? If society has to shut up individuals in gaols and madhouses, it must for the time being assume a certain responsible control over their welfare and see that they take their proper daily allowance of food, sleep and exercise. How can it stand by and permit prisoners to commit the further felony of *felo-de-se* without having something to say in the matter?

Militants and Medical Men. MILITANT suffragettes have turned their attention to members of the medical profession. At Holloway Gaol three of these misguided women waylaid the Deputy Governor and Medical Officer of the Prison, Dr. F. E. Forward. He explained to them that he was not responsible for the policy of forcible feeding. One of them, notwithstanding, assaulted him savagely with a sjambok, while the other two cut off his retreat. It is to be hoped that the perpetrators of this cowardly assault will be brought to justice. It seems that Sir Thomas Barlow incurred the anger of certain other ill-balanced viragos, who broke his windows in Wimpole Street. Several other houses were also singled out for attack, and the police in the Harley Street district have orders to keep a careful watch on suspected persons. If these foolish women deliberately take up arms against society, sooner or later their predatory warfare must end in melancholy disaster for each of them in detail and indefinite postponement of the female franchise. The patience of society has long been strained to breaking point. Social and political victories are no longer won by physical force. Women are inferior to men both in brains and in muscle, but less conspicuously so in the former. There could be no surer sign of degeneracy in womankind than the taking to fisticuffs.

A "Corner" in Radium. A RUMOUR is abroad to the effect that a company has been formed in London for the purpose of acquiring a radium monopoly. It is stated that negotiations are in progress between the Austrian Government and a British syndicate for the purchase by the latter of the Joachimsthal radium mine for £700,000, with the proviso that a specified percentage of the profits are to go to the Austrian Government. If the news be true, it affords an illustration of the greediness of capitalists who seek to pile up huge fortunes by "cornering" the necessities of life, such as flour, cotton, petroleum, and so on. Fortunately, so far as medical science is concerned, the value of radium has been grossly exaggerated. In spite of the vast sums of money that have been lavished upon its trial in the United Kingdom it is able so far to claim little therapeutical progress. Radium cures rodent ulcer, a fact that was early recognised: it relieves a few other conditions, but, generally speaking, it has proved a costly failure. So that even if the available supply of radium be kept in the hands of a few capitalists no great harm will have been done to suffering humanity. It may be, of course, that the future may bring its surprises with regard to the therapeutic virtues of radium, as it may with regard to many other agencies, whether presented by nature or begotten by the brain of man.

LEADING ARTICLES.

PARASYPHILIS.

IN recent years the interest of the medical profession in syphilis has been greatly stimulated by the many and startling discoveries that have re-written much of our knowledge of the subject. Of the various strongly marked characteristics of this disease not the least striking is that of latency, so that a man after apparent recovery may remain without symptoms for ten to twenty years or more, and then suffer from a tertiary attack in aggravated form. This potential latency, indeed, has long been the bugbear of the responsible medical man called upon to treat syphilis no less than the patient who seeks the service of his skilled directions. Gradually the term "parasyphilis" crept into medical practice. It was coined in order to denote in patients who had suffered from syphilis manifestations which could not be definitely termed syphilitic, but which occurred as a sort of syphilitic bye-product, which did not as a rule yield to antisyphilitic remedies; but which occurred with some amount of frequency in the shape of eruptions or "reminders," to use the apt phraseology of the late Sir Jonathan Hutchinson, or as definite nerve disorders, notably general paralysis of the insane and locomotor ataxy. The attitude of the medical profession during this period, in a word, was tentative and speculative, and it remained in that unsatisfactory condition until the introduction of the serum test of Wassermann revolutionised the diagnosis of syphilis. The blood of general paralytics and of tabetics was found to furnish evidence of syphilis in an overwhelming majority of cases. About the same time, or rather earlier, another epoch-making test was introduced, namely, the direct demonstration of the *Treponema pallidum* in the tissues of a patient. This latter test, however, was negative when applied to the parasyphilitics, including general paralytics and tabetics, as well as generally in tertiary lesions, where it was found rarely or not at all. Under these circumstances it was supposed that the deep cerebro-spinal syphilitic affections were in some way of toxic origin, or the results of processes started originally by the pathogenic organism or its products, while the specific spirillum had disappeared from the body. Some such view has been probably held by most medical men who have considered the subject of so-called parasyphilis within the last two or three years. Then came the announcement from America of an observation that has caused yet another quick change in our views. Professor Noguchi, director of the Rockefeller Institute, demonstrated the *Spirochæta pallida* in the brain of a tabetic. Coming from so distinguished a source, the fact has been accepted without question. Its consequences must be immediate and far-reaching. The illogical term parasyphilis, always a temporising confession of doubt and ignorance, will disappear from medical nomenclature. Henceforth a symptom or group of symptoms will be syphilitic or non-syphilitic; it will be no longer possible to relegate it to a no-man's region of parasyphilis. Then, again, it opens up a new hope for treatment of those terrible scourges of mankind, general paralysis and tabes, not to mention some forms of deafness and other syphilitic nerve troubles. If the cause of the progressive lesions be the *Spirochæta pallida* buried deeply in the nervous system, then it must be the task of the all-conquering scientist to find some way of bringing his germicide remedies to bear upon the noxious parasite in his remote retreat. Physicians will hopefully renew their attack on two of the most hopeless maladies they have hitherto been called upon to encounter. One interesting fact emerges from the kaleidoscope of changes that for the last eight years have characterised the history of syphilis. Mercury, the great specific drug in the treatment of the disease, still retains its place as an essential and efficient therapeutic remedy. In spite of the brilliant results obtained by salvarsan, its value is that of an ally and an adjuvant which does not do away with the need of mercury. At this particular juncture, when the conquest of syphilis has so suddenly been placed in the hands of medical science, it is a matter of peculiar interest to have in London Professor Noguchi, whose brilliant work has taught us how to cultivate the *Spirochæta pallida* in artificial media, to make luetin, and has placed on a new basis of scientific fact the study of latency and of the remote phenomena hitherto grouped under the name of parasyphilis.

CURRENT TOPICS.

The Cinematograph in Medical Education.

SOON after the introduction of cinematography it was recognised that this method of illustration could be applied with advantage to the teaching of practical medicine. A successful demonstration was given quite recently by Professor Stirling, in the medical school of the University of Manchester, upon some of the newer applications of cinematography to physiology. A series of interesting and instructive films were shown to illustrate the movements of microscopic animals by a method known as "dark-ground illumination," and to show the protoplasmic movements of amœbæ and of some animalcules which are propelled by means of ciliary motion. The circulating movements of the protoplasmic granules and chlorophyll granules within certain water plants were projected on the screen. The actual growth of the protoplasm of slime-fungi at the circumference of the organism, as well as the remarkable reversible movements in the protoplasm itself, and also the characteristic corkscrew-like movements of spirochætes, were well seen. The latest advance in cinematography, which is known as "Ultra-Cinematography," was illustrated. In this method the successive phases of movement are slowed down. Impressions of a movement, such as walking, running, or the flight of a bird, are taken at the rate of 180 images per second, and these images were projected in the ordinary manner—*i.e.*, at the rate of 16 per second. Illustrations of a man walking, running, jumping, and throwing a stone, as well as the flight of a pigeon, were shown by this method, so that the audience could analyse with ease the successive movements of the human limbs in locomotion, as well as the graceful movements of a pigeon flying freely in the open air. The beating of the heart in the open chest of an animal at its normal rate and during asphyxia was projected—the movements being slowed from ten to twenty times their normal speed so that the successive stages of these movements could be analysed by the unaided eye. The final triumph was reached by the demonstration of the process of leucocytic diapedesis from a piece of spleen removed from a developing chick which had been placed in a sterilised culture-medium and kept at 37° C. The possibilities of this method of education are enormous, for the student is brought face to face, as it were, with the "hidden mysteries of Nature and of Science."

Boric Acid in Sausages.

The self-contained cylindrical breakfast-requisite which forms such an appetising and, when accompanied by mashed potato, such a popular dish, very seldom appears in the courts. For, when well cooked, sausages are most nourishing, and they may be safely recommended as a wholesome diet for all except infants and gouty subjects. Like most prepared meaty foods, some care must be taken to see that only fresh ingredients are employed in their manufacture. Occasionally a moderate quantity of preservative may be necessary, usually boric acid, though this need not be excessive in amount. A farmer was summoned last week at Devonport for selling sausages mixed with boric acid in such a manner as to render them injurious to health. It was stated that the quantity of boric acid present was found to be 0.4 per cent., or 28 grains to the pound. An interesting personal testimony as to the harmfulness of boric acid was given by Professor H. R. Kenwood, who stated, in his evidence, that in 1903 he took ten grains of boric acid at two meals, morning and evening, for three days, and on the third day he suffered from the train of symptoms known to be associated with this drug and called borism—headache, loss of appetite, depression, and diarrhœa. He discontinued taking this drug and was well again in 48 hours. In 1905 he renewed the test, and it produced exactly the same symptoms on himself in three days, and on the morning of the third day, when he left off taking the drug, the symptoms disappeared and he was well in 48 hours. Owing to the fact that it was admitted that boric acid was one of the least harmful of chemical preservatives and that it was a general custom to add these to sausages, the defendant escaped with a nominal fine of ten shillings. The question of idiosyncrasy has always to be considered in dealing with poisoning by small quantities of a chemical substance, for it is quite possible for some people to remain absolutely unaffected after taking a few grains of boric acid which might cause serious illness in others.

Salvarsan in Anthrax.

An interesting case has been reported from Bradford, where many opportunities have occurred for the investigation of anthrax in the wool factories of the district. It appears that a worker named Rothera, æt. 26, contracted anthrax. He was taken to the Bradford Infirmary on September 21st, where three doses of Sclavo serum were administered. As he did not improve, 0.6 of a gramme of salvarsan was injected intravenously. He then improved rapidly, and on September 29th began to take ordinary food. On October 3rd, however, he vomited blood and died in the evening. Dr. Eurich, bacteriologist to the Anthrax Investigation Board in the Bradford District, said that he found the anthrax bacillus present in the lesions when the patient was admitted. A *post-mortem* examination revealed the existence of chronic Bright's disease. After death he failed to find any trace of the original anthrax bacillary infection. He added that the mortality after the Sclavo serum treatment was 9.0 per cent., against a former mortality of 75 to 80 per cent. in anthrax. The case is of great scientific interest as it points to the fact that salvarsan destroys the anthrax bacillus in the tissues. It is somewhat unfortunate that the patient suffered from chronic disease of the kidneys, as the results are thereby complicated. It is, of course, well known that the use of salvarsan is contra-indicated when there is serious organic disease present, and presumably it was not detected in the case of the Bradford patient. It is more than ordinary ill-luck that the case should have occurred in Bradford, as it will naturally prejudice future sufferers from anthrax from consenting to a trial of the drug. Lastly, from all this tragedy issues the fact that salvarsan appears to have cured anthrax when our only other available remedy had failed.

Flies as Carriers of Infection.

The crusade against flies still continues with unabated vigour. Only last week further reports on the investigations conducted at the instance of the Local Government Board into the question of the conveyance of infection by flies was issued. They contain valuable papers by Dr. Gussow on "*Empusa musca* and the Extermination of the House-fly," Dr. Copeman on "Hibernation of House-flies," Dr. Hindle on "Colour Preference of Flies" and "The Range of Flight of *Musca domestica*," and Dr. Graham Smith on "Non-lactose Fermenting Bacilli in Flies." The investigations are summarised by Dr. Arthur Newsholme, Chief Medical Officer of the Board, who expresses the opinion that they possess much general and scientific interest, and have important practical bearings. "The exact share borne by flies in conveying the infection of epidemic diarrhœa," he says, "cannot yet be stated. It would be a mistake, with our present knowledge, to assume that the problem of the prevention of this disease is limited to the destruction of flies. It is concerned also with the personal cleanliness of the mother who has to prepare the infant's food, and with the cleanliness of the house, the backyard, the court, and the street, from which infective material may obtain access to the infant's food, with or without the intermediation of flies. For practical purposes, however, the number of flies in the summer months may be regarded in towns as a valuable index, under present conditions, of the possibilities of contamination of food by pathogenic microbes or by decomposing organic matter, especially in districts in which privies and pail closets persist, and in which accumulations of house refuse or stable refuse are permitted." In Dr. Copeman's paper it is stated that the one specially interesting and unexpected point that emerges from the preliminary investigation into the question of hibernation is found in the fact that not a single specimen of the house-fly (*Musca domestica*) was met with among the considerable number of hibernating flies caught in situations which have hitherto been regarded as its special habitat. "This," he says, "may possibly be accounted for, in part, by the comparatively slight prevalence of the common house-fly during the summer of last year." The conclusion Dr. Hindle draws from an experiment regarding flies and colours is that under the conditions of the experiment flies do not display any marked colour preference, and it therefore seems unlikely that the adoption of any particular colour for the walls of houses and stables will have any effect on the number of flies entering them.

Careless.

The old story again. It used to be sponges, and now it is rubber gloves. Damages have been given against a surgeon for leaving a rubber glove as a *quid pro quo* for a tumour in a patient's abdomen. How it could be done we do not know. Anyhow, it was done. What seems to us rather hard is that positive negligence is punished so much more severely than negative, perhaps because it is much rarer. It is also more easily proved. Still, a man who misses an obvious and curable condition in an abdomen because he does not expect it escapes scot free, while his patient dies, and a comparatively innocuous clip is the cause of more trouble to the man who leaves it lying about than to its receptacle. Nearly everything has been stitched up in somebody, and many men now follow the advice of a famous surgeon who said it was a wise precaution to count one's nurses before closing the abdomen.

The Discovery of a New Vaccine for Gonorrhœa.

If it be true, as reported by the Paris correspondent of a daily newspaper, that the director of the Pasteur Institute in Tunis, M. C. Nicolle, has discovered a more efficacious vaccine for gonorrhœa, a notable advance will have been made in the therapeutics of our art. Hitherto all previous attempts in this special direction have been signalised by ill success, and yet Nicolle claims wonderful results, simply attained, by the vaccine he has discovered. He bases his claim upon two hundred cases, all of which were successful. Three or four injections, intravenous and subcutaneous, were made every two or three days, and cures resulted in less than fifteen days, all pain and discomfort ceasing after the first injection. It is impossible to overestimate the value of such a treatment if further investigation prove the stability of this discovery. The first invaluable advantage which its application suggests is that of the treatment of purulent conjunctivitis, in the child and in the adult, the former of which is answerable for at least 30 per cent. of the cases of blindness in the blind asylums of the world. Preventable as are the results of purulent conjunctivitis in infancy by skilled treatment in the present day, it is still a fact that, through neglect and other causes, the destruction of corneæ still continues by this means to prevail. We are convinced that this regretable fact is partly due to the absence of any standardisation of the treatment of the disease. Almost every ophthalmic surgeon has his own pet method of treating the gonococcal conjunctivitis of infancy. Thus a complexity of methods can only breed confusion in the mind of general practitioners, by whom the cases are first seen. On the other hand, were a standard line of treatment to be laid down, universally accepted and observed, and authoritatively enforced, the cases of loss of vision from this disease would soon become conceivably less. It is from this aspect that an added value would result from the discovery of a vaccine for gonococcal infections. The treatment of purulent conjunctivitis of infancy, of gonococcal origin, would at once become standardised, the confusion of treatment at present prevailing would cease, and every practitioner would have no hesitation in deciding as to the necessary course to pursue. Upon these and other grounds, therefore, in respect to gonococcal infections generally, we may only trust that M. Nicolle's discovery may prove to be *un fait accompli.*

Round the Circle.

The medical profession have from time immemorial believed in the curative powers of waters of natural mineral springs. Every physician had a pet resort, and to it he sent his patients. They came back better, and that was enough. The credit for the cure was given to the waters, for no special reason except that the sick man had drunk them. Then came Osler the iconoclast. He scared us with hot words, pointing out that artificial waters of identical composition with those that flow from the breasts of mother earth must have as effective therapeutic action as their prototypes. Are not Abana and Pharpar, if not better than, at least as good as, all the waters of Israel? This idea was so sensible that we believed it implicitly and still sent patients to Harrogate, telling them that it was not so much the drinking of the waters as the way the waters were drunk that mattered. Now we are back again where we began. When the Curies discovered radium many workers found traces of it in mineral springs. Then Ramsay showed that the wonderful properties of radium are due to the gas niton of which it contains 75 per cent., and further that the springs at Bath and many other places owe their value to the niton contained in their waters. So there we are for the present. We have looped the loop and are back at the point where we started. The field of knowledge is so vast and vague that almost all we can do is to get hold of some statement and prove it and its contradictory alternately. This whirligig action seems rather fruitless; but perhaps a screw propeller is a better and more hopeful simile. In addition to our obvious circling we have a less evident but ever present movement of advance.

Does Ozone Purify the Air.

Some interesting experimental work has been recently conducted by Drs. E. O. Jordan and A. J. Carlson, of Chicago, into the bactericidal and disinfectant action of ozone (*a*). Their results agree with those of Erlandsen and Schwarz, Hill and Flack, and others, with respect to the power of ozone in strong concentration to mask certain odours, such as those of asafœtida, oil of cloves, ammonia, musk, etc., which are certainly made less obvious by the presence of ozone. But in a concentration that masks a bad smell by its own intensive odour, ozone has been shown to cause irritation of the respiratory tract and also fatigue of the special olfactory sense organ. Some bacteria are killed by ozone, it is true, but practically this fact is of little importance, since a similar bactericidal effect could be obtained more efficiently by the use of formalin or some other familiar gaseous disinfectant. If ozone be, to some extent, a deodoriser, it would not be used as a disinfectant,

---

(*a*) *Journ. Amer. Med. Assoc.*, September 27, 1913.

but merely for the purpose of removing the sense of frowsiness in the atmosphere of a closed place. Various devices have been prepared for utilising on the large scale this "freshening" effect of ozone when newly generated, notably on one of the metropolitan "tube" railways. That the installation has had the desired effect no one will deny who compares the present state of the atmosphere in the stations and along the line with what it was before the system was adopted. It is not pretended, of course, that ozone wards off all disease germs, for that would be an extravagant claim which is unsubstantiated by laboratory tests. From the public health aspect it is worth bearing in mind that ozone may conceal faults in ventilation, while it is powerless wholly to correct or counteract them.

The Condition of Dublin.

The labour dispute in Dublin, with the acute distress which it has brought on the poorer classes, does not appear so far, except in the case of children, to have produced much effect on the health of the city. There has not, at any rate, been as yet any undue pressure on hospital accommodation. The incidence of disease and the mortality among children has been unduly high. At the end of a dry summer Dublin children always suffer heavily from diarrhœal diseases, disseminated doubtless by the flies which breed unchecked in the filthy streets, lanes, and courts of the poorer parts of the city. This year, however, there can be little doubt that these diseases are more widespread on account of the distress consequent on the labour troubles. We are glad to know that several of the special relief agencies are devoting themselves particularly to the care of the children, and are providing free dinners in the schools for needy children. It is more difficult, however, to reach the younger infants, among whom diarrhœa makes the greatest havoc. At the time of writing the dispute shows no signs of an early settlement, and the various relief agencies have more scope for work than funds to undertake it.

The Value of Leucocyte Extract in Erysipelas.

A study of the defensive mechanism of the human body has led bacteriologists more and more to devote their attention to the intracellular resisting agents of the blood and other fluids. The researches of Hiss, Allen, Guisser, Alexander Moore, and others show that extracts of leucocytes possess a valuable influence in patients suffering from various acute bacterial infections. Only three years ago Dr. J. G. Dwyer, of New York, published a report of six cases of acute infective processes in the ear, nose, and throat, treated by this means, and recently he and Dr. P. H. Hiss have recorded, in the *Medical Record*, the results of the use of leucocyte extract in erysipelas. The remedy was tried in 148 cases of all types and grades of severity. In every case there was a fall of temperature and a rapid improvement in the general condition following its use. The best effects were observed when the treatment was begun early in the course of the disease, the duration of which was generally shortened, working out to an average of three and one-tenth days. No stimulation was found to be necessary, the leucocyte extract keeping the patients quite comfortable, with a pulse-rate rarely above 90. The authors call attention to the beneficial effect of the extract in post-operative or surgical erysipelas, especially about the eye, ear, nose and throat. Mastoid wounds, for instance, were found to heal in a shorter time than in uncomplicated cases. The extract is prepared, under aseptic precautions, from the leucocytic sediment from the pleural exudate of rabbits which have received intra-pleural injections of aleuronat. The method seems worthy of trial, not only in cases of erysipelas, but also in many other acute infections.

As we go to press we learn with great regret of the death of Sir John Batty Tuke, U.D., D.Sc., M.D., the well-known alienist. We hope to publish a full obituary notice in our next issue.

PERSONAL.

Mr. R. Jones Evans, M.R.C.S.Eng., L.R.C.P.Lond., has been appointed Mayor-elect for Pwllheli.

Dr. Campbell Watt has been elected the first President of the newly formed South African District Surgeon's Association.

Dr. Arthur Deaker Owen has been appointed Medical Officer of Health for the Hampton-on-Thames Urban District.

Dr. John Henderson, M.D., Ch.B.Glasg., F.F.P.S. Glasg., has ben appointed Professor of Medicine in St. Mungo's College, Glasgow.

Dr. George Parker, M.D.Cantab., has been appointed Sole Lecturer in Forensic Medicine and Toxicology at the University of Bristol.

Dr. H. W. Catto, M.B., B.S., M.R.C.S., L.R.C.S., has been appointed Assistant Pathologist and Bacteriologist to the Island Medical Department, Jamaica.

It is announced that Sir David Bruce will leave England on November 1st for the purpose of concluding his sleeping sickness investigations in Central Africa.

Dr. F. M. Sandwith, Gresham Professor of Physic, will deliver the first of four lectures at the City of London School, Victoria Embankment, E.C., on Tuesday, October 28th, at 6 p.m.

Dr. Francis Warner, Consulting Physician to the London Hospital, will deliver the first of a course of lectures on "The Neuroses and Psychoses of Children," on Tuesday, October 21st, at 2 p.m., in the Clinical Theatre of the Hospital.

Sir Thomas Clouston, M.D., LL.D., will deliver the fifth Norman Kerr Lecture on "The Clinical Aspects of the Study of Inebriety" on Monday, November 3rd, at 4 p.m., in the Hall of the Royal College of Physicians, Queen Street, Edinburgh.

Mr. G. H. Makins, C.B., F.R.C.S., has been appointed a member of the Committee of Management of the Conjoint Examining Board of the Royal Colleges of Physicians and Surgeons in the vacancy occasioned by the retirement of Sir Rickman Godlee.

Dr. W. Wright Wilson, of Acock's Green, Birmingham, was the recipient the other day at a gathering of the Provincial Grand Lodge of Mark Masons of Warwickshire, held at Coventry, with a handsome symbolical jewel on his retirement, through ill-health, from the office of Deputy Provincial Grand Master of the Mark Degree.

The work of reconstructing the old operating theatre and of building the Etherington-Smith Memorial Ward for it, the whole forming a memorial to Mr. Etherington-Smith, Warden of the College and assistant surgeon, who died in April last, is now well in progress, and when completed will form a valua addition to the hospital equipment.

FRENCH CLINICAL LECTURE
ON
THE TREATMENT OF FRACTURES OF THE SKULL BY LUMBAR PUNCTURE AND EARLY TREPHINING.

By PROFESSOR LEON BERARD, M.D.,

Surgeon to the Hotel Dieu, Lyons.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

I HAVE already discussed with you in connection with concussion, contusion and compression of the brain, the immediate treatment to be instituted in traumatism of the cranium: complete rest in the horizontal position, warmth, the administration of cardiac tonics, especially by the subcutaneous injection of diffusible stimulants such as ether, caffeine-serum, camphorated oil and so on; careful disinfection of the scalp, as well as of the natural cavities of the face, especially if the traumatism be an open one, and in presence of loss of blood or cerebro-spinal fluid or actual brain substance. In man the scalp should be close shaved. In women, with closed traumatisms we may hesitate to insist upon the sacrifice of this ornament, but unless we do so it will be very difficult to make out the little hæmatomata, the painful spots, the little depressions and the ecchymoses symptomatic of fissures of bone. Pray do not allow a question of æsthetics to weigh in the balance when your patient's life may be hanging by a thread, and if you really have serious reason to suspect fracture of the skull take all necessary steps and have the head prepared as for operation.

On this occasion I shall deal only with fractures of the base of the skull. Even more frequently than with fractures of the vault of the skull fractures of the base not accompanied by any visible wound or depression may fail to be recognised on a first examination. It is only possible to be certain of the existence of this lesion soon after the receipt of the causal injury in rare instances—in fact, only when there has been evacuation of cerebro-spinal fluid *viâ* the nose or ear. The other signs only amount to a probability, the probability being the greater the more of these signs are present. They only supervene later on, in succession, with intervals of hours or even days. To begin with, there is otorrhagia and epistaxis which only possess a diagnostic value when persistent, copious and recurring or when accompanied by escape of cerebro-spinal fluid. Now the escape of this fluid can only be detected after the hæmorrhage has ceased, and the same remark applies to the subconjunctival ecchymosis which comes on in from 36 to 72 hours after the receipt of the injury. Symptoms of paralysis of the cranial nerves may be delayed until the third or fourth day showing steadily increasing pressure upon nerves.

Now, this period of latent or slight symptoms is the most dangerous one of all. When the victim of the accident has escaped the rapidly fatal effects of bulbar concussion and extensive contusion of the brain, he is still exposed to the risk of death, or, at any rate, of grave disturbances, by rapidly progressive compression of the brain consequent upon intra- or extra-dural bleeding, by absorption of the blood in hæmolysis which will irritate the nerve centres and, lastly and especially, infection of these centres and their meninges starting from the places where the fissure traverses the nose, ears, etc., which are always sources of infection.

It is therefore of the greatest importance to make a trustworthy diagnosis as soon as possible, and to institute adequate treatment. Of all the means of investigation which allow of a rapid diagnosis and suitable treatment of fractures of the base, one of the best, one on which the greatest hopes are founded, is exploratory lumbar puncture. Tuffier and Milian proclaimed that this puncture always gave issue to blood-stained fluid in cases of fracture of the base. When made some hours later the fluid may be merely yellowish or pink, the latter being due to blood pigment. Culture of this fluid would enable us to tell whether or not there was infection of the fracture and therefore of the meninges. Tuffier, however, had already called attention to the possibility of blood finding its way into the needle and so into the fluid during puncture, hence he advised collecting the fluid in three portions and making sure that the three specimens all presented the same reddish or pink colour. He even added that there might be fracture without coloration of the fluid if the bleeding happened to be slight so that a negative result did not absolutely dispose of the possibility of fracture having taken place.

In 1902, Boutier, of Paris, selected this as the subject of his thesis, and arrived at the conclusion that this method of exploration could not be relied upon to furnish early, trustworthy proof of the existence of such fractures, because a fracture might have taken place without any coloration of the fluid; also because the fluid might be blood-stained in the absence of fracture in cases of cerebral contusion and intra- or extra-dural hæmorrhage The elements of blood may even be present in cerebro-spinal fluid apart from traumatism, as, for instance, when in cerebral hæmorrhage the blood finds its way into the ventricle, also in cerebro-spinal meningitis.

It follows that the presence of blood in the cerebro-spinal fluid only possesses a diagnostic value when other symptoms all point to the same conclusion. According to Boutier, puncture is only indicated in cases of injuries to the head, accompanied and followed by loss of consciousness or delirium in respect of the causation of which no information is forthcoming.

We have shown that this sign is not certain, neither is it early. After even extensive fractures of the base the meningeal hæmorrhage is usually not very free and the blood may not find its way into the fluid for from 12 to 36 hours. With regard to prognosis, Boutier does not think that there is any necessary relationship between the gravity of the traumatic lesions and the depth of coloration of the cerebro-spinal fluid, but he admits that bacteriological examination of the fluid does enable us to ascertain whether or not the fracture is infected.

It is not only in fracture of the base that lumbar puncture gives inconstant results. Henschen and Lenormant have pointed out that, in opposition to what we might anticipate, grave cerebral contusion, extra-dural, or even intra-dural effusion of blood may exist without any coloration of the fluid. Everything depends upon the freedom of communication between the sub-arachnoid spaces and those of the brain and cord.

Are we, then, to conclude in favour of abstention from lumbar puncture in traumatisms of the cranium? Certainly not, because, when done with proper aseptic precautions, it is practically free from danger, and though it may leave us in doubt as to the precise lesion when the fluid is blood-stained, the withdrawal of several cubic centimetres of fluid almost always determines improvement in the patient's state. For instance, the coma promptly clears up, the violent headache and restlessness quiet down in a few hours, because the puncture has relieved the pressure of the blood-laden fluid in the subarachnoid spaces, or because it arrests irritation of the nerve centres by effused blood.

Muret advises puncture as early and as often as may be required, every two or three days for a week or two, taking care to avoid too sudden decompression. As a rule the quantity withdrawn is from 15 to 30 cc. Of nine cases of fracture of the skull in Quénu's wards nine recovered.

Chiarugi, of Sienna, claims that lumbar puncture almost always yields positive results by revealing the presence of blood-stained fluid, and he holds that it is an excellent means of diagnosis in slight cases with ill-marked symptoms. As a means of treatment it is valuable because in slight cases the first puncture puts an end to the vertigo and headache, while in fracture it relieves the intra-cranial pressure, decomposes the nerve centres and favours consolidation of the bone by preventing blood and fluid being forced through the fissures. In cases where surgical intervention is indicated previous lumbar puncture improves the pulse and respiration.

In opposition to the sturdy advocates of lumbar puncture, there are surgeons who deny that it can have any decompressive or antiseptic action, and urge that in any case its action is very fugitive. When frequently repeated it necessarily exposes the patient to some risk of infection, and, on the other hand, it cannot act directly on the hæmatoma which is pressing upon the brain. Cushing, and Vincent, of Algiers, at about the same date (1908) advocated treating all cases of fracture of the base by trepanation and drainage, because even when they appear to be closed these fractures are in reality open since they communicate with the nasal and ear cavities which are always more or less infected.

Vincent advocates this treatment, especially as a means of averting meningo-encephalitis by allowing the microbial elements and toxins in the bony focus to escape as they are formed instead of multiplying in a closed cavity. In June, 1912, Vincent brought forward eight cases thus treated, all of which recovered.

Trephining is naturally more efficacious when performed early, as soon as the effects of the concussion have passed off, or even during this period should the shock be prolonged with presumptive signs of fracture of the base. If the injured person is in coma no anæsthetic is required, provided we previously raise the blood pressure by an injection of caffeine in normal saline solution or of camphorated oil. It may, however, prove the means of obtaining unhoped-for recoveries even after two or three days when meningo-encephalitis is apparently already in being, to judge from the restlessness, the contractures, the stiffness of the neck and the rise of temperature. This is also the case when the existence of encephalo-meningitis is confirmed by puncture giving issue to a turbid fluid under pressure containing polynuclear cells and microbes.

I, too, could relate cases of recovery after trephining for fracture of the base operated as late as the fourth day in presence of meningo-encephalitis, but I am fain to admit that in several cases early trephining did not avert a fatal result, either because my intervention was not on a sufficiently large scale or because I only operated on the fractured side. We must bear in mind that one of the elements of gravity in these cases, especially after grave injury or falls from a height, is extensive, deep contusion of the brain which *per se* may determine irreparable lesions of the brain and medulla culminating in rapid death, trephining or no trephining.

To sum up, then, I would advise that in all cases of fracture of the base, obvious or only suspected, lumbar puncture should be performed with the usual precautions, never withdrawing more than 30cc. of cerebro-spinal fluid. Whether the fluid be red or not, if there be a copious discharge of blood or cerebro-spinal fluid from the nose and ears, with other signs of basic fracture, such as paralysis of the facial or external oculo-motor nerve, especially when the circumstances are such as to allow of trephining under surgical conditions, then we ought to perform free, bilateral, subtemporal trephining with drainage of the subarachnoid spaces. Failing this intervention, puncture is to be repeated as often as the symptoms seem to require (headache, stertor, somnolence and extension of the paralysis). We must bear in mind, however, that puncture, even when effectual, is at best of ephemeral benefit. Useful, no doubt, in relieving disturbances due to concussion and slight contusion, it can do nothing to mitigate the compression effects of free hæmorrhage, nor can it be relied upon to cut short meningo-encephalitis already in being.

A few pessimistic words in conclusion. Every person who has sustained an injury of the skull, whether he recovers, with or without operation, whether he gets well soon or drags along a tedious convalescence, must be looked upon as a fragile subject, whose professional capacity will nearly always be diminished. Remember that there are intra- and extra-dural hæmatomas which, after an interval of quiescence of from two to ten months may, in the course of a few days, determine fatal compression should the subject not be within reach of a surgeon. These patients require to be kept under observation, and they must be urged to take it easy for some time to come. After the expiration of the period of temporary incapacity that of tertiary, post-traumatic troubles is only beginning, and it will extend far beyond the three years set apart for possible revision under existing legislation. At any moment we may be confronted by disastrous developments, as trying to the surgeon as they are menacing to the patient.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Arthur E. Giles, M.D., B.Sc., F.R.C.S., Surgeon to the Chelsea Hospital for Women; Gynæcologist to the Prince of Wales's General Hospital, Tottenham. Subject: "Pessaries versus Operations in the Treatment of Uterine Displacement."*

We are requested to announce that the demonstration of the parasite of rabies and of the cultural researches upon spirochætes by Dr. Hideyo Noguchi, of the Rockefeller Institute, New York, which was to have taken place on Monday last, has been unavoidably postponed until Monday, October 20th, at 5.30, at the Royal Society of Medicine, 1 Wimpole Street, W.

The new King's College Hospital, at Denmark Hill, S.E., which was formally opened by the King in August last, was opened for the first time on Monday for the reception of casualties.

ORIGINAL PAPERS.

STATUS LYMPHATICUS IN ADULTS, ITS CLINICAL DIAGNOSIS AND IMPORTANCE. (*a*)

By HAVEN EMERSON, M.D.,
New York.

At the present time our knowledge of the condition recognised as status lymphaticus, or as it is more commonly called by German writers—status thymico-lymphaticus, is not based on ætiology, but upon physical characteristics.

It is not essential to the pursuit of clinical studies that we should have a theory of the disturbed physiology, which determines the abnormal physical individual, nor yet await the complete understanding of the separate or mutual functions of the various secreting tissues, before we admit the relation of the clinical findings to health and disease. What is important for the internist, and for the eugenist, is the recognition of a type of individual whose physical peculiarities seem to bear an important relation to his mortality, in certain infectious diseases, and to his susceptibility to some of the deteriorating influences which modern society tolerates or suffers from. This recognition of a type of person, who may not appear less healthy or less capable than the rest of society, is at present based wholly on physical examination, one may almost say, on inspection alone.

Inspection of the human body provides us with physical signs of health or disease upon which we rely. The value of physical signs, in relation to health and disease, depends upon the constancy of association of the observed facts during life with a definite series of findings after death. If the physical examination reveal constantly certain variations from the usual, or the accepted normal, and if the *post-mortem* examination reveal a constant series of gross and microscopical abnormalities in a tissue or groups of tissues, then where these two sets of observations are noted in a high per cent. of cases among those dying of certain of the infectious diseases, we may presume that there is some causal relation between the physical findings and the mortality of such individuals. From the time when Paltauf (1889-90) pointed out the pathological symptom complex of status thymico-lymphaticus, pathologists have more and more generally verified his observations and in some instances have added to the data he gave in defining the condition found *post-mortem*. When Neusser (1911) gave an equally clear description of the clinical picture of status thymico-lymphaticus, an impetus was given to observations by the internists, to test their skill in establishing a reliable clinical diagnosis with the possibility of its bearing upon the prognosis or treatment of various diseases. Having watched the cases of meningitis, typhoid fever, and septic infections in the general medical wards of Bellevue Hospital die apparently in a high per cent. of cases when they showed the physical marks of status lymphaticus, and having noted at the autopsy table the constancy of pathological findings which confirmed the clinical description of such cases, I wished to test the reliability of the various criteria given for the recognition of a characteristic or classical case of status lymphaticus.

The material upon which this study was based was at my disposal while attending the alcoholic wards at Bellevue Hospital in New York. These wards receive patients suffering from the toxic effects of alcohol and of other narcotic drugs, cases of attempted suicide, and sick prisoners. Among the admissions are often to be found border-line cases, which on further study prove to be psychopathic cases rather than toxic individuals of normal mentality. One thousand cases were studied, five hundred consecutive male admissions in July and August, 1912, and an equal number in January and February, 1913.

The record of each patient consisted of the following points:—

Age; country of birth; cephalic index, based on the occipito-frontal and biparietal diameters; the colour and physical qualities of the hair of the head; the amount of hair upon chin, the upper lip, on the chest in front, in the axillæ, and the amount and distribution of pubic hair; the amount of faucial, lingual, and pharyngeal lymphatic tissue, observed by inspection and digital palpation; the presence of palpable cervical, axillary, and inguinal lymph nodes; the shape and proportions of the neck, thorax, abdomen, thighs, and upper arms; the details of the external genitals; the general nutrition; the presence of congenital anomalies; the clinical diagnosis.

Of the 1,000 cases examined, 780 were without any stigmata or physical characteristics which would mark them as abnormal.

Two hundred and twenty showed most, if not all, of the physical attributes sufficient to identify them as cases of status lymphaticus.

Analysis of the records of these two groups shows certain facts.

As to age it was found that 18.63 per cent. of the status cases were under 30 years, while but 9.66 per cent. of the normal cases were under 30 years. Above the age of 30 the distribution of the status and the normal cases showed such slight discrepancies as to lead to no conclusions. The cases ranged from 19 to 84 years.

As to nationality or race the variations in the two classes were negligible. Eighteen nationalities were represented.

As to cephalic index, if we use the term dolicho-cephalic to represent an index of 80 or less and brachy-cephalic for an index of over 80, we find that the cases of status are almost equally divided, while the normal cases show a preponderance of 7 per cent of dolicho-cephalics.

	Status Lymphaticus.	Normal Cases.
Dolicho-cephalic,	49.14 per cent. ...	53.63 per cent.
Brachy-cephalic,	50.86 per cent. ...	46.37 per cent.

In noting the colour, texture (*i.e.*, fine or coarse), lustre, curliness or straightness of the hair of the head, no differences of any importance were noted; the beard was noted as being scanty in 9.87 per cent. of the normal cases, but scanty or wholly lacking in 57.22 per cent. of the status cases. Similarly it was found that the moustache was scanty in but 7.94 per cent. of the normal cases, but scanty or lacking in 55.90 per cent. of the status cases. Sternal or anterior thoracic hair was found to be scanty in 41.15 per cent. of the normal cases, and scanty or wholly lacking in 89.54 per cent. of the status cases. The axillary hair was scanty in 13.45 per cent. of the normal cases, but scanty or absent in 65.45 per cent. of the status cases. The pubic hair was found to be of the feminine type (*i.e.*, arranged transversely and not rising towards the umbilicus but ceasing abruptly above the pubic region) in 13.20 per cent. of the normals, and in 95.90 per cent. of the status cases. The faucial, lingual, and pharyngeal tonsillar tissue was found increased in amount in the normal cases in 6.66 per cent, 26.02 per cent. and 4.48 per cent.

(*a*) Paper read in the Section of Medicine before the International Congress of Medicine, London, 1913.

respectively, and in the status cases in 7.27 per cent., 23.18 per cent. and 0.90 per cent. respectively; not notable differences except in the case of the pharyngeal tonsils. Even though the pharyngeal tonsil seems to be enlarged five times as often among status cases as in normal men, the percentage of incidence is too low to use for diagnostic purposes.

The case of the superficial lymph-nodes is somewhat similar, for although the cervical, axillary, and inguinal nodes are found palpable in somewhat higher proportion of cases in the status individuals than among normals, the occurrence of such palpable glands is so common as to allow of no diagnostic application of this point. In normal cases the cervical, axillary, and inguinal glands were palpable in 15.25 per cent., 33.33 per cent., and 53.71 per cent. of cases respectively, and among status cases in 25.90 per cent., 41.81 per cent., and 55.90 per cent. respectively. The neck was noted as long and slender in 32 per cent. of normals and in 36.81 per cent. of status cases—an unimportant difference. The thorax was found long and narrow in 27.94 per cent. of the normal cases, and in 44.09 per cent. of the status cases. The contour of the abdomen as to its roundness or flatness showed no difference worth noting between the two classes. The thighs were noted as rounded in 30.52 per cent. of the normal cases, and arched in 13.97 per cent. of the normal cases, while in 75.46 per cent. of the status cases they were rounded and in 50 per cent. were arched. These terms, rounded and arched, are used to express the impression made by the difference between the masculine and feminine types of thigh, the rounded as contrasted with the flat thigh being characteristic of feminine physique, and an outward and forward bowing or arching being a feminine attribute as distinguished from the straighter masculine thigh. In the case of the upper arm it was found that 25.76 per cent. of normal cases were described as having rounded arms, while among the status cases there were 75.90 per cent. with this feminine characteristic. Among the normal cases the penis was noted as small in 22.56 per cent., while this was the case among the status cases in 51.83 per cent. The glans penis was noted as small in normal cases in 26.03 per cent., and in status cases in 54.54 per cent. The shape of the glans was described as pointed or acorn-shaped in normal cases in 32.05 per cent., and in status cases in 61.31 per cent. There were no undescended testicles among the normal cases, but there were six cases or 2.7 per cent. found with undescended testicles among the status cases, 4 with both undescended, 2 with 1 undescended. The size of the testicles was noted as small in 24.74 per cent. of normal, and among the status cases in 45.90 per cent.

As to general nutrition there were no differences of any moment.

Congenital anomalies were found in 0.25 per cent. of the 780 normal cases, and in 3.63 per cent. of the 220 status cases.

Complicating medical affections in addition to drug addiction were found in 3.58 per cent. of the so-called normal cases, and in 10.40 per cent. of the status cases. 94.4 per cent. of all cases were admitted for alcoholic intoxication.

To summarise the data obtained from these examinations, it may be said that 22 per cent. of the particular class of men representing chiefly the alcohol and narcotic drug habitués, show sufficiently striking variations from the usual masculine physical habit to be classed as cases of status lymphaticus; that, of the points usually noted in arriving at a diagnosis, the ones found to be constant enough to be entitled to consideration are, scantiness or absence of hair on lip, chin, and in sternal and axillary regions, together with the feminine type of distribution of pubic hair with or without scantiness of pubic hair; a tendency to narrowness and length in the thorax; a noticeable roundness and arching of the thighs, and roundness of the upper arms; small size of penis; smallness and pointed shape of glans penis and smallness of the testicles.

In addition, there is a physical character noted in a very large proportion of the cases, and present almost invariably when the points above summarised are also present—namely, a particularly velvety or fine and delicate texture of the skin which is seen and felt to be almost wholly free from the usual short hairs to be found commonly, for instance, upon the thigh in men. For lack of such terms as would accurately designate this quality of the skin, I have not made a record of its appearance in the cases above reported, but I wish to call attention to this as an important diagnostic point.

Of the points described by others as commonly noted in cases of status which I find of little or no value in arriving at a diagnosis are, the physical characters of the hair of the head, which is supposed to be commonly coarse and straight in status cases; the faucial, lingual, and pharyngeal lymph tissue, which is supposed to be commonly increased; the superficial lymph nodes, which are supposed to be felt in a high proportion of status cases; the slender columnar neck and the rounded feminine abdomen which are reported as being usual in status. In addition there is a point, described by European observers, which I have so regularly failed to make on physical examination of status cases, and which has so little foundation in the experience of the pathologists at Bellevue Hospital, that I have not made it a part of my records—namely, the spleen. The spleen is supposed to be large in status. This I do not find to be the case. I am permitted by the Director of the Pathological Laboratory to quote from the forthcoming hospital report the results of autopsy records of status since 1905. Of the 3,600 autopsies, 288, or 8 per cent., were cases of status lymphaticus. Of these 288 cases 29.66 per cent. were recessive cases, as shown by microscopical as well as gross study of the lymphatic tissues of the body, and 70.33 per cent. were active cases. Twenty-six of the 288 cases (or 9.20 per cent.) were not associated with other demonstrable lesions as a cause of death.

Two hundred and sixty-two (or 91.08 per cent.) were associated with other lesions. Of these 262 cases, 242 were associated with infectious diseases. Epidemic, purulent, or tuberculous meningitis, typhoid fever, lobar pneumonia, acute and chronic pulmonary and general miliary tuberculosis, acute and chronic cardiac infections, septic infections of a variety of origins.

It is to be particularly noted that of the autopsied cases of typhoid fever 23.07 per cent. were status. Of acute infective endocarditis 19.51 per cent. were status, and of epidemic cerebro-spinal meningitis 48.27 per cent., while of the autopsied cases of lobar pneumonia 2.96 per cent. were status; of tuberculous meningitis 3.80 per cent. were status; of acute and chronic pulmonary or general miliary tuberculosis 4.50 per cent. were status.

In arriving at a pathological diagnosis at *post-mortem* the essential points to be observed in addition to those accessible to the clinician during life, are the gross and microscopic appearance of the blood-vessels, particularly the aorta, which is small, soft, and elastic; the intestinal lymph adenoid tissues, the Peyer's patches and follicles, and the mesenteric lymph nodes which are uniformly found enlarged; either a hyperplasia of the lymph follicles of the spleen in active cases, or fibroid tissue tufts which have replaced previous hyperplasia of the lymph follicles in the recessive cases; enlargement of the thymus gland out of proportion to the age of the subject in active cases.

It is true that percussion and possibly X-ray examination will, in the hands of a few, elicit the presence of an enlarged thymus in children, but the likelihood of this decreases with every decade of the patient's age above the first. By deep digital palpation in the episternal notch the normal aorta can usually be appreciated at each systolic impulse, and this is rarely the case in status cases, owing to the small size of the aorta, but this is of little reliability in arriving at a diagnosis.

For the present it seems to me that a diagnosis of status lymphaticus is justified, when we find, in the case of a man, a decided scantiness of hair on chin and upper lip, scanty axillary and sternal hair, scanty or feminine distribution of pubic hair; the slender thorax; rounded contour of upper arms and thighs with an arching of the latter; hypoplastic external genitals, particularly if associated with cryptorchismus; and a delicate velvety skin. The diagnosis is further confirmerd if we find hyperplasia of the lymph tissue of nose, throat, and tongue and an increase in the palpable cervical and axillary lymph nodes.

If we admit the justice of such a diagnosis, because of the confirmation of a sufficient number of cases verified *post mortem*, of what service will this prove in the practice of medicine?

The obvious and justifiable conclusion at present is that such individuals are more susceptible to the dangers of infectious diseases than are normal people. To avoid for such people by all precautions, especially by artificial immunisation, as for typhoid, diphtheria, and meningitis, every chance of infection, is our evident duty. They are poor risks in an epidemic, and the prognosis for them, when they are infected, is more serious than for normal men. As they have passed the particular dangers of their state during childhood, by especial care or good fortune, so, during maturity, they are among those who cannot be expected to survive, as well as normal men, extreme fatigues, shocks, loss of blood, abuse of narcotic drugs, or surgical procedures. Those physicians whose hospital experience is mainly with people of the upper walks of life will undoubtedly find that the incidence of status lymphaticus is far below the figures I have presented here for alcoholic patients. And in the general medical wards of Bellevue Hospital, which receives almost exclusively the pauper class, the incidence is less than a quarter of that found among alcoholics.

Among psychopathic cases, particularly those who suffer acute alienation in the first three decades, the incidence of status is, I believe, even higher than among the cases I have reported above.

It should by no means be understood from this that all cases of status lymphaticus are undesirables socially, as they may be physically less capable in the struggle for existence than their fellows, for it is in the experience of all who observe these cases that there are among them leaders in scientific and artistic professions, and men of the highest standards of character.

For the identification of status lymphaticus among women we rely upon the peculiar character of the skin of the body and extremities, the scantiness of the axillary hair pad, the scantiness of pubic and perineal hair, hypoplasia of the genital apparatus, and particularly slender thorax and extremities. Some women of decided status conformity have a marked growth of hair on the face and upper lip. As has been pointed out by Paltauf, Bartel, and others, the status cases among women are in a high percentage of cases subject to the dangers of pregnancy and the puerperium. With this addition, what has been said of male status cases applies equally to women.

While we await the embryological, or physiological, explanation for this particular physical habit (lymphatismus, hypoplastic constitution, constitutional inferiority, status thymico-lymphaticus, or status lymphaticus), there is much which the clinician is equipped and particularly fitted to discover as to the relation between status lymphaticus and the incidence and course of various pathological states.

In closing, let me gratefully acknowledge my debt to Dr. Charles Noris, Director of the Pathological Laboratory at Bellevue Hospital, who was the first in the United States to recognise the clinical picture of status lymphaticus in adults, and place its diagnosis upon a sound basis for clinician and pathologist. Without his experience and records of the past seven years I could not have prepared this paper.

SHOULD THE STATE INSTITUTE A NECROPSY IN EVERY CASE OF DEATH? (a)

By J. C. McWALTER, M.A., M.D., D.P.H., LLB.

WHAT happens when we write a certificate of the cause of death? We make a statement of fact—or supposed fact—that a certain person died on a certain day—and a statement of opinion—that he died, say, of heart failure or cerebral hemorrhage. The statement of fact may be quite erroneous—we do not, in fact, guarantee that the man is dead—we certainly are not compelled to ascertain the fact of death. This is bad enough in a document which is taken seriously; but what is the value of the "opinion as to the cause of death"? The practitioner gives it, of course, to the "best of his knowledge and belief"; but he certainly has not "knowledge" of the cause of death, and in most cases his belief is vague, wavering and unsubstantial—if not quite conjectural. In the certificate the practitioner makes eight statements of fact—only one of which may be within his knowledge—and that one statement is so hazy as to be worthless.

Thus you say, in the certificate, "I hereby certify that I attended"—but when? You are supposed, probably, to have attended him in his last illness—but what does that mean? You may have seen a man six months before his death, suffering from tuberculosis or heart disease. You think it highly probable he may since have died of the disease—it is possible that his last illness was tuberculosis or heart trouble, and that you were the last practitioner who saw him—but, surely, your certificate will be a mere guess if you give it.

Again, you state—"I last saw him ——" This is really the only part of the certificate you can make a clear statement about, but you are not asked to say whether you saw him alive or dead.

Further, you say "that he died," adding, perhaps, "as I am informed." Clearly you are not prepared to state the fact of death in a certificate of its "cause." We had in Dublin not long ago an instance in which a doctor gave such a certificate. On the strength of it the death was duly registered and insurance money drawn. The alleged corpse complained at the wake that he did not get his proper share of the proceeds, and the case came into the courts.

(a) A Paper read at the International Congress of Medicine, in London, August 13th.

Another statement of fact you make is that he died on such a day. Obviously, if you are not sure of the fact of death it is futile to specify its date.

Again, you state he died "at——," but you may never have been in the house. You, perhaps, saw the patient at the dispensary, or in your surgery, or elsewhere. He may have died in the street, or in another house.

Then you have to express your "knowledge" as to the cause of his death—of which, by hypothesis, you have no knowledge at all, as well as your belief not only in the cause of death, but in the duration of his illness. You may be completely at a loss to know of what the man really died, you may have seen him but once, but you are bound to put down some cause or other.

To show how certain practitioners regard this document a case may be quoted which occurred in London during the current month. A certain doctor certified the cause of death as chronic rheumatism, whereas it seems to have been a well-marked case of tuberculosis. His reason was that he took the word of the relative, having forgotten about the case. "People say anything to get a certificate," said he in excuse. "The mere fact of something being on the certificate, which is not a medical report, does not mean that he had got that complaint."

The whole edifice of preventive medicine—which probably now costs £24,000,000 a year—the whole basis of the treatment of disease in 40,000,000 of British people—is based on deductions drawn from certificates made up in this manner, and sent on to the Registrar-General's Departments.

We know that the value of statistics from death certificates is further impaired—if possible—by the fact that in a large proportion of cases no medical practitioner has been in attendance. A further large proportion are worthless from various symptoms, as dropsy, hæmorrhage, convulsions, etc., being reported as causes of death.

My ignorance may be denser than that of most practitioners of medicine, but I may be permitted to quote my own experience. I find that I have signed in my time considerably over a thousand death certificates. I have no special reason for doubting that these persons were really dead—but not in two per cent. of the cases did I see the dead body. Not in ten per cent. of the cases did I visit the patients—they mostly called at my surgery. In all these cases there were not more than ten autopsies—and in most of the cases where an autopsy was performed my diagnosis was wrong.

Now, the returns of the Registrar-General are made up of my thousand of supposed causes of death—perhaps wrong nine times out of ten—and of the various thousands of "causes" of other practitioners. But of what value are deductions based on instances which may be more often wrong than right?

I brought this report before the Berlin Health Congress, and suggested that 80 per cent. of certified causes of death were probably erroneous. Sir Clifford Allbutt, who was in the chair, requested an American doctor who was a delegate to the Congress, to give us the benefit of his experience in that Continent. This gentleman, who had an official post in this connection, stated that in America it was considered that what a man died of "was his own affair," but he thought that to suppose that 20 per cent. of death certificates were accurate was probably 50 per cent. too high an estimate. It seems they do things better in France. Bertillon has been at pains to draw some useful inferences as to the causes of disease by comparing the British Death and Disease Tables with the French. It appears that the British tables, in completeness and convenience, have many advantages. This is only departmental work, which we may assume is well done, but if the documents on which all our statistics are based are so loosely written, conjectural and inaccurate as not to represent realities, all the care of the Registrar-General's department, and all the money spent on it, are in vain.

The Paris method is this—A certain number of doctors in each quarter are recognised officially to certify deaths. When a death occurs of which no official information is otherwise available, one of these doctors is notified by the police to attend and ascertain the fact and cause of death. For this he gets a fee of three francs. If there appears to be a necessity for a *post mortem* examination other steps may be taken. Obviously the French are on the road to correct statistics.

Dr. W. A. Brand has recently commented on the drawbacks of the Coroner's inquest. It need not be denied that its defects are many. It is not a court of justice, but it has all its defects. It is in practice bound by rules of evidence which often prevent the discovery of facts. In practice it is a preliminary inquiry—not to find the cause of death, but to find who was to blame. Most of its time is taken up in the discussion of questions which arise under the Workmen's Compensation Act, or in some effort to impose a liability which the other side repudiates. The actual pathological condition which gave rise to death is almost overlooked and obscured in such a welter of opposing interests, but, after all, our knowledge of the cause of death would be much more incomplete were it not for an occasional Coroner's inquest.

Do I, then, advocate that the State should institute a necropsy in every case of death? Certainly. It is the only possible means to ascertain what people really die of. If we do not know what people die of we cannot hope rationally to prevent or treat disease. The Insurance Act gives every person a vivid financial interest in the prevention of disease. Such questions are not merely for the medical societies—they are table talk, train talk, town talk.

It will be said that the current of public opinion will be against mutilation of the dead. It may be thought that more education is still needed—but public opinion will rapidly come round. The last service that any of us can do for our fellow-men is to deliver our bodies to the interest of science and humanity. The public is now infected with an active anxious desire to know what each person dies of—whether it could have been cured, and whether the doctor can be blamed. A mother or father of a family will soon be reconciled to a *post mortem* examination of a child if doubtful points as to its disease can be cleared up. Insurance societies will clamour for reliable data as to the incidence of disease—for they have suffered greatly for want of trustworthy statistics.

When I speak of the State instituting an examination of the cause of death, I do not advocate a system of State examinations. The ordinary attendant might be compelled to state the fact and cause of death, and he should have power to make such a necropsy as seemed necessary—due regard being had to people's feelings.

The services of expert pathologists should be available where required, and these might very well receive a Government subsidy. Where the friends could not pay, a small fee should be available for the official death certificate. In Paris, as we see, the sum paid is three francs.

An immense uplifting would be given to the practice of medicine by any such system of certification. Men could no longer defer a diagnosis and treat the patient symptomatically; they should ever be keen and alert, knowing that any blunders would be sure to be made known. The benefit to the community would be even greater, and pathological science would be enormously enriched. Medicine, at length, would cease to be a mere juggle with the patient.

SOME NOTES ON
ARTHRITIS DEFORMANS,
WITH AN ANALYSIS OF FIFTY CASES TREATED BY MEANS OF CONTINUOUS COUNTER-IRRITATION.

BY W. J. MIDELTON, L.R.C.P., M.R.C.S.

IN the following record of cases it will be found that females predominate to the extent of 39 to 11.

The approximate commencement occurred between the ages of 10-20, 1; 20-30, 11; 30-40, 12; 40-50, 11; 50-60, 13; 60-70, 2. Forty-four have been placed under the heading of rheumatoid arthritis, six osteo-arthritis. Personally I find some difficulty in a number of cases in drawing the line between them, and I agree with the view that the most reasonable distinction is between joints which are merely affected by the toxins of micro-organisms and products of imperfect digestion, and those in which the actual germs themselves have invaded the joints and are causing destruction of cartilage and hypertrophy of the edges of bones.

The subject is still so much a matter of conflicting theories, I prefer to refrain from expressing decided convictions, except that I firmly believe in all cases the toxins responsible for the disease have invaded the brain, spinal cord, and their membranes, and set up changes that lead to a train of symptoms such as:—muscular wasting, cramps, local asphyxias, anæmias, etc. Even the joint changes, I believe, are partly due to impaired nerve influence. The views of Ord, Senator, Spender, P. W. Latham, Ll. Jones Llewellyn, C. J. Macalister and others on this point are well known.

For this reason I always bear the nervous system well in mind when treating these maladies, and employ as the title indicates, continuous counter-irritation in the neighbourhood of the spinal cord.

There are three principal methods of carrying this out:—

1. The blister, followed by savin ointment.
2. Acu-puncture, with counter-irritant drugs such as cantharides, croton-oil, methyl salicylate, oil of mustard, etc.
3. The actual cautery. For this I prefer the galvano-cautery.

I consider the first two the most efficacious on account of the exudation which takes place. The third is good and has the merit of rapid and cleanly application, no dressing being required. All three may be applied with advantage to the joints, as well as to the spinal cord.

The objections raised by those who have no real practical experience of the remedies are, in my opinion, grossly exaggerated. If carefully carried out the pain and discomfort are very slight, and not to be compared to that experienced after many surgical operations. Patients of all ages have undergone treatment by one or other method, or a combination of any two or all three. Some have been extremely feeble, and yet a real disaster has still to be recorded as being due to either as far as I know.

I have found it difficult to understand on what grounds the danger of cantharides carefully employed externally is based. Personally I have never seen any sign of serious impairment of the kidneys in any of my cases in which this has been done. A few have complained of temporary strangury, but this has been readily relieved. Such comparative trifles should not weigh against the great benefits that undoubtedly follow the use of these remedies. It is doubtful if any others offer superior advantages, not excepting vaccines; certainly not in advanced cases.

The *technique* is simple, and although bacteriological investigations, blood tests, etc., may be advantageous in some ways, they are not essential. Let me say, however, that no medical man should treat cases by such means until he has been carefully instructed in their use, and has familiarised himself with certain apparently trifling and yet very important details, otherwise it is not fair to the patients or the remedies. Moreover he should not presume to express a decided opinion until he has treated at least ten cases strictly in accordance with the rules laid down and for a sufficient length of time. I lay great stress on this point. Great patience and perseverance are necessary. I worked hard over one case for more than a year before any really satisfactory result could be shown. Now I am glad to say the improvement is obvious to anyone. Some sceptics say that in such a case the patient got well anyhow, and the remedy had little to do with it. I can only say I do not think so, and the notes of cases appended should go far to prove the value of these methods. In the majority of cases blistering the spine was relied on principally. I prefer not to use the word cure, they are therefore divided into four classes.

1. *Greatly improved,*—*i.e.*, a practical disappearance of all troublesome symptoms, and the acquirement of ability to lead an active life. Twelve.
2. *Much improved.* The pain, swelling, cramp, etc., gone. Ability to use the limbs with sufficient power to carry on household duties, business or pleasure not involving great or prolonged muscular exertion. Nineteen.
3. *Distinctly improved.* General health restored, able to walk a little, use the hands in conveying food to the mouth, move the head freely, etc. Thirteen.
4. *No improvement,* applies chiefly to muscular power and the movement of joints. The general health is almost invariably improved. Six.

The patients, with few exceptions, have come to us after having been treated for years by such means as natural spa waters, baths of many kinds, massage, electricity, exercises, ionisation, residence in Egypt, etc., without lasting benefit. Whereas by means of the blistering or Pyonex treatments patients may be kept going from bad to good and from good to better instead of drifting from bad to worse.

Although dating from remote ages, the revival of these remedies actively, and the present modifications, are comparatively recent; nevertheless I have had the opportunity of watching several cases during long periods, and have noticed them in better health and more active from 2 to 5 years after first being seen and treated by me. No matter how wasted and helpless they may be, it is worth while giving them the benefit of these remedies. Joints apparently ankylosed may become supple, muscles wasted to mere shreds enlarge and become more powerful, veins narrowed down to threads enlarge and become more prominent, attenuated bones thicken and become less brittle, harsh scaly skin may become supple and smooth. Sleep, appetite, digestion and the action of the bowels improve. Pain of all kinds, even headaches, either goes or is greatly relieved. This applies also to cramps, local sweatings, asphyxias, anæmias, morbid flushings, etc. In several instances the power to perspire has returned after having been lost, in others pigment has returned to a marked degree to grey hair and the hair has become abundant. Local discharges from the ears, nose, etc., often greatly diminish or disappear without active local treatment. Urines loaded with urates become clear and may remain so as long as these remedies are kept up and even for years after they have been discontinued if a sufficiently prolonged course has been carried out.

Even when actual pyorrhœa alveolaris exists, I am of opinion a patient would do well to have a course of continuous counter-irritation before extraction is resorted to.

VACCINES.

I am aware that much has been done recently with suitable vaccines; my experience of this form of treatment is small, but my opinion so far is that the results may be at times very good. Nevertheless there is a good deal of uncertainty and a considerable amount of risk attending their use, especially in the hands of a novice.

Thyroid.

Continuous counter-irritation may be depended on to act very beneficially alone in a large proportion of cases, but I feel strongly that thyroid extract does much good as an adjunct. The dose must vary with the needs of each patient. One grain of the ordinary dry extract a day is sufficient for some. Patients taking it should be warned not to exert themselves for at least an hour after the dose; if only one a day is being taken it should be at bedtime. Massage is positively dangerous in acute cases; in any case it is best applied to muscles only, and very lightly at first.

Surgical procedures should be postponed until the disease process has been largely arrested. I have noticed adhesions, softening and intra-articular pads and fringes lessening purely as the result of improved function during treatment by continuous counter-irritation. It is now an established fact that the internal secretion of the thyroid has the power of softening adhesions, and pathological fibrous tissue of any kind, if it is abundant and of good quality. It follows as a matter of course that if the general health is improved as a whole, the thyroid gland becomes healthier and its secretion more abundant and of better quality.

At a meeting of the West London Medico-Chirurgical Society on April 12th, 1912, I expressed the view that patients suffering from arthritis deformans should not be encouraged to exert themselves, as is too often done, and that the breaking down of adhesions should be postponed until the patient had undergone a prolonged course of treatment with a view to arresting the progressive disease process. That no known treatment is invariably successful in accomplishing this, I am well aware.

Dr. Preston King, of Bath, agreed with me, and said that the breaking down of adhesions in the early stage of treatment had been abandoned in the Mineral Water Hospital as a barbarous practice.

Moreover, at any stage, great care must be exercised in doing this, and I emphatically state that few medical men are sufficiently expert to accomplish it really successfully without damage to the parts around the joints in some way or other. Bones have been broken, muscles torn, and acute inflammation set up in the joints by over zealous, improperly trained and inexperienced operators. It should also be strongly borne in mind that these patients are weak generally and as regards the nervous system in particular, therefore such manipulations may cause great shock. They should never be carried out except under full anæsthesia, and I find C.E. perhaps the most useful anæsthetic, say one of ether to two of chloroform. I speak from practical experience.

In addition to notes of my own cases I have included others kindly sent me by my friends Drs. S. Gurney Champion and A. Brook Batley. To them I tender my grateful thanks. The following have been selected as fairly typical.

I. *Greatly Improved.*—Female, æt. 32, married. Polyarticular, including jaws and cervical spine. Bedridden, helpless, very depressed mentally; unable to move hand or foot; skin harsh and scaly; greatly emaciated; feet and legs cold and "dead." Pyorrhœa alveolaris, purulent nasal catarrh, muco-purulent cervicitis uteri and vaginitis. Dyspepsia, insomnia, much constant pain. Duration over 3 years. Much previous treatment in hospital and out at Bath, Buxton, Bournemouth, &c. Said to be hopelessly incurable by several medical men. After four courses of spinal blistering patient became plump and active, able to do all her own housework. Subsequently medically examined at Buxton, Cambridge, and at a meeting of the Bournemouth Medical Society. Pronounced practically cured.

II. *Greatly Improved.*—Female, æt. 42, married. Rheumatoid, polyarticular, including temporo-maxillary. Bedridden, helpless, melancholic. P. 120. Temp., 100-101°; knee jerks plus, myotatic irritability. Pigmentation of skin; Raynaud symptoms; asthma. Greatly emaciated. Endo-cervicitis uteri. Duration over 3 years. Had tried all usual forms of treatment under experts in London and elsewhere. Blistered twice. February, '06—May, '06. Regained complete health and activity. Gained over 3 st. in weight. Asthma, melancholia and cervicitis cured. Iodised phenol applied to cervix uteri. Quite well when heard of four years later.

III *Much Improved.*—Female, æt. 58, single, cook. Polyarticular knees enormously enlarged; emaciated; loss of weight, 4 st. Always much pain, especially on movement. Calves, 12 ins. round. Duration over 4 years. All kinds of treatment previously. Spinal blister twice. Regained normal weight. Calves grew to 15 ins. round. Pain much less; sleep, appetite, and digestion restored. Had not retrogressed at end of 4 years.

IV. *Much Improved.*—Male, æt. 62, married, merchant. Polyarticular; very helpless; walked 200 yards with difficulty; barely able to write; unable to dress or undress without assistance Duration over 2 years. Spinal blistering once, also knees once. Result: Able to walk over a mile with comparative ease, write well, dress and undress unaided, and in much less pain.

V. *Distinctly Improved.*—Female, æt. 54, married Polyarticular; constant lumbar pain; at times quite helpless. Duration, 20 years. Impairment of sight and hearing. Spinal blistering once. Regained much muscular power, resumed laundry work; pain in back only occasional and much less. Sight and hearing much improved.

VI. *Distinctly Improved.*—Female, æt 60, widow. Polyarticular; knees osteo-arthritic. Emaciation; much loss of muscular power; very melancholic. Duration over 8 years. Spinal blistering twice. Emphatic in statements of improvement. Able to do housework with comparative ease. Much less depressed, much less pain.

VII. *No Improvement.*—Female æt. 55, window. Polyarticular; knees osteo-arthritic; much pain; mucous colitis; feeble digestive power. Spinal blistering twice. Patient denied herself necessaries, in fact, half starved herself to be able to give money to a dissolute son. Died.

VIII. *No Improvement.*—Male, æt. 62, married. Polyarticular including jaws. Quite helpless. Cerebral disease, not definitely diagnosed. Double optic atrophy, loss of sight outer half of both eyes. Spinal blistering twice. Died suddenly. No *post-mortem*. Probably cerebral hæmorrhage.

I have extensive notes of most of my cases and shall be glad to send further particulars to anyone interested.

THE PLACE OF BACTERIOLOGY AMONG THE SCIENCES. (a)

By JAMES RITCHIE B.Sc.Oxon., M.D., F.R.C.P.Ed.,

Professor of Bacteriology in the University of Edinburgh.

At the outset Prof. Ritchie referred to the benefactor to whom the University owed the foundation of the Chair of Bacteriology. Robert Irvine was born in 1839, he said, and early showed leanings towards chemistry, which he studied under Professor George Wilson. Devoting himself to the technical side of the subject, he was associated for the greater part of his life with one of the great Edinburgh firms. His contributions to technical subjects were considered of high value, and were on several occasions singled out for distinction by the learned societies to which they were communicated. His leisure was equally dominated by the spirit of inquiry, and his house was the centre of a scientific coterie. In Irvine there was a personality which appealed to his friends. Generous, courteous, kind, often self-depreciatory, but holding inflexibly to what he considered right, he was one of those rare souls whom none could decry. It was fitting that that day they should think with regard of one who wished the University well.

Beginnings of the Science.

The science of bacteriology, Professor Ritchie continued, had not yet attained its jubilee. Its beginnings were in the middle of the nineteenth century, when such questions as the nature of fermentation, the possibility of the occurrence of spontaneous generation, and the infectiveness of such diseases as tuberculosis were engaging attention. Its history was associated with three great figures—first, that of Pasteur, who showed conclusively that yeast was the cause of fermentation, and that putrefaction was due to bacterial action; secondly, Lister, who founded the antiseptic system on Pasteur's work on putrefaction, thus riveting the attention of the world on the part played by bacteria as originators of human suffering; and, thirdly, Koch, who in his work on anthrax furnished the first proof that the multiplication of a bacterium in the body originated a disease. From this date modern bacteriology started, for in his investigations Koch had substituted for the previous elaborate and imperfect *technique* simple and efficient methods for the isolation and growth of bacteria. The effect of Koch's work was that during the next ten years the connection of bacteria with most human infections, including tuberculosis, diphtheria, typhoid fever, cholera, and blood poisoning in all its forms, was established. While the contributions of bacteriology to medicine were the earliest, many other human interests had been benefited. Industries connected with food preservation had had their conditions revolutionised. Further, the enormous importance of the beneficent action of bacteria had emerged. Such primitive procedures as butter and cheese making had been placed on a new basis, and in agriculture it was now known that bacteria played an important part in the fertilisation of the soil. When he turned to consider the place to be assigned to bacteriology among the sciences, the dominant factor was that historically it came into prominence through the light it shed on infectious disease, and if it was borne in mind that nearly one-half of the deaths which occurred were due to infection, it would be realised that the disease-producing bacteria were the most important of all micro-organisms. Bacteriology was thus essentially a branch of pathology. The study of the pathology of infection had revealed the process to be a reaction in which the invaded body did not play a passive part, and this had led to important practical results, of which the introduction of the antitoxin treatment of diphtheria was an example. Bacteriology also came into close relationship with physiology, as the investigation of the properties of the body fluids in immunisation against infection had important relationships to what occurred in health.

(a) Abstract of the Introductory Lecture delivered at the opening of the Winter Session at the University of Edinburgh. Oct. 7th, 1913.

Results of Research.

Even the failures of bacteriology had had an effect on kindred sciences. Hitherto no bacterial organism had been proved to be the cause of such diseases as measles, smallpox, and hydrophobia, but the combined efforts of bacteriologists and proto-zoologists had been directed to the problems, and during the past few weeks the cultivation of a new type of parasite from hydrophobia and from infantile paralysis had been announced. As a branch of scientific therapeutics, bacteriology had diminished the death-rate in diphtheria, typhoid fever, and perhaps even in tuberculosis. Preventive sanitation had been given a rational basis, and the possibility of killing bacteria which had invaded the body, and which was the dream of many of the early workers, might any day become an accomplished fact. In a University curriculum bacteriology must be realised to be essentially a post-graduate study, to be engaged in by the man of parts who looked forward to occupying a foremost position in the practice of medicine, or as a specialist in sanitation, or in the public services—above all, by the man of originality whose ability made him capable of making original contributions to knowledge. The position of the subject in Edinburgh University was unique. It was known to be Mr. Irvine's prime desire to encourage original research, and this intention the University had loyally resolved to carry out, so that the function of the Chair was primarily to foster inquiry, and only secondarily to be an instrument of instruction. The carrying out of such a programme involved a heavy responsibility. For its success two conditions must be fulfilled. One was adequate financial provision. The old motto, "We cultivate learning on a little oatmeal," was for science now a dead letter. The Rockefeller Institute of New York, one of the great bacteriological laboratories, had an endowment of over a million and a half sterling. Was there a Scottish Mæcenas who was ready to give the University of Edinburgh the opportunity for which she was waiting? If there was, there would be little difficulty in fulfilling the other condition—namely, the provision of a band of talented workers who would be ready to take advantage of the opportunity and carry on the traditions which had already placed the Edinburgh School in the foremost rank.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

Resection-extirpation of Right Half of the Thyroid.—Mr. Berry operated on a girl, æt. 16, who had been admitted three days previously suffering from a swelling in the neck. For fifteen months she had experienced difficulty in breathing, which occurred even when she was sitting still. During the same period she had a swelling in the lower part of the front of the neck, which had increased in size during the last two or three months. This swelling had been painless. The throat had often felt rough and sore, and the patient had had difficulty in swallowing solid food, and in a lesser degree in swallowing fluids. About a year ago the girl had been given iodine to paint on the swelling.

On examination, there was a uniform enlargement of the whole thyroid gland. The enlargement was not very great in any part, and was painless, uniform and fairly soft. No pulsation of the gland could be felt, and the whole swelling moved on swallowing. It extended backwards under the sterno-mastoids on both sides, downwards to the clavicle, and upwards to the upper border of the thyroid cartilage. By examination of the throat the tonsils were seen to be enlarged. The patient did not seem nervous; there was no exophthalmos and no tremor. The pulse was rather rapid, heart, lungs and temperature normal.

Mr. Berry said that the operation was undertaken for parenchymatous goïtre on account of the difficulty of breathing. He pointed out that in these young cases the trachea was somewhat softer than usual and more easily compressed, especially when the goïtre lies low down. Open ether anæsthesia was slowly and carefully brought about, and at no stage of the operation was the patient at all deeply under. Mr. Berry pointed out that if the dyspnœa is very severe no anæsthetic at all is given; he has practically given up chloroform for these operations.

The usual collar incision was made, care being taken to keep it in the line where a necklace would be worn so that the scar could be hidden if necessary in future life. The incision extended through the skin and platysma, both of which were turned up together in a flap reaching as high as the hyoid bone, care being taken not to wound any of the anterior jugular veins. All bleeding points were immediately secured with pressure forceps; the last were left on. The infra-hyoid muscles were separated from one another, and were then cut across between clamps high up on the affected side near the hyoid bone. The gland being thus thoroughly exposed, the muscles having been pulled back, it was drawn forward by a curved director placed under the superior thyroid vessels, these last being clamped and doubly ligatured; many small vessels on both sides were also secured and clamped, as also the main inferior and middle thyroid veins on the outer side. The lobe was then rolled outwards and the pedicle cut through from the inner side, branches of the inferior thyroid artery being secured by forceps which were left on, and the gland removed. The vessels on which clamps had been left were now secured one by one with very fine silk ligatures. The patient, who at this stage was very lightly under the anæsthetic, was induced by tickling the pharynx to strain in order to test the efficacy of the hæmotasis.

Mr. Berry pointed out the necessity of securing every vessel, even to the smallest vein, lest recurrent venous hæmorrhage should take place. The total amount of blood lost during the whole operation was well under half an ounce. The infra-hyoid muscles were sewn up, and a glass drainage tube left in, the the skin and platysma being joined with catgut.

Mr. Berry said the treatment after operation would be a pint of saline by the rectum immediately; the patient would be placed in a sitting position in bed after two or three hours, and she would be allowed to get up on the following afternoon. The drainage-tube would be removed the following morning.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

Clinical Section.

Meeting held Friday, October 10th, 1913.

The President, Mr. Charters J. Symonds, in the Chair.

EXHIBITION OF CLINICAL CASES.

Dr. J. D. Rolleston exhibited a case showing the value of salvarsan in the local treatment of Vincent's angina. It was that of a man, æt.20, who was admitted to hospital on August 2nd, 1913, certified to be suffering from diphtheria, on the seventh day of the disease. The fauces were slightly injected. From a dirty deposit on the right tonsil numerous Vincent's organisms were obtained. Throat cultures taken on admission and on each of the two following days showed absence of diphtheria bacilli. No antitoxin was given.

On August 3rd, a well-marked ulceration of the right tonsil was present. In spite of various local measures successively adopted—viz., application of methylene blue powder, syringing with a solution of potassium chlorate and lavender, and painting with tincture of iodine, the ulceration spread on to the palate and uvula, which became œdematous and covered with a dirty slough. There was considerable sub-maxillary adenitis. The throat became increasingly painful, and there was some difficulty in swallowing and pain in both ears.

On August 17th all other treatment was omitted and a throat swab moistened with glycerine was dipped in salvarsan powder and rubbed all over the affected area. The application was not painful, and within four hours the throat felt much easier. Subsequently three more applications of salvarsan were made. The slough entirely cleared off and the adenitis subsided. Vincent's organisms disappeared from the smear. On his discharge on August 30th only a very small opaque area was visible on the uvula, and within a week the throat became perfectly normal and has remained so since. Although the local discomfort was considerable, there was no constitutional disturbance, the urine was free from albumin, and the temperature was normal throughout his stay in hospital, except on the day of admission, when it was 99° F. There was no history or evidence of syphilis, and Wassermann's reaction (August 17th) was negative.

Mr. G. H. Makins showed a case of actinomycosis of the cheek treated by parenchymatous injections of formalin. The patient, a boy, æt. 17, was admitted into St. Thomas's Hospital in January, 1913. Two months previously an alveolar abscess had developed in connection with some carious teeth. The abscess was incised, and shortly afterwards a hard, brawny swelling developed in the right cheek. On admission, this swelling occupied an area of about the size of a half-crown piece. It was bluish-red in colour, very hard, and firmly fixed to the surface of the maxilla. Four discharging sinuses were present, and on examination of the pus exuding from these the streptothrix of actinomycosis was discovered.

During the month of February iodide of potassium, beginning with 5-gr. doses, rapidly increased to 20 gr., were administered internally three times daily. On February 21st two hypodermic syringefuls of 4 per cent. formalin solution were injected around the periphery of the indurated area and into the margins of the area itself. The injection was followed by considerable swelling of the cheek and lower eyelid. A second injection was made on April 4th, after which all the sinuses closed. Meanwhile considerable diminution occurred in the extent of the induration.

Further injections were made on April 22nd, May 30th, and July 16th. Each injection was followed by considerable local œdema which rapidly subsided, after which the indurated tissue became less in extent and freely movable upon the maxilla. The injections were necessarily made around the circumference, since the fluid could not be freely forced into the indurated area.

When exhibited the cheek was nearly normal, the only fixed spot corresponding with the cicatrix of the largest of the sinuses present when the formalin treatment was commenced.

Mr. T. H. Kellock showed a case of complete destruction of a part of the diaphysis of the tibia by acute osteomyelitis. The boy, æt. 8, two years ago had a sudden acute illness associated with much pain and swelling of the left leg below the knee. An operation was performed and some bone removed. Several months later a second operation was performed. The wounds had quite healed. There was considerable mobility between the upper and lower ends of the tibia.

A skiagram showed that the epiphyses were present and there was some attenuated bone leading from them, but for a considerable space there was complete absence of bone in the situation which the shaft of the tibia should occupy. The fibula appeared to be unaffected.

Mr. Kellock also showed a case of osteogenesis imperfecta with multiple fractures. The patient was an orphan boy, æt. $11\frac{1}{2}$. He was breast-fed for nearly three months. It could not be ascertained whether any deformity was present when he was an infant. He did not walk until he was four years of age, and was said not to have talked until six months ago. There were five brothers and sisters, all of whom were said to be healthy.

The child presented marked deformities of the long bones; the tibiæ and fibulæ were markedly bowed forwards; the femora were curved; the humeri showed marked thickening about the bicipital groove. Some of the epiphyses, especially those at the wrists, were enlarged.

Skiagrams showed the long bones to be more translucent than normal, and to show comparatively little compact tissue. Spontaneous fractures were seen in the tibiæ, radii, and ulnæ, with practically no displacement of the fragments. Wassermann reaction was negative.

Dr. W. Essex Wynter showed two cases of splenic enlargement, hæmorrhage, anæmia, with oral sepsis. (1) A man, æt. 50, had severe epistaxis in May, 1913. He went to hospital, and the teeth were attended to after the bleeding had been stopped. On August 10th there was sudden pain below the left ribs; the spleen was found enlarged, and when admitted to hospital on August 20th it extended to within $1\frac{1}{2}$ inches of Poupart's ligament, and 2 inches beyond the umbilicus in the middle line. It was firm and not then tender. The heart and lungs were normal.

On September 10th sudden and severe pain occurred over the spleen, with subnormal temperature, vomiting and collapse. Friction could be heard over the organ, which was apparently the seat of an infarct. A similar case occurred two days later, but less severe, and no friction could be detected. On September 18th severe and persistent epistaxis occurred, which was only arrested by plugging the nostril. On September 25th this recurred with less severity, both attacks being preceded by severe headache. No lesion of the mucous membrane could be detected. A blood-count showed a gradual decrease in the number of red and white cells (from 25,000), an increasing proportion of lymphocytes, and a raised colour index. The urine contained 0.3 albumin per cent., but was otherwise normal. The teeth were much decayed, had been entirely neglected, and there was extensive pyorrhœa.

In Case 2 arteritis obliterans also occurred. It was that of a woman, æt. 55, who had suffered for twelve months with attacks of pain in the toes and fingers, and a month ago submitted to amputation of the left second toe for moist gangrene; about the same time the third toe on the same foot was affected with dry gangrene. Ten months ago there was slight uterine hæmorrhage. The patient continued at work as housekeeper, though feeling weak and tired. On August 20th to August 22nd last, severe hæmorrhage from the nose and mouth occurred, the loss of blood being estimated at two pints. Previous health had been good.

On admission to hospital on August 25th, the skin exhibited a waxy pallor. The spleen, which was hard and not tender, could be felt two inches below the costal margin, and there was slight enlargement of the liver with similar characters. The abdomen was lax and no free fluid existed in the cavity. A hæmic murmur could be heard over the præcordia, otherwise the heart and lungs showed no physical signs. Partial dentures were worn over numerous stumps and the gums were in a very septic condition. Wassermann's reaction was negative. The blood-count showed anæmia, with a leucocytosis of 38,400 and a lowering of the colour index.

Sir **Frederic Eve** showed a case of angioma of the synovial membrane of the elbow. Girl, æt. 11. One year and nine months ago the elbow became swollen and painful, and she was laid up with it for a fortnight. The swelling was attributed to a blow on the part two or three years previously. Since then the elbow had become swollen every few weeks.

When exhibited there was a bluish bilobed swelling on the outer side of the head of the radius; the swelling disappeared on raising the arm; after applying an elastic ligature to the upper arm it stood out prominently and the circumference of the limb at the site of the swelling increased by ¼ in.

The exhibitor said that he had drawn attention to this condition in a paper in the *Clinical Society's Transactions*, 1903, xxxvi, p. 204, and described two cases of angioma involving only the synovial membrane, and two others implicating also the surrounding muscles. The chief interest of the condition lay in the diagnosis from localised tuberculosis of the synovial membrane. This might usually be made by observing the changes in the swelling induced by alterations of the venous circulation. Angiomata of synovial membrane often gave rise to a good deal of pain, increased by exercise. There might be tenderness, limitation of movement, wasting of muscle, and two of the writer's cases complained of starting of the limb at night.

Sir **Frederick Eve** also showed a case of Bazin's disease. The patient was a woman, aged 31. The trouble began as a hard swelling on the outer side of the left leg which broke down and discharged. An abscess formed, which gradually spread. When Sir Frederick Eve first saw her in March, 1913, there were two thin oval cicatrices on the outer side of the lower third of the left leg. At the lower end and outer margin of these cicatrices was a rim composed of irregular pit-like ulcerations covered with flabby granulations. The general appearances were those of a serpiginous ulcer. There was also a very small ulcer on the inner side of the same leg.

The patient appeared perfectly healthy, and a Wassermann reaction was negative. The ulcerated areas were excised and skin-grafts were applied. At the same time the affected part was exposed to the X-rays. As a result of this treatment complete healing took place. Later a few pit-like ulcers reappeared, but they healed after applications of pure carbolic acid and fomentations of 1 in 5,000 watery solution of biniodide of mercury, and she returned home. About three weeks subsequently the small ulcer on the inner side of the left leg broke down again, and a sore appeared on the right leg. Small areas of the margins of the scars on the outer side of the left leg also broke down.

While in hospital she had been treated by X-rays and had been kept in bed.

Mr. **Percival P. Cole** showed a case of tumour of the thigh in a man, æt. 45, who had fractured his right femur on February 10, 1913, at the junction of the middle and lower third. Considerable shortening and deformity followed, but owing to the patient's cardiac condition it was deemed inadvisable to plate. He was treated on a Hodgen's splint for a few days, but pressure sores began to develop, and extension apparatus had to be abandoned. He was discharged eleven weeks after admission. An excessive amount of callus had been thrown out and union was not complete.

He was re-admitted on September 25th. The swelling of the right thigh had gradually and painlessly increased, showing a circumference of 22½ in., as against the normal 14¾ in. The swelling was elastic and semi-fluctuating, feeling like a tense cyst. Exploratory incision was made under spinal anæsthesia, when some mucoid gelatinous fluid escaped. The tumour was composed of soft, jelly-like material, with spicules of bone embedded therein. This bled freely and surrounded the bone ends, which could just be felt. On microscopic examination it was found to be a myxo-chondroma.

Dr. **Arthur F. Hertz** and Dr. **W. Johnson** showed a case of bilateral atrophy of the face. The patient was an Italian, æt. 38, who presented himself for weakness of the right side of his face, complaining that the right eye closed incompletely during sleep. His face showed a well-marked condition of atrophy on both sides, especially the left. The cheeks were extremely hollow, and the tissues covering the bones of the face were very wasted. He showed well marked signs of chronic lead poisoning with great weakness of all the extensor muscles of the wrists and fingers of both sides. He had a blue line on his gums and was very constipated; he had had numerous attacks of abdominal colic. He showed no other signs of disease of his nervous system; the reflexes were all normal.

Mr. **H. Gardiner** showed a case of neuropathic arthritis of the wrist in a man æt. 42. The right thumb was wounded by a splinter nine weeks ago. A good deal of pain and swelling occurred, the swelling reaching half up the arm. This quickly subsided, but left the wrist-joint swollen but painless.

The right wrist was swollen and contained fluid. There was a dorsal dislocation of the wrist-joint, easily reduced. The joint was quite disorganised with osteophytic changes and rough grating. It was entirely painless and the muscular sense was diminished. Sensation of heat and cold was also absent. Tactile sensation was affected to a slight degree. There was some scoliosis that had been present for many years.

Mr. **Gardiner** also showed a case of bilateral cervical ribs in a girl æt. 17. She complained of slight weakness of both hands, noticeable chiefly when stretching big chords on the piano. The weakness had been noticed for three to four years. On examination very little abnormal could be detected in either hand, but the thenar and hypothenar eminences were not so well marked as one would have expected. X-ray examination of the neck showed the presence of bilateral cervical ribs, very well developed.

Dr. **H. D. Rolleston** and Mr. **E. F. W. Grellier** showed a case of unilateral clubbing of the fingers due to an axillary aneurysm. It occurred in a man, æt. 63, whose serum gave a positive Wassermann reaction. No difference in blood pressure or pulse tracing could be demonstrated between the two radial arteries.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

Opening Meeting held October 3rd, 1913.

Abstract of the Presidential Address by Mr. A. Ernest Maylard, M.B., B.S.Lond.,

ON DILATATION OF THE STOMACH.

Dealing first briefly with the normal stomach, Mr. Maylard referred to the development of the organ, which went on rapidly during the first year of life and then more slowly till full growth was reached in the third decade. Abnormal growth might result in an unusually large stomach, or diminished growth in an unusually small one, apart from any pathological condition. As to the shape of the normal stomach, modern surgery and X-ray photography had shown that the stomach was not a sort of permanently dilated viscus of fixed shape, but an organ of very varied dimensions, and sometimes extremely limited in its location, presenting much more the appearance of a tube than a bag, and, when peristalsis was taking place, resembling much more a portion of the intestinal canal than an organ possessed of any peculiar and specially complicated action.

Dealing, secondly, with pathological conditions, it was doubtful if there was any such condition as uncomplicated dilatation or idiopathic enlargement of the stomach. It was possible that one enormous meal or the more or less constant ingestion of large quantities of food or fluid, might so over-distend the viscus that its parietes became temporarily paralysed, just as the urinary bladder might become paralysed and dilated by prolonged retention of a large quantity of urine. But it was doubtful if a simple chronic gastric catarrh could lead to dilatation. When dilatation was present it was much more probable that the catarrh was a consequence and not a cause; and that there was some obstruction which had indirectly given rise to the inflamed condition of the mucous membrane. The only exceptions were cases in which adhesions had interfered with efficient contraction and completely emptying the organ. Nephroptosis sometimes acted as a mechanical cause of dilatation, either by kinking a portion of the duodenum or by pressing on the bowel. Further, non-obstructive dilatation was a condition unknown in any other part of the alimentary canal, or, indeed, in any viscus which possessed muscle parietes.

Diagnosis in the early stages of the disease was difficult because so many cases temporarily improved under certain forms of treatment. The first result of any obstruction was increased contraction, followed by increased muscle development; but if the obstruction continued a time came when the hypertrophied muscle parietes failed to overcome it and gave way to relaxation. Dilatation then commenced and the viscus remained enlarged until the muscle recovered from its exhaustion and was again fit to overcome the obstruction. Hence arose many clinical difficulties. Thus, if a patient in the early stages of his trouble were fed with easily digestible food the stomach could overcome the obstruction and there might be no symptoms even of gastric disturbance; but if he returned to ordinary diet, symptoms reappeared. Or such a patient might complain that when feeling overtired or run down in health his gastric symptoms became augmented, and that as his general condition improved, by rest or holiday, they disappeared, only to return when he resumed his ordinary work and mode of living. In nearly all cases there followed sooner or later retention of the ingesta with fermentative changes. If by lavage these were prevented, the motor functions of the viscus might be so improved that normal contractions would occur and symptoms of dilatation disappear, to return when lavage was desisted from. Similar temporary improvement could be secured by massage or electrical treatment.

It was in the pyloric antrum that dilatation first showed itself. This part, becoming enlarged, was carried downward and outwards to the right of the middle line, and sometimes showed distinct hernial pouching. At a later stage dilatation involved the whole body of the viscus, which, as in a striking case operated on by Mr. Maylard, might become converted into an enormous tense thin-walled cyst, resembling an ovarian cyst.

The Causes of obstruction might be connected with the duodenum, the pylorus, or the body of the stomach, and might be innocent or malignant. Obstruction might be caused by kinking of the canal, the result of simple ptosis or from dragging down by adhesions; or by narrowing of the pyloric aperture due to congenital hypertrophy or to some check in the normal process of development. The latter class of case occurred mostly among young adults, who, while healthy in every other respect, suffered from periods of indigestion, and showed evidences of intermittent attacks of gastric dilatation. Spasmodic contraction of the pylorus, said to be associated with hyperacidity, was a possible but improbable cause of obstruction. In the diagnosis of dilatation percussion alone or in conjunction with auscultation was not of much service except in advanced cases, as a perfectly normal viscus might reach down to or beyond the umbilicus, and splashing might be found under quite normal conditions up to four hours after a meal. Two of the most striking symptoms of dilatation were the vomiting or withdrawal of large quantities of brownish sour-smelling material like thin porridge, and the effects produced by mechanical distension such as the pumping in of air by a Higginson's syringe. X-ray photography had recently added considerably to the means of diagnosis. Skiagrams taken after the ingestion of bismuth meals gave very clear and instructive information in cases of marked obstruction. When obstruction had not led to very pronounced dilatation, the pyloric half of the organ assumed a transverse position, and presented the appearance described by Cole as "prognathian or undershot." In advanced cases the meal was seen to lie in the lower part of the viscus, due to the fact that the parietes of the stomach had lost all power to contract on the contents, so that they simply gravitated to the most dependent part of the organ.

As to *prognosis*, it was almost right to say that once obstruction always obstruction, as the improvement which often followed careful dieting and lavage was as a rule only temporary. Often, prior to dilatation, the stomach parietes, making an effort to drive out the contents, underwent spasmodic contraction which caused great pain. In cases where dilatation had become permanent, gastric tetany was an occasional and very fatal result, due probably to some toxine produced among the fermentative products of the retained ingesta. Where carcinoma was the obstructing cause, death might result from one of the many complications incident to that disease. An interesting case of the natural cure of obstruction was reported by Dr. Bradshaw in the *Lancet*, but such an event must be extremely rare.

As to *treatment*, recognition of the fact that the great majority of cases of dilatation of the stomach were due to mechanical obstruction would save many a patient months, and even years, of ineffectual dietetic and medicinal treatment, by the timely intervention of surgery. It was a mistake to attempt to treat the dilatation, which was only a symptom, regardless of the cause upon which it depended; hence lessening the size of a big stomach by puckering or infolding (gastrorraphy) was seldom done now. Whatever operation was undertaken must aim at overcoming the obstruction. At present, gastrojejunostomy was the method most in vogue, but cases had to be dealt with according to the nature of the obstruction. Thus, if the cause were adhesions, their separation (gastrolysis) might suffice; if it were nephroptosis, fixation of the kidney would be necessary. In carcinoma of the pylorus, if extirpation of the disease seemed feasible, a sub-total gastrectomy had to be added to the gastro-jejunostomy. In the condition described above of narrowness of the pyloric orifice, the result of defective development, Finney's modification of gastro-duodenostomy was to be preferred, as it permitted the enlargement of the narrowed outlet without in any material way disturbing the normal function of the duodenum. Loretta's operation of forcibly stretching the constricted canal (pyloro-diosis), and the Heineke-Mikulioz operation of pyloroplasty were rarely practised nowadays. How successful were the various methods employed for the treatment of dilatation was best testified by the excellence of both the immediate and remote results. For, in the former, the mortality after operation, in experienced hands, did not exceed 2 or 3 per cent.; while in the latter there could be no one present who had not seen a life of perpetual gastric misery changed into one of permanent gastric joy.

On the conclusion of the address, Dr. James R.

Riddell gave a lantern demonstration of skiagrams illustrating various appearances of the stomach in conditions of health and disease.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Oct. 11th, 1913.

Poisoning from Mushrooms.

Every year records numerous cases of poisoning from mushrooms, many of which are fatal. As this is the season of these cryptogams, a few words on the cause, symptoms and treatment of fungoid intoxication may be of service. It is true that such cases are rather rare in England, where but one or two varieties of mushrooms are considered edible, but they are very frequent in France, where several varieties enter into the food of the people, the difference between the toxic and non-toxic fungi being so slight to the inexperienced that accidents are frequent and apparently unavoidable.

Toxic mushrooms are divided, says Dr. Chauvet, into two classes—dangerous and mortal. The first class pertains to the Amanites (Amanita pantheria), Amanite fly-killer (Amanita muscaria). These mushrooms contain a poison called "muscarine."

The *début* is brusque—from one to three hours after ingestion of the fungi. The patient complains of violent burning in the epigastrium, is seized with vomiting and profuse serous diarrhœa. The temperature is normal, the pulse regular, the urine scanty. After an hour or two, the patient becomes delirious, cries out, gesticulates, laughs immoderately, tries to walk, but staggers like a drunken man. At the end of some hours the delirium ceases, the gastro-intestinal troubles amend, the patient falls into a slumber, and finally awakens feeling much better but confused as to what passed.

Such is the usual evolution of poisoning by muscarine. A fatal termination arrives only where a very large quantity of the cryptogams has been ingested, or where the patient, by reason of his age or a pre-existing lesion (cardiac, hepatic, renal) is in a condition of inferiority as regards the toxic element.

Muscarine poisoning is consequently grave but rarely mortal. Its relative benignity is due to the fact that the toxic substance is rejected by the initial accidents—vomiting and diarrhœa.

Treatment.—Encourage vomiting by tickling the back of the throat with a feather or by giving warm water to drink; no other emetics. The stomach pump should be used when possible, and the patient given a purgative dose of castor oil. Efforts should be made to increase the quantity of urine by diuretic drinks and especially by subcutaneous injections of artificial serum (one quart daily). These injections relieve the thirst, dilute the toxines, provoke diuresis, and procure an agreeable sensation of *bien être*. Certain remedies have been recommended as antidotes—atropine, charcoal powder, tincture of iodine—but their efficacy is doubtful.

The second class of toxic mushrooms comprises the different varieties of phalloid amanites (Amanita phalloides). These fungi owe their toxicity to a mortal hæmolytic poison—phalline. Here the period of incubation may last ten, twelve, or even twenty-four hours. The patient is seized with vertigo and a sensation of strangulation, he complains of great burning in the stomach, intense thirst, and violent cramps in the arms and legs. Incessant vomiting sets in with excruciating pain in the epigastrium followed by profuse and fœtid diarrhœa; oliguria is almost absolute. It is at this stage that medical assistance is called for. The patient is found in bed, the features drawn, the pupils contracted, the extremities cold, the pulse small and hypothermia. Frequently at the end of a few hours matters seem to mend; pain, vomiting and diarrhœa are relieved, the patient falls into a sleep, and hopes are entertained. But soon all the alarming symptoms return with increased violence: the cramps set in once more, the extremities are covered with a cold sweat, the face becomes livid, the pulse weaker and weaker, dyspnœa distressing, and the patient succumbs the same day or the following in full possession of his faculties. Recovery is exceptional.

Treatment.—In addition to that mentioned in the case of muscarine poisoning, the heart must be sustained by injections of ether, camphorated oil, sparteine, etc.; no alcohol should be given, as it facilitates the absorption of the poison. Hypothermia should be treated by dry friction of the skin and hot-water bottles; morphia, although irrational, will have to be given to relieve the intense suffering, the dyspnœa by injections of ether and inhalations of oxygen gas.

Statistics.

The total number of doctors of medicine in France is 20,809; that of dentists 2,848; midwives, 13,066; chemists, 11,585. The proportion of doctors to the population is 1 to 2,000. Of the Departments, the Seine (Paris) contains, as may be naturally supposed, the largest number (4,393), while the Hautes Alpes has the smallest (29).

GERMANY.

Berlin, Oct. 11th, 1913.

At the Schlesische Gesellschaft für Vaterländische Kultur, Hr. L. Fraenkel showed a case in which

Delivery had Taken Place after Operative Union of a Double Uterus.

As the patient was about to return to her home he wished to show her to the Society. She first came under the speaker's care two and a quarter months ago, seeking advice because her children could not be born alive. This failure had occurred three times. The husband was a healthy man, and the only thing about her that was wrong was that the genital organs were double in such a way that the two horns of the uterus were completely apart, whilst below was a single collum that was divided into two halves by a central septum wall. Besides all this there was a vaginal septum. It was not difficult to understand that a child could not be brought to maturity in a half-developed uterus. He therefore proposed to the patient as the only rational method of procedure to unite the two halves of the uterus by an operation, but at the same time he would not raise her expectations to too high a pitch by promising that the operation would enable her to give birth to a living child. Such an operation had been proposed, and even carried out by Strassmann, but without attaining the end desired—that of rendering possible the birth of a living child. The speaker excised the bands of the vagina and of the collum per vaginam, after which laparotomy was performed. A large wedge-shaped piece was then removed from the opposite surfaces of the two cornua, and the opposing parts were brought together. To permit this, the bladder had to be separated, and the lower part of the wedge incision to be carried deeply into the collum of the uterus. The hæmorrhage during the operation was arrested in the same way as during the operation for Cæsarean section, by compressing as well as possible the upper angles of both sides of the double uterus. The extent of suture line was very great, but in the end an organ was produced that looked not much unlike a rather large simple uterus. The course of recovery was quite smooth. The patient went home, and for two years nothing more was heard of her, until a second case of the kind presented, when the first was brought into remembrance. Inquiry was now made, and an answer came to the effect that the patient was quite well, that she was pregnant again, and that she had already passed the period at which her former miscarriages had taken place. As the patient lived in a remote country district of Poland, as the lines of cicatrix were so extensive, and as there seemed to be a great danger of something giving way, he begged her to come into the hospital for the confinement. She came, and nine days ago the patient was safely delivered of a 6-lb. child spontaneously and quite easily. The placenta also separated and came away without the least trouble. Recovery was uninterrupted, and the patient had left the hospital. After such an experience, the speaker would operate in another similar case with great confidence. Such a case was not far to seek, as only a short time ago a patient with a double uterus was delivered of twins—one in each perfectly separate and distinct horn of the uterus, as a matter of fact. One was a transverse presentation with a prolapse of the cord before the commencement of labour, the other (the first-born) had placenta prævia. Both were unviable. In this case also it was the third time she had failed to carry the offspring to maturity. After the happy result of the former case the speaker held himself justified in proposing to operate as in the first case. (It was later announced that the operation proposed had been carried out, but the result had not been made public.)

In the treatment of

Disturbances of the Internal Secretions of the Ovaries

Dr. Hirsch, of the Israelitischer Krankenheim, with ovarian extract, has met with a considerable amount of success. The preparation he makes use of is a liquid one, 2.2 c.cm. of which correspond to 2 grm. of ovarian tissue. He used it in 28 cases of climacteric troubles, 37 cases of dysmenorrhœa, 16 of oligo- or a-menorrhœa, 3 of pruritus vulvæ, and 2 of skin affections associated with pregnancy. The climacteric disturbances, whether following natural cessation of the menses or the result of castration operations, were favourably influenced by injections of glanduovin, as he names the preparation (successful in 25 out of the 28 cases in which it was employed). Of dysmenorrhœic troubles, in 37 cases failure was noted in only five of them. In the cases of so-called Mittelschmerz the treatment was without avail. In 16 cases of oligo- or a-menorrhœa there was only one failure. In two dermatoses of pregnancy only one was influenced favourably. In two cases of pruritus vulvæ of pregnancy only one was influenced favourably, and the like in two non-pregnant cases. It was made use of in 19 cases of hyperemesis gravidarum, but success was met with in only nine of them. The injections were given daily until a result was obtained. Generally two or three injections sufficed. As to the manner of action, the writer is of opinion that the favourable results, when present, are due to hormones that are introduced strengthening the action of the natural ones.

AUSTRIA.

Vienna, Oct. 11th, 1913.

Ferments Destructive to Special Organs, Found in Blood of Mongolians.

At the recent meeting of the Congress in Vienna, Dr. P. Jodicke discussed the interesting subject of the special ferments found in the blood of mongolians which have a specifically destructive effect on certain organs. He pointed out at the opening that certain forms of mental weakness have received special attention during the past few decades from the distinctive type of physiognomy which seems to mark off the affected individuals by groups characterised by recognisable features. Cretinism and myxœdema had their turns of special attention; and still more recently the subject of mongolism has been critically examined by observers in many nations. Numerous papers and monographs have discussed the characteristic bodily features of mongolism, and the similarity of these to the corresponding peculiarities of the physiognomy of the Mongolian race—the cranial outlines, form of the brain, the eyes, heart, mouth, tongue, hands and fingers, as well as intellectual capabilities. Still it must be admitted that our knowledge of, and views regarding, the intimate nature of mongolism still remain largely hypothetical. Many casuistic contributions have displayed collation of much clinical material without advancing a single new enlightening viewpoint. Since the first discussion of mongolian idiocy by Langdon Down in 1866, the more prominent contributors have been T. Smith, Sutherland and Garrod in England; Bourneville in France; Kassowitz in Austria; Vogt, Weygandt, Scholz and Siegert in Germany—all of whom have contributed liberally to the question of differentiation of myxidiocy. Siegert regards this clinical condition as one of exhaustion: in case of its older subjects resulting from prolonged and successive periods of illness; in the young, from tuberculosis, lues, neuropathic conditions, etc., of degenerate parents—these are more likely to occur in the more prosperous classes. According to the results of Weygandt's researches, degenerative processes have interfered with the development of the cerebral cortex. Other authors accuse defective development of the cerebral convolutions, flattening and falling in of certain portions of the cortex, defective development of the pons varolii, absence of the corpus callosum, etc.—defects which have, however, been noticed in other forms of idiocy.

Close relationship was soon observed between the symptomatic conditions of myxœdema and mongolism, and structural alterations in the thyroid gland. Philippe and Oberthner placed first sclerotic changes and proliferation of connective tissue in the thyroid gland. In the case of an affected child, who died of diphtheria, Fromm and Lange found proliferation of the interstitial connective tissue with extensive colloid degeneration. Kassowitz concluded that there was an essential association with myxœdema. It cannot, however, be accounted for by mere failure of the thyroid functions, as the same cause could not produce results so various. There must be, probably, a lesion of some other organ as well, one of which the effects tell on the thyroid gland also with deleterious effect. This view is adopted by Sanctis and Buschan. Schüller and Alt, having regard to the clinical conditions which characterise derangement of the ductless glands, look upon mongolism as a case of primary dysgenitalism, comparable to the infantile and acromegalic giant growth and adiposity. Siegert met with a case associated with persistence of the thymus gland, which showed excessive hyperplasia.

Thus we see that the varied co-existing conditions fail to throw light on the genesis of mongolism. But the dialytic experiments of Aberhalden seem to promise better. When defective development of the brain—in varied manifestations—gives rise to clinical features so characteristic as to make all the victims referrible at sight to a single family group, it is unfortunate that we cannot trace the serial linkage in the chain of causes. An interesting item of information is here presented by the fact that in some typical cases of mongolism, as in cases of athyroidism, there has been found an abnormally high capacity for assimilation of grape-sugar. And Dr. Jodicke, while agreeing from his own experience with the recorded concidence of defective thyroid function with mongolism, would not regard the cause-and-effect relationship as definitely established. With a view to settlement of this obscure question, he proceeded to separate the internal secretion by the dialytic process devised by Aberhalden. The details of his experimental procedures were too minute and complicated to be summarised here, but the net result was, unhappily, negative. In no one of the seven cases of pronounced mongolism which he investigated was he able to demonstrate the existence of functional incapacity of the thyroid gland. But he hopes that by persisting in this line of research he will be able to attain positive results in the near future.

EDINBURGH.

Clinical Instruction in Edinburgh.

Although at the time of writing we still await the appointment of the new Professor of Clinical Medicine, the re-arrangement of the teaching of clinical medicine, following on the agreement made between the managers of the infirmary and the University authorities, which was referred to some months ago in this column, becomes effective from the beginning of this session.

Sir Thomas Fraser, who has returned to work after the tedious convalescence imposed on him by his accident last November, devoted the inaugural lecture on clinical medicine to a description of the new system. He described it as epoch-making, one of its salient features being an incorporation of the whole medical staff of the Infirmary in the University, and the abolition, in all essential points, of the distinctions between professors and extra-mural lecturers. The ordinary physicians become senior lecturers, the assistant physicians lecturers, and the tutors University assistants. So long as there exists a University group of wards and an extra-mural group of wards the tendency was inevitably for the respective students to gravitate in different directions, and this had limited the full use of the wards and the teaching power of the staff. The new system includes the employment of all the senior lecturers as examiners in clinical medicine, and an allocation of the students among the different teachers, so that no clinic may be unduly crowded. The assistant physicians, whose duties have hitherto been in large measure restricted to the out-patient department, will in future take part in the teaching in the wards; they thus assume the position of *chefs de clinique,* who have existed with so much advantage for many years in France and Germany. Instruction in special clinical work, especially in its more purely scientific aspects, is consigned to the clinical tutors, and for this purpose five rooms have been fitted up with suitable apparatus. In commenting generally on the new system, Sir Thomas Fraser said that it would be a fatal error for a student to wander from one clinic to another, and that he must attach himself for at least six months to the teacher of his choice. The main features of the agreement, apart from those referred to by Sir Thomas Fraser, may be summarised as follows:—The wards at present under the charge of the Professors of Materia Medica and Pathology are definitely pledged to the University. Appointments to professorships of clinical medicine are to be made in consultation with the manager of the Infirmary. Appointments to the medical staff are to be made on the recommendation of a selection committee, representing the Managers, the University, and the Royal Colleges. The assistant physicians and the clinical tutors are to be paid by the University, while the physicians (senior lecturers) are to receive the class fees, less certain deductions, and an honorarium for examining. In surgery the arrangements are, *mutatis mutandis*, much the same. Clinical gynæcology is to be dissociated from clinical medicine and made a special department, the two gynæcologists becoming senior lecturers, and the two assistant gynæcologists becoming lecturers with salaries. In the pathological department, Professor Lorrain Smith becomes Consulting Pathologist, and Dr. Shennan, the present Pathologist, becomes Lecturer on Morbid Anatomy, with a salary. When Dr. Shennan ceases to hold office as Pathologist, he will be succeeded by Professor Lorrain Smith. The whole plan in effect draws clinical teaching and pathology into the University, and breaks down the traditional wall between the extra-mural and intra-mural school. That the time for the change has come is evident to all, and many of those who were strongest in their support of the extra-mural school in the past now see that with changing circumstances the best way to maintain it in vigour as a part of the medical school is to seek the friendly aid of the University. Both bodies are strengthened by union.

GLASGOW.

OPENING OF THE WINTER SESSION.

WITH the opening of the winter session of the University and the extra-mural schools, following on the opening last week of the other medical schools in Scotland, the medical year has now fairly begun. The medical faculty of Glasgow University has never, on the whole, been stronger or better equipped than it is at present. Much of the present position of this faculty is due, of course, to the money which the University generally has been receiving, in common with other universities, from the public purse, and to the lavish benefactions which, especially of late years, the medical faculty has received from private donors. The stimulus of competition with the extra-mural schools is, no doubt, also beneficial.

A DENTAL CURRICULUM.

Not all the Universities provide a complete dental curriculum, and Glasgow University is among those which do not. Looking to this fact, the Governors of Anderson's College Medical School, situated close to the University, have now made additions to their staff of lecturers, with the result of providing a full dental curriculum. The new appointments made are of Prof. Carstairs C. Douglas as Lecturer on Dental Bacteriology; Dr. W. Ferguson Mackenzie as Lecturer on Dental Anatomy; Dr. John Watt as Lecturer on Dental Surgery; and Mr. Charles Read as Lecturer on Dental Metallurgy.

A MEDICAL LADY MILITANT.

Dr. Elizabeth Dorothea Chalmers Smith, who, along with another lady, is accused of having broken into a Glasgow West-end mansion with the intention of burning it, appeared, with her fellow-accused, before the Sheriff on October 4th. Both ladies refused to approach the dock, but answered from the body of the Court. They declined, however, to plead guilty or not guilty. They will be tried on October 15th, at a sitting in Glasgow of the High Court of Justiciary. Mrs. Smith is the wife of a well-known Glasgow clergyman.

THE BREATHING MECHANISM IN DIVING.

Prof. D. Noel Paton, at the opening of the Session of the Royal Philosophical Society of Glasgow on October 8th, delivered a lecture on this subject. He first referred to the very different power of enduring submergence shown by different animals and by different persons, and to the influence of practice in increasing this power. He pointed out that to prevent drowning in submergence the breathing must be stopped, so that the water is not sucked into the lungs, and a supply of oxygen must be secured by storing air in the body or by storing oxygen in the blood. A man by deep and rapid breathing can so clear out the carbonic acid—the normal stimulator of respiration—from his body that a condition of apnœa —absence of breathing—lasting in some individuals for as much as three or four minutes, may be produced, and if at the same time he saturates his body with oxygen by one or two inhalations of that gas, he may be able to hold his breath for as much as eight minutes. In ducks the power of sustaining submergence is peculiarly well developed: they stop breathing and remain in a state of apnœa.

Dr. James H. Macdonald, of the Govan District Asylum, Hawkhead, has been appointed Mackintosh Lecturer in Psychological Medicine in Glasgow University.

BELFAST.

BENN ULSTER EYE, EAR AND THROAT HOSPITAL, BELFAST.

AT a meeting of the Executive Committee of the above institution a hearty vote of thanks was conveyed to Mr. Henry Hanna, M.B., B.Sc., M.A., on his resignation of the post of Assistant Surgeon, for his services during his tenure of office. Mr. Hanna has been appointed Surgeon to the Eye, Ear and Throat department of the Union Infirmary in the place of Mr. James Craig, F.R.C.S.Eng., who succeeds the late Dr. Shaw as Lecturer on Ophthalmology at the Queen's University of Belfast. Dr. F. C. Smyth, who has for some years acted as Honorary Anæsthetist to the Benn Hospital, has also resigned, and a similar compliment was accorded to him by the Committee. Dr. Isaac Davidson has been appointed to succeed Mr. Hanna, and Dr. W. A. Anderson has been appointed an additional Assistant Surgeon. Dr. H. Norman Barnett has been appointed Anæsthetist in the room of Dr. F. C. Smyth.

ROYAL VICTORIA HOSPITAL.—THE KING EDWARD MEMORIAL.

This memorial to the late King is to take the form of additional buildings for the accommodation of the Electrical Department and the Department of Hæmatology and Serum Therapy. The plans have now been passed, and the work is to begin immediately, It is expected that the new buildings will be completed in eighteen months' time. The Winter Session at the Royal Victoria Hospital will be inaugurated by an opening lecture by Dr. Rankin, Assistant Physician in Charge of the Electrical Department, on the 14th inst. The new buildings on the medical side of the Queen's University are now practically completed, and it is expected that they will be opened during the coming session. The Anatomy Department will, when completed, be one of the best in the kingdom.

The Abbey Sanatorium, Whiteabbey.

At a meeting of the Belfast Board of Guardians, held on the 7th inst., Dr. Robert Hall, Senior Medical Officer of the Sanatorium, reported that the Right Hon. Sir Henry Robinson, Vice-President of the Local Government Board, had recently visited the Institution and expressed himself as pleased with everything the Guardians had done in connection with it. A letter was read from the Town Clerk stating that the Corporation had received an intimation that their scheme for the treatment of tuberculosis had been sanctioned, and that they proposed, with the concurrence of the Board of Guardians, to ask the Local Government Board to arrange for the transfer of the Sanatorium from the 1st inst. This proposal met with the cordial support of the Guardians, so that it is probable that in the near future all arrangements for the transfer of this splendid institution from the care of the Guardians to that of the Belfast Corporation will be completed.

MANCHESTER.

Dinner to Prof. Delepine.

Prof. Sheridan Delepine, Professor of Public Health and Bacteriology in the Victoria University, Manchester, was entertained to dinner at the Midland Hotel, Manchester, on Friday night, October 11th. The event marked the completion of twenty-one years' association with the University, and an address was presented to him signed by more than 200 of his former pupils, and in addition to the congratulations of those present best wishes were sent from old pupils in different parts of the globe.

Dr. Newsholme, of the Local Government Board, presided, and in his speech referred to the inspiration they owed to Prof. Delépine, and to the value they attached to his pioneer work in applying pathology to public work.

Dr. W. J. Howarth presented the address to Dr. Delépine, in which his former students expressed affectionate regard for the Professor and pride in his scientific attainments, and deep admiration of his work for Manchester University and for the students who came under his care, and set on record that "You built up a Public Health Department of which the University and City may be justly proud. It has served as a model which others have followed with advantage. Representatives of every branch of public health service are among those who are proud to have the privilege of being trained within its walls."

Dr. Coutts, proposing "Our Guest," said they admired him as a man, a scientist, a teacher, and organiser, and both in England and throughout the world many important positions as public health officers were held by his former students.

Prof. Delépine, in reply, said his aim had been to make his pupils trustworthy and efficient servants of the State by helping them to combat human suffering and to give them pleasure in honest work and the accomplishment of duty. The Manchester Public Health School had been fortunate in the qualities of the men who had passed through it. He suggested that this should be the first of many gatherings of old and new members of the school, and asked them to use their power to endow at the Manchester University a Chair of Preventive or State Medicine. He expressed satisfaction that one hundred sanitary authorities in the midst of a large population were connected with their laboratory.

Sir Edward Donner, Chairman of the Advisory Committee, expressed the great opinion he always had of Prof. Delépine, as a man of science and a man of business, and his great regard for him as a friend.

Dr James Niven, Medical Officer of Health for Manchester, described the Public Health School established by Professor Delépine as probably the finest in the country.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE DISCOVERY OF THE RADIUM-MESOTHORIUM CURE OF CHRONIC DEAFNESS OF THE HOPELESS KIND.

To the Editor of The Medical Press and Circular.

Sir,—Among the seriously inaccurate statements that have quite recently been made in the lay Press in regard to treatment by radium and radio-active agencies that alleged to have emanated from the "Medezenalen Klinik," in which Dr. Hugel, of Berlin, is credited with having discovered the curative effects of radium and mesothorium in chronic deafness, is one that cannot be allowed to pass unchallenged.

Having in October, 1908, observed and realised the curative effect of what I had provisionally termed the "ultra-X-rays" in a case of chronic deafness in a hospital out-patient, who was being treated under my directions for specific gummata of the tongue, obliquely through the open mouth; a second case that had been otologically examined and given up as hopeless being that of an acquired deaf mute, was experimentally subjected to a similar course of "ultra-X-ray" treatment, with very satisfactory results. Both cases were subsequently exhibited at the hospital clinical meetings and were duly published.

As two such exceptional experiences were not sufficiently conclusive they were subjected to the test of time, and the experiments were repeated in a few similarly hopeless deaf cases in 1909. During this year I also began to treat some with a plaque of radium bromide, which I fixed over the mastoid process, and later the radio-active mineral autunite was introduced into the meatus in one centigramme metal capsules. In April, 1910, I brought forward two of the originally deaf patients, before the Neurological Section of the Royal Society of Medicine, in order to illustrate what I then termed the neurogenetic effect or amœboidism induced by these radiations in nerve terminals. Owing to the large number of cases that were exhibited on that occasion, the exhibition of mine was unavoidably deferred.

This experimental research was, however, continued without intermission, in spite of the obstacles that presented themselves. By August, 1912, having had a large and convincing experience, I submitted the notes of a few of these cases to the *Lancet*. The Editor courteously replied in returning my notes, and suggested that my cases had better be exhibited and discussed at one of the medical societies before publication. Accordingly, in November, 1912, the notes of my eight earliest cases (five of which were originally deaf mutes) were submitted to the President of the Otological Section of the Royal Society of Medicine. After a few days, he expressed his interest in the notes, and kindly offered to introduce me to the meeting when the time arrived. Not being an otologist or a member of that section, I was informed that the notes would first have the consideration of the Council before a date could be fixed for their discussion. This date was finally fixed for the 21st February, 1913, three months later.

At the eleventh hour, however, after the circulation of the notes on the agenda paper of the meeting, certain of the members of that section raised a protest to the President, threatening to resign and form another otological society if my cases were examined or discussed. The President, under these circumstances, reluctantly complied with their demands, and I was requested to cancel by wire my invitations to my patients; but this I could not bring myself to do; the patients were there, also a few medical men concerned in them, but they were not examined or discussed to the consternation of many. I had the honour, however, of introducing some to the President.

Since this incident in the research, that matter has been in the hands of my legal advisers. The experiments were continued, and in June last, at the invitation of the British Oto-laryngological Society, I was able to exhibit four further cases that had been otologically tested both before and after a four months' course of treatment. A report was published in the Medical Press and Circular, July 23rd, and in the *Lancet* of the 26th July last, in page 223, which speaks for itself. For this kind of aid I desire to thank the Fellows of this Society.

As to the identical relationship of the radiations emanating from the radium and mesothorium, with those from such a Crookes tube, to the discharges from which I have provisionally applied the term "ultra-X," may be questioned by some practitioners; permit me to describe that association briefly. Radium and mesothorium are elements both of which discharge the long beta and the gamma radiations, the "surpenetrans" of Dominici, but the enclosing metal or filter that is used to cut off the inevitable short radiations that damage the skin structures, has, set up within the molecules of the metal, new secondary radiations of short length, the action of which has also to be provided against by more dense covering; other factors need not here be mentioned. A Crookes tube that becomes useless for superficial therapeutic purposes, after repeated regenerations, the vacuum being now very high, it ceases to discharge the short radiations, though the long beta and gamma radiations continue to be discharged for some time longer with proper management, while using a heavy current and a spark gap of from ten to twelve inches. At this stage there is no difference therapeutically between these types of radiations from the sources under consideration. There is no primary necessity for protecting the skin from the action of these ultra-X rays. No metal filter being applied to the skin, there are no secondary radiations generated at the skin. An aluminium filter or thick leather disc is used in the path of the rays, at some distance from the skin surface, as a precaution against the occasional softening of the tube by heat at the anode when the cooling device fails. This valuable deep therapeutic feature of a high Crookes tube has not been known to medical science hitherto.

I am anxious to invite discussion which may help us nearer to the truth which we are all seeking.

I am, Sir, yours truly,
H. D. McCulloch.

77, Gloucester Place, Portman Square, W.,
October 7th, 1913.

MEDICAL MEN UNDER THE INSURANCE ACT.

To the Editor of The Medical Press and Circular.

Dear Sir,—In a letter you did me the honour to publish in your issue of September 17th, I said we panel doctors were slaves. Does not the Liverpool case (Dr. Duncan's) prove that we are worse than slaves—i.e., have to suffer for the negligence of others. The Manchester statistics (which I had hoped you would comment on) prove the inadequacy of the remuneration. Yours, etc.

London, S.W. An Old Radical.
October 12th, 1913.

A PRACTICAL CONSIDERATION OF VACCINE THERAPY.

To the Editor of The Medical Press and Circular.

Sir,—I find in Dr. Wyatt Wingrave's interesting lecture on "A Practical Consideration of Vaccine Therapy," reported in your issue of October 8th, the following passage: "Take the case of the dog licking his sores; he is practically giving himself an autovaccine, and a very good one, too. He is licking up the bacteria from his wound and killing them by probably the acidity of his stomach; the endo-toxins are liberated in his stomach and bowels, they are absorbed by the blood and then set up an immunity."

What I would like to ask Dr. Wingrave is, how is it, if this is the case, that the swallowing of pus in cases of pyorrhœa, chronic discharging abscess of the mouth, etc., are productive of such serious constitutional results?

Surely, if we may reason by analogy, in the face of what Dr. Wingrave tells us to be the case, quite a contrary effect should be anticipated.

Yours faithfully,
Wm. M. Gabriel, M.R.C.S., L.D.S.Eng.

72, Ludgate Hill, London, E.C.
October 9th, 1913.

OBITUARY.

DR. JOHN MACMILLAN, OF EDINBURGH.

By the death of John Macmillan, which took place on October 7th, the medical profession has lost a man of varied attainments and high abilities. Dr. Macmillan entered the medical profession somewhat late in life, after his youth had been passed as a teacher of mathematics. He was an M.A. of St. Andrews, and in 1879 took the degree of B.Sc. at Edinburgh. He did not, however, graduate in medicine until 1892; he was a Fellow of both the Royal Colleges, and also a D.Sc. and a holder of the D.P.H. Owing perhaps to a too retiring disposition, and also to the delay in beginning medicine, he hardly met with that success in practice to which his merits entitled him. His reward was rather in the universal esteem of his fellows, and in the recognition which he gained as a teacher. He was an examiner in Biology in the College of Physicians, and a lecturer on medical jurisprudence. He had studied in Paris, Vienna, Berlin, and Jena, and was a man of wide and extensive culture. Some years ago he underwent a serious operation, and for a long time he appeared to have made a good recovery. Latterly, however, he had visibly failed, and although he was at his regular work until a few days before his death, his health had aroused the anxiety of his friends. He passed away peacefully after but a day or two's confinement to the house. Macmillan was a man of urbane and kindly disposition. Troubles passed lightly over his head; he had a friendly nod and greeting for all. He was a man whom all liked and respected, and who had not an enemy. He was unmarried.

LIEUT.-COL. J. RITCHIE.

We regret to announce the death of Lieutenant-Colonel John Ritchie, R.A.M.C., M.B., C.M., of 6 Glenan Gardens, Helensburgh, which took place on October 6th at a nursing home in Glasgow as the result of injuries he received through falling over an embankment at Blantyre Priory, near Uddingston, on the 4th inst. He saw considerable service in the South African War. Born in 1862, Colonel Ritchie was educated at Glasgow University, where he took the M.B. in 1884. He became Captain in the Royal Army Medical Corps three years later, and in 1898 went out to West Africa, where he saw service. In 1898-9 he was present at the operations in Sierra Leone, and received the medal with clasp. During the South African War he took part in the operations in the Orange Free State in April and May, 1900, and subsequently in the operations in the Transvaal, including the actions near Johannesburg, Pretoria, and Diamond Hill. Later in the same year, 1900, he was engaged in the operations in the Orange River Colony, including the actions at Wittebergen in July, and afterwards in Cape Colony, south of Orange River, and again in the Transvaal from March, 1901, to May, 1902. For these services he was awarded the Queen's medal with four clasps and the King's medal with two clasps. Colonel Ritchie contributed an article on "The Fevers of West Africa" to the *Glasgow Medical Journal* in 1898, and also wrote on his experiences in the South African War.

Medical News in Brief.

Central London Throat and Ear Hospital.

The winter session at the Central London Throat and Ear Hospital, Gray's Inn Road, W.C. will commence on Friday, October 17th, when Dr. Thomas James Walker will deliver the inaugural address, "Laryngoscopy 1860 to 1913—A Retrospect," at 3 p.m. The annual dinner of the staff with past and present students will take place the same evening at the Trocadero Restaurant, Dr. Dan McKenzie in the chair.

The Royal Medical Benevolent Fund.

Dr. Norman Porritt, of Huddersfield, Hon. Treasurer of the Society of Medical Phonographers, has forwarded on behalf of that Society a cheque for £7 7s. towards the funds of the Royal Medical Benevolent Fund.

Royal College of Surgeons of England.

The following demonstrations of specimens in the Museum will be given in the theatre of the College in Lincoln's Inn Fields. The demonstrations are intended for advanced students and medical practitioners—

Friday, October 17th, 5 p.m., Professor Keith.—Specimens illustrating the lesions of Anchondroplasia, Osteogenesis imperfecta, and allied conditions.

Monday, October 20th, 5 p.m., Mr. Shattock.—Specimens illustrating Fibroma.

Wednesday, October 22nd, 5.30 p.m., Mr. Colyer.—Specimens illustrating irregularities of the teeth in animals.

Friday, October 24th, 5 p.m., Professor Keith.—Specimens illustrating anatomical and pathogical conditions of the Great Bowel in cases of Intestinal Stasis.

Monday October 27th, 5 p.m., Mr. Shattock.—Specimens illustrating Myxoma and Chondroma.

Wednesday, October 29th, 5.30 p.m., Mr. Colyer.—Specimens illustrating irregularities of the teeth in man.

Friday, October 31st, 5 p.m., Professor Keith.—Specimens illustrating certain points in the anatomy and physiology of the Ear.

Monday, November 3rd, 5 p.m., Mr. Shattock.—Specimens illustrating osteoplastic inflammation of bone.

University of Edinburgh.

The following candidates have passed in chemistry of the first professional examination:—William Bald, Philip Barlow, Geoffrey P. Burns, Norman A. Doggart, M.A., Ajah S. Garewal. Francis Gunaratna, Edward S. Jackson, Norman Jennings , Robert MacGarrol, Alister R. Matheson, Samuel D. Nurse, Jossel Riesnik, Susan A. Robertson, Mary J. D. Rutherford, Raymond B. Smith, James A. Stirling.

The following candidates have passed in anatomy of the second professional examination—Willian W. Brown, Alexander Cleland, W. Haig Ferguson, Arthur B. Grant, William N. Greer, Thomas L. P. Harries, Wilhelmina W. Hendry. Arthur N. Homewood, William L. Hunter. Maurice K. Jardine, Charles M'Donald, John M'Garrity, Margaret M. M'Garrity, Ian Mackenzie. Ronald N. Mackenzie, Patrick D. M'Laren, M. A., Isobel M. M'Lullich, Donald A. Macrae, W. G. F. Owen Morris, Donald J. Morrison, George Nicholson, John O. Reid, Gokal C. Sahgal, John Sellar, John J. Shannon, Wm. A. Slack, Mukundrai D. Thakoro, Jacob I. de Villiers, Gladys Ward, Gladys R. M. V. Williamson, Colend M. M. Zubair.

The following candidates have passed in physiology of the second professional examination:—George S. Barnett, Demetrio Colombos, Kshirendra M. Dev, Sergoi I. Dmitrieff, Peter W. Edwards, William N. Greer, Thomas L. P. Harries, Francois J. Hauptfleisch, Jane E. Hay, Wilhelmina W. Hendry, Alexander Kennedy, Aubrey C. Kirton, Isobel M. M'Lullich, Annie M. Madin, Isabella Morison, Donald J. Morrison, Joseph E. Phillips, Gokal C. Sahgal, Ernest O. A. Singer, Erik D. Söderströn, Clement I. Stockley, George W. C. Sutherland, Mukundrai D. Thakore, Andre F. de Waal.

Royal Colleges of Physicians and Surgeons of Edinburgh, and Royal Faculty of Physicians and Surgeons of Glasgow.

The following candidates having passed the requisite examinations of the above Board in October, were admitted Diplomates in Public Health:—Alexander D. Campbell, M.B., Ch.B.Ed., Gurudas Ram Vohra, L.R.C.P. and S.E., etc; Charles Cameron, M.B., Ch.B.Edin.; William A. Muir, M.B., Ch.B.Glasg.; Narain Rama Rao Ubhaya, L.R.C.P. and S.E., etc.; Andrew Campbell, M.B., Ch.B.Ed.; Gordon G. Jolly, M.B., Ch.B.Ed.; William S. McLaren, M.B., Ch.B.Ed.; James D. Saner, M.B., C.M.Ed.; Mangalore Laxumana, Bangara, M.B., Ch.B.Ed.; George Richardson, M.D., etc., Ed.; Alexander G. Ingram, M.B., C.M.Aberd.; and John A. MacLeod, M.B., Ch.B.Ed.

Edinburgh Royal Infirmary.

At a meeting of the managers of the Edinburgh Royal Infirmary held on the 6th inst., Mr. A. A. Scot Skirving, F.R.C.S.Ed., and Mr. George L. Chiene, F.R.C.S.Ed., assistant surgeons, were reappointed for further periods of five years each as from December 7th next. The following appointments were made for the ensuing winter and summer sessions:—Clinical Tutors—A. G. Henderson, M.B., Ch.B., to Dr. Graham Brown; H. W. Boreham, M.B., Ch.B., to Dr. W. G. Sym; E. H. Cameron, M.B., Ch.B., to Dr. J. V. Paterson. Clinical Tutors and Supervisors of the Administration of Anæsthetics—John M. Darling, F.R.C.S.Ed., to Mr. Cathcart; A. Pirie Watson, F.R.C.S.Ed., to Professor Thomson. Supervisor of the Administration of Anæsthetics—F. D. Cairns, M.B., Ch.B., to Dr. Barbour. Instructor in Anæsthesia—D. C. A. M'Alum, M.B.C.M., to Professor Caird.

Royal Academy of Medicine in Ireland.

At the annual general meeting of the Royal Academy of Medicine in Ireland, held in the Royal College of Surgeons last Friday, the following officers were elected for the coming year:—President, *Walter G. Smith; General Secretary, *J. Alfred Scott; Secretary for Foreign Correspondence, *Sir John Moore.

Medical Section.—President, J. O'Carroll—Council—1 W. Boxwell; 2 *H. C. Drury; 3 *J. Lumsden, 4 G. E. Nesbitt, 5 *J. A. Matson, 6 *Sir J. Moore, 7 *T. G. Moorhead, 8 *G. Peacocke, 9 *F. C. Purser, 10 *W. A. Winter.

Surgical Section.—President, R. D. Purefoy, P.R.C.S.—Council—1 *C. A. Ball, 2 *A. Blayney, 3 *L. G. Gunn, 4 *W. S. Haughton, 5 *R. C. B. Maunsell, 6 A. A. McConnell, 7 *W. Pearson, 8 *S. Pringle, 9 *R. A. Stoney, 10 *W. I. de C. Wheeler.

Obstetrical Section.—President. M. J. Gibson—Council—1 *G. FitzGibbon, 2 Sir A. Horne, 3 H. Jellett, 4 *T. Neill, 5 *R. D. Purefoy, 6 *J. S. Sheill, 7 *B. A. Solomons, 8 *Sir W. Smyly, 9 *A. Smith, 10 *E. H. Tweedy.

Pathological Section.—President J. B. Coleman—Council—1 *W. Boxwell, 2 R. M. Brontë, 3 *L. G. Gunn, 4 *W. G. Harvey, 6 *T. T. O'Farrell, 7 *W. D. O'Kelly, 8 *R. J. Rowlette, 9 *A. H. White, 10 J. T. Wigham, 11 *A. Wynne.

Section of Anatomy and Physiology.—President. B. J. Collingwood—Council—1 *W. M. Crofton, 2 *A. F. Dixon, 3 * T. P. C. Kirkpatrick, 4 *A. A. McConnell,, 5 *E. P. McLouglin.

Section of State Medicine.—President, T. P. C. Kirkpatrick—Council—1 *A. E. Boyd, 2 *W. M. Crofton, 3 J. Lumsden, 4 *J. A. Matson, 5 R. J. Rowlette, 6 *W. A. Winter.

Candidates marked (*) are outgoing officers who seek re-election.

Prof. William Stirling, M.D., F.R.S.E., will deliver the Lady Priestley Memorial Lecture under the auspices of the National Health Society on November 27th, at the Royal Society of Medicine.

NOTICES TO CORRESPONDENTS, &c.

☛ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

DR S. R. (London, W.).—Ervasin is acetyl-para-creosotic acid, which is a homologue of acetyl-salicylic acid. It has been successfully used in the treatment of acute articular rheumatism.

L.R.C.P.EDIN. (Hants).—We could not advise salvarsan in any case where there is suspicion of renal disease. Mercurial treatment would, no doubt, be better tolerated.

BURSLEM.—The claim appears to us to be too indefinite to be sustained in a court of law. Unless our correspondent is prepared to incur heavy costs in the event of being non-suited, the risk of an action is scarcely advisable.

THE GUILD OF ST. LUKE FOR MEDICAL MEN.

THE annual service of the Guild of St. Luke will be held in St. Paul's Cathedral on Tuesday, October 21st, at 7.30 p.m., when the preacher will be the Rev. Canon Arnott, F.R.C.S., rector of Beckenham. The offerings, after the expenses of the service have been defrayed, will be for the missionary funds of the Guild. Tickets of admission can be obtained by sending a stamped addressed envelope to the Provost, Mr. George Cowell, F.R.C.S., 24 Harrington Gardens, S.W.

S. V. T. (Leeds).—The theory of the possible causation of new growths through the presence in excess of hormone, is one to which the attention of our correspondent might be directed.

CLUB DOCTOR.—It is now generally agreed that the main, if not the only, factor in the causation of miners' nystagmus is feeble illumination. For this the safety lamp is responsible. In pits in which candles are permissible, the defect is almost unknown among the colliers. The most recent work on the subject is "Das Augenzittern der Bergleute," by J. Ohm, published in Leipzig, an English translation of which, has so far, not been prepared.

OMEGA.—No information has reached us with reference to the report in question.

Meetings of the Societies, Lectures, &c.

THURSDAY, OCTOBER 16TH

ROYAL SOCIETY OF MEDICINE (SECTION OF DERMATOLOGY) (1 Wimpole Street, W.).—5 p.m.: Cases by Dr. Haldin Davis, Dr. Knowsley Sibley, Dr. J. M. H. MacLeod, and others.

FRIDAY, OCTOBER 17TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF OTOLOGY) (1 Wimpole Street, W.).—5 p.m.: Cases by Mr. W. M. Mollison, Mr. Sydney Scott, and others.

ROYAL SOCIETY OF MEDICINE (SECTION OF ELECTRO-THERAPEUTICS) (1 Wimpole Street, W.).—8.30 p.m.: Clinical Evening. Members are invited to bring Specimens, Cases, or Plates.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—5 p.m.: Prof. Keith. (Museum Demonstration.)

Appointments.

COOKE, H. W., L.R.C.P.Lond., M.R.C.S., Resident Obstetric Officer at the Bristol Royal Infirmary.

ESKELL, BERTIE CECIL, M.B., Ch.B.Bristol, Honorary Assistant Anæsthetist at the Bristol Royal Infirmary.

HENDERSON, JOHN, M.D., Ch.B.Glasg., F.R.F.P.S.Glasg., Professor of Medicine in St. Mungo's College, Glasgow.

KAY, C. W., L.R.C.P. and S.Edin., L.F.P.S.Glasg., Certifying Surgeon under the Factory and Workshop Acts for the Lymington District of the county of Southampton.

KERR, ROBERT ANDREW, M.B., B.Ch., B.A.O.Belf., House Surgeon at the Bristol Royal Infirmary.

O'SHAUGHNESSY, E., L.R.C.P. and S.Edin., L.F.P.S.Glasg., Certifying Surgeon under the Factory and Workshop Acts for the Broadford District of the county of Limerick.

PARKER, GEORGE, M.D.Cantab., Sole Lecturer in Forensic Medicine and Toxicology at the University of Bristol.

SALISBURY, W., M.B., B.S.Lond., House Surgeon at the Bristol Royal Infirmary.

SNODGRASS, J. E., M.B., Ch.B.Edin., Certifying Surgeon under the Factory and Workshop Acts for the Raphoe District of the county of Donegal.

SPENCER, GORDON WINSTANLEY, M.B., B.C.Cantab., L.R.C.P.Lond., M.R.C.S., House Physician at the Bristol Royal Infirmary.

STATHAM, REGINALD SAMUEL SHERRARD, M.D., Ch.B.Bristol, Registrar to Special Departments at the Bristol Royal Infirmary.

STRATON, ARTHUR A., M.B., B.S.Lond., Clinical Assistant to the Chelsea Hospital for Women.

Vacancies.

Manchester Schools for Mothers.—Medical Officer. Salary £250 per annum. Applications to the Hon. Secretary, Medical Sub-committee, 339 Oxford Road, Manchester.

Down District Lunatic Asylum.—Junior Male Assistant Medical Officer. Salary £130 per annum, rising by annual increments to £150 per annum, with full board, washing, apartments, and attendance. Immediate application. (See advt.)

Mercer's Hospital.—Hon. Visiting Physician. Applications to the Registrar. (See advt.)

County Borough of Belfast.—Chief Tuberculosis (Medical) Officer. Salary £600 per annum. Applications on or before October 23rd to the Town Clerk. (See advt.)

Northampton County Asylum, Berry Wood, Northampton.—Junior Assistant Medical Officer. Salary £200 per annum, with board, lodging, and washing. Applications to Medical Superintendent.

Wakefield General Hospital.—Second House Surgeon Salary £100 per annum, with board, lodging, and washing. Applications to the Hon. Secretary, Clayton Hospital, Wakefield.

Lewes Victoria Hospital.—Resident Medical Officer. Salary £120 per annum, furnished apartments, board, coal, gas, washing, and attendance. Applications to the Hon. Secretary.

Leyton, Walthamstow, and Wanstead Children's and General Hospital.—Resident House Surgeon. Salary £100 per annum, with rooms, board, and washing. Applications to James Bird, Secretary, The Hospital, Orford Road, Walthamstow, N.E.

Bury Infirmary.—Junior House Surgeon. Salary £100 per annum, with board, residence, and washing. Applications to the Hon. Secretary, Infirmary, Bury, Lancs.

North Lonsdale Hospital, Barrow-in-Furness.—Junior House Surgeon. Salary £100 per annum, with board, residence, and washing. Applications to the Secretary.

Hereford County and City Asylum.—Junior Assistant Medical Officer. Salary £200 per annum, all found. Applications to the Medical Superintendent, The Asylum, Burghill, Hereford.

Births.

FRANKLIN.—On September 15th, at Wadhurst House, Newington Green, London, N., the wife of Reginald Franklin, L.R.C.P.Lond., M.R.C.S.Eng., of a son.

GAYNER.—On October 8th, at Red Hill, Surrey, the wife of Dr. Francis Gayner, of a daughter.

SARGENT.—On October 9th, at 20 Harley Street, W., the wife of Percy Sargent, F.R.C.S., of a son.

Marriages.

ATKINSON—SHIELD.—On October 7th, at Holy Trinity, Paddington, Dr. Arthur William Atkinson, M.B., C.M., son of Dr. James Atkinson, M.R.C.S., L.R.C.P., J.P., Mirion House, Crewe, to Winifred, daughter of William Shield, M.Inst.C.E., Clapham Common.

GIBSON—KENNEDY.—On October 4th, at St. Matthew's Church, Ealing Common, Alfred John Gibson, M.B., B.S., of Brentwood, Essex, son of Alfred Gibson, Esq., to Elma Mary, only daughter of C. Fred Kennedy, Esq., Madely Road, Ealing.

GOFF—GARRETT.—On October 8th, at Woodburn Hamilton, John Goff, M.D., Bothwell, to Sophia, youngest daughter of James Garratt, of Dundalk, Ireland.

PEARCE GOULD—RHYS-GRIFFITHS.—On October 8th, at the Parish Church of St. John the Baptist, Cardiff, Hugh, eldest son of Sir Alfred Pearce Gould, K.C.V.O., M.S., of 10 Queen Anne Street, London, to Enid, elder daughter of Dr. and Mrs. Rhys-Griffiths, of 50 Newport Road, Cardiff.

Deaths.

DIXON.—On October 9th, at Oulton Lodge, Oulton Broad, Ellen, the beloved wife of William Edward Dixon, F.R.C.S.

GOURLEY.—On October 4th, at Linden Villa, Gosforth, Harry Harte Gourley, M.D.Durh., L.R.C.P. and S.Edin., L.F.P.S.Glasg.

JACKSON.—On October 10th, John Lowthian Jackson, M.D., of Hedon, East Yorks, aged 53 years.

RITCHIE.—On October 6th, suddenly, at a Nursing Home, Glasgow, John Ritchie, M.B., C.M., in his 51st year, Lt.-Colonel R.A.M.C., of 6 Glenan Gardens, Helensburgh, beloved husband of Marion Weir Burden Ritchie.

SWALLOW.—On October 11th, at his residence, Clifton Lodge, Clarence Road, Clapham Park, S.W., James Dodd Swallow, M.D., in his 78th year.

WATSON.—On October 5th, at Ladysmith, Cape Colony, Robert Walker Watson, M.R.C.S., second son of the late John Watson, of Dyers' Hall, E.C., and of Mrs. Watson, 42 Manor Road, Beckenham, Kent.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVII. WEDNESDAY, OCTOBER 22, 1913. NO. 17.

NOTES AND COMMENTS.

Paying Patients in Voluntary Hospitals.

THE announcement that some of the empty wards at Charing Cross Hospital are to be thrown open to paying patients raises the old discussion as to the economic justice of such a proceeding. From the point of view of the management of the hospital the step is justifiable in the interests of the public as well as of the institution. Some years ago the Board took upon its shoulders an enormous additional responsibility in the extension and rebuilding of its premises. Its finances are still staggering under a heavy burden of debt. Under such circumstances it is only natural that the management should look round for some means of filling empty wards, and at the same time of increasing funds. What readier means could be at hand than to follow the example of such wealthy and influential hospitals as Guy's and St. Thomas's—not to mention many institutions of lesser note—who receive paying patients? The grievance about the abuse of hospitals is one of old standing, and it was raised mainly against the *gratis* treatment of all kinds of minor ailments in the out-patient department of the voluntary charities, regardless of the ability of the patients to pay the fees of the outside private practitioner. For some time past the agitation against hospital abuse has died away, and there is no reason to suppose that it would be raised again against the system of payment for in-patients, especially as the profession had tolerated for so long the competition of hospital private wards of Guy's and St. Thomas's.

Is the Pay System Legal in Hospitals?

THE pay wards make a bid for patients of a class that do not frequent out-patient departments. They are able to pay two or three to six guineas a week, and often, in addition, to pay the fees of the superintendent of the "Home," or of the member of the staff who may attend them. A bald statement of the situation is that the private practitioner loses a valuable patient owing to the competitive bid of the hospital. As to the legal aspects of the transaction, it seems not unlikely that an injunction could be obtained against any hospital that devoted its funds to the purpose of making money out of patients. The matter would hinge on the exact wording of the constitution of the hospital concerned. If there were any clause permitting it to trade—for that is the net result of the pay system—upon funds given for the definite purpose of the relief of the sick poor, any protest could be safely disregarded. It may be doubted, however, if any great voluntary charity has such a proviso in its rules and regulations. From a single legal standpoint, to apply charitable funds to the making of profit is a malversation—to use the jargon of the lawyers. Were there any body of medical practitioners strong enough and united enough to raise the point, it seems probable that an injunction could be obtained in the High Courts restraining Charing Cross or any other voluntary medical charity from receiving patients' payments. Query: Does a voluntary charity cease to be a charity when it takes monetary payments for its services—and what about the subscribers whose money was contributed definitely for other purposes?

The Supporters of the Pay System.

THE managers of a hospital receiving payments for in-patients would in all probability deny indignantly that they were competing with outside medical practitioners. It would be very interesting to learn by what process of reasoning they would support that denial. The reasons advanced by the supporters of the pay system are for the most part general and evasive. It would be interesting to get a brief statement of their position from some authority on the matter—such as Sir Henry Burdett—who has been a life-long protagonist of the pay system. The chief points which should be clearly dealt with are the competition with the outside medical profession, the diversion of voluntary subscriptions, the desirability of medical men attached to the charity, either in a salaried or honorary capacity, acting as medical attendants upon private paying patients. What has the Board of Charing Cross Hospital to say about the matter? What are the views of the King Edward and the Metropolitan Hospital Sunday and Saturday Funds? Have they any definite policy? Surely if they have accepted so heavy a responsibility as the distribution of money given for purely charitable purposes they ought to have decided views as to its application in alien directions. Considering the huge sums that are raised annually for the medical charities, it is a matter of regret that some of the largest and wealthiest of those insitutions should seek to add a relatively small sum to their incomes by adopting a system which can never be anything but distasteful to a large proportion of the medical profession.

Prosecution of Queen's Square Hospital.

THE control of cinematograph performances is clearly a right and proper proceeding in the interests of the public safety. The occurrence of fire or explosion has on various occasions thrown audiences into a panic with disastrously fatal results. There comes an element of Rabelaisian humour, however, when the whole artillery of administrative law is directed against a private cinematograph demonstration to the learned members of the International Congress of Medicine. Such an anti-climax has fallen upon the Secretary of the Queen's Square Hospital for the Paralysed and Epileptic. It was contended by the police prosecutor that the premises of that famous hospital had been used in contravention to the regulations made by the Secretary of State under the Cinematograph Act, 1909. It was proved in evidence that the films were inflammable; there were three exits to the room, but they were not specially indicated; the apparatus was not enclosed, and the films were not kept in a metal box. The defence pleaded in vain that the demonstration was attended solely by post-graduate students and members of the Congress, and that it was not an ordinary performance. It was contended that the case came within the terms of the Sub-section which stated that the Act did not apply to a cinematograph performance in a private dwelling house to which the public were not admitted. The magistrate, however, said he could not hold the performance was given in a private dwelling, and inflicted fines and costs amounting in all to £8 5s.

Southwark versus Camberwell.

A truce appears to have been called for the time being between the adjoining Councils of Southwark and Camberwell. Possibly the advent of October, and the consequent lessening of the flies, furnishes an explanation of the silence. Southwark may be congratulated on having joined the ranks of the health enthusiasts, especially with so good a case as the conveyance by flies of germs from Camberwell's filthy railway trucks of refuse, placed within a stone's throw of her neighbour's infirmary. The lame defence, apparently good enough for the Local Government Board, is that there is no direct proof of the fatal cases of enteritis in the infirmary being due to the Camberwell garbage! By the way, where is the coroner for the district? Has he held inquests upon the cases, and, if so, with what result? Southwark might get evidence enough even to satisfy Mr. John Burns from a series of inquests. The cases should be carefully, fully, and deliberately investigated in open court, and the opinion of the jury taken as to the part played by the Camberwell refuse, the flies, the enteritis, the local authorities concerned, and the L.G.B.

LEADING ARTICLES.

MEDICAL MEN AND LAY NOTICES.

The unwritten laws of the medical profession have gradually become fashioned into a code that plays an important part in the control of ethical conduct. From the circumstances of the case they cannot be reduced to any form of accurate expression, a fact that clearly leaves the door open to a widely differing interpretation of underlying principles. It may be well, therefore, in view of the individual injustice that may follow the unequal application of our ethical laws, to consider briefly some of their bearings upon contemporary medical life. For this purpose the old-standing condemnation of lay notices whether in the form of circulars, notices of strictly medical work in the public newspapers, or in various other direct and indirect ways. The General Medical Council has sternly set its face against direct advertising, and has punished many a club doctor for sending round circulars in a new district. The Council may be invited to express an opinion in set terms upon the ethics of newspaper notices, as, under present circumstances, the practice of the medical profession is simply chaotic. To take an instance, the daily newspapers throughout the United Kingdom contained notices of many of the papers read recently before the British Medical Association at Brighton. The public learned in their columns the views of Dr. So-and-so upon the value of sea bathing, of another provincial physician on alcohol in the treatment of diabetes, and so on and so forth. As a matter of fact, reporters from the leading lay newspapers were present at the sectional meetings by the invitation of the Association itself. They could be present only for one purpose—namely, to send a description of the proceedings to the lay journals of which they were the representatives. In many of the sections they discharged that function efficiently, as may be seen by consulting contemporary files of the London daily newspapers. In certain other sections the reporters were refused all information and promptly ejected when their presence was discovered. Without expressing any view as to which was the right course, it is clear that if the reporters were there by invitation of the Association they were sent to report the proceedings. If it were right to report one section it could hardly be wrong to report another. It may be assumed that the Association by issuing press tickets to leading lay journals implied tacit approval of the publication of sectional reports in public newspapers. If so, on what logical grounds could such reporters be denied information in other sections? A better instance of chaos in unwritten medical law it would be difficult to imagine. Another example may be found in the recent manifesto against syphilis signed by a great many well-known members of the medical profession. If a single medical man were to issue a public declaration regarding some particular malady, and were to sign it with his name, address and qualifications he would probably incur a considerable amount of censure. If he happened to be an inconspicuous figure in the professional world he would run a risk of being ejected from his scientific societies and from other professional bodies, and might even engage the attention of the General Medical Council. His act, indeed, would run full tilt against the traditions that have hitherto governed medical ethics. But how can that which constitutes a heinous offence in the individual be lessened or condoned by the collective publication of a group of names? In the *Morning Post* of July 2nd, 1913, was published the above-mentioned manifesto against syphilis signed by 38 members of the medical profession. In each case, one of the chief posts held by the signatory is appended to the name. We thus have the Presidents and Past-Presidents of the Royal Colleges of London and Ireland, University Professors in London, Cambridge, Belfast, Oxford and Dublin, Presidents and Ex-Presidents of the British and Irish Medical Associations, Surgeons to the Middlesex, University College, National Hospital for the Paralysed and Epileptic, to the Skin Department of the Seamen's Hospital, St. Bartholomew's, the London Lock Hospital, Guy's, the Consulting Physician for Diseases of Women to the Royal Free Hospital and so on. Scotland is represented by the Physician for Diseases of the Skin in the Royal Infirmary of Edinburgh. There can be no doubt as to the importance of the document, but why could it not have been issued under the authority—say, of the Royal Colleges or the Royal Society of Medicine. After such a step taken deliberately by so many eminent members of the medical profession, it would be inconsistent to blame any medical men of lesser light and leading who henceforth may see fit to air their views upon this or that professional matter in the columns of lay newspapers even if they append thereto any professional title or appointment. The manifesto in question constitutes in point of fact a frank abandonment of former traditions, which forbade a medical man from citing his professional posts in such a connection. Henceforth, it will hardly be surprising if a rapid extension of this innovation ensue. There is keen rivalry in all branches of the profession, and it is hardly likely that the rank and file will allow themselves to be outdone in so simple a matter as addressing the public, individually or collectively, through the medium of the lay Press. This subject is noticed in these columns with an entire absence of feeling, or even of absolute conviction as to how far it is justifiable to go in this matter of public medical statement. The legitimacy or otherwise of signed medical communications and of authorised notices in lay journals should preferably be settled one way or the other, so that impartial justice may be meted out to all members of the profession. Either let the practice be condemned, and put an end to once and for all, or let us accept with philosophical resignation those freer relations with public journalism which have been frankly adopted in some foreign countries.

CURRENT TOPICS.

Research in Mental Disease.

The desirability of carrying out carefully-controlled scientific observations in cases of mental disorder is gradually becoming recognised by most up-to-date workers in psychiatry. The older methods of treating the insane by withholding from them the practical benefits of experimental science no longer applies at the present day. Well in the front of the new movement for research in mental disease has been the City of Cardiff Mental Hospital, the fifth annual report of which for the year 1912 shows a scientific record of which any alienist might well be proud. Owing to the energy of the Medical Superintendent, Dr. Edwin Goodall, assisted by his staff who have caught his spirit of enthusiasm, several important researches have been carried through, more especially with regard to the relation between the Wassermann reaction and the blood and cerebrospinal fluid in mental disease. The results of these experiments go to show that a higher proportion of positive reactions in the blood-serum is obtained in cases of florid syphilis (including cases in the second stage) than in those of general paralysis. Further work has been in the direction of observing the agglutinating and opsonic properties of the blood serum in cases of acute mania and melancholia upon the intestinal anaerobes, *B. putrificus* and *B. enteritidis sporogenes* (Klein). The work shows that no agglutin is formed in respect of these organisms, and that such cases exhibit a lower opsonic index than do control cases. Dr. Goodall puts forward a strong plea for the appointment of a third research worker, *viz.*, a physiologist, at as early a date as possible, in order that difficult problems connected with metabolism may be elucidated. It is satisfactory to note that the high importance of the development of the scientific side of the hospital is fully appreciated by the Commissioners in Lunacy and also by the Committee of Visitors of the Hospital.

Newgenics.

Professor Karl Pearson has been writing to the *Times*. He is protesting against the popularisation of eugenics. A serious subject is being reduced to the level of a pantomime gag. Galton, who founded eugenics, suggested two steps forward consummating his ideal of improving the human race. One step was to find out how it was to be done, and the next was to interest the people and get them to do it. The halfpenny press has reversed his scheme. No one yet knows how it should be done, but everyone talks about it and some even try to put the unknown scheme into practice. Spasmodic States in America are turning out scrappy legislation, and here in England we can read about "eugenic" marriages and "eugenic" babies. For many purposes the fine idea of race betterment has become comparable with those conveyed by lodgers, kippers and a mother-in-law. This is probably because there is a tinge of sex about problems of heredity. Music hall comedians and lady novelists cannot keep away from it. "White Slave" novels have had their day, and now "eugenic" stories usurp their place in sensuous shilling covers in the less savoury bookshops. Professor Pearson's way of bringing his Frankenstein's automaton under control is by changing its name. He thinks the prying journalistic nose would miss eugenics if called "race-hygiene" or "genetics." Knowing the journalist we do not agree. The idea that eugenics is a fit subject for prurient humorists will have to be lived down. The fault is with the founders of the movement. They realised that publicity was necessary to the success of their theories, but that was no reason why they should perfect their publicity first and their theories afterwards.

Pediculosis Capitis Amongst School Children.

School medical officers and others engaged in the work of medical inspection of school children know full well the extent to which pediculosis prevails. It is positively appalling to see the gross neglect that occurs day by day whereby children, whose heads are in a state that can only be termed filthy are allowed to mix freely with others. Indeed, the testimony of the medical officers of most hospital out-patients' departments shows that a head absolutely free from nits, especially in women and girls, is quite the exception. Dr. Jacob Sobel (*a*), in a paper read at the Fourth International Congress on School Hygiene, at Buffalo, New York, last August, showed that while all other communicable diseases of the skin were on the decline, pediculosis capitis alone remained practically stationary. After eleven years of personal experience, Dr. Sobel concludes that the disease is essentially a problem of the home. In other words, it is little use trying to combat verminous heads without attending to the condition of those at home, and especially to the disinfection of combs, brushes, linen, etc. Written instructions regarding treatment are useless, whereas personal supervision and the co-operation of teachers and parents will go a long way to ridding poor children of what can only be called a standing disgrace to any civilised community. In New York the disease was more prevalent among the alien population. In London and most large cities in Great Britain, pediculosis is pretty well distributed among the children of the poor. Crude petroleum or kerosene, diluted to half-strength with olive oil, is recommended for dealing with moderately severe cases, and the mechanical removal of all nits by the careful application of sand-paper or by fine combing, is said to be better than acid solutions. Whatever means be adopted for cleansing the heads, it is imperative that re-infection should not take place.

The Medical Waiting Room.

Let us try and look at it from our patients' point of view. On a visit to his physician, the first place where the unhappy man has time to look about and pull himself together, is the waiting-room. There he tries to pick up his courage, and there he picks up his impressions of the Rhadamanthine autocrat in the next room. He hears mysterious voices and sometimes the trickling of a fluid that he fervently hopes is water—but he is not quite sure. To distract his attention from all the grisly possibilities that beset him he picks up a paper. We all know the papers. If we don't we need only go into the next room and see. There are antediluvian *Punches* and weekly illustrateds of the month before last and some 4½d. magazines that claim to be as good as the sixpenny ones. They are a dull crowd and rather crushed and soiled. It does not give a good impression. A visit to one's doctor for an ordinary man is an apprehensive time. He doesn't do it every day, and he always wants to "hear the worst." Let us put him in a fit state for what, to him, is an ordeal. A few current numbers of decent journals will make a man at home sooner than a table littered with dingy remainders. And there is one tip that is worth the trouble. Two minutes and a pot of paste will stick the cover and a couple of advertising pages together. The result is quite a good cover that will last as long as it is wanted, and that is till the next number of the magazine comes out.

Bread and Water Diet.

Most of us can remember the days when our unrighteous little souls were vexed by being relegated to the upper regions of the house, away from bright lights and company, and fed with the humiliating, yet quite wholesome, fare of bread and water. We emerged from the ordeal, sadder and wiser, no doubt, but who will say that this bread and water of affliction had not some chastening effect upon our digestion as well as upon our morals? Not even the choicest Vienna roll and the most sparkling table-water appeals to the imagination of Mr. D. Blackley, L.C.C., who submitted a special motion condemnatory of the practice of feeding refractory children with bread and water in the special schools of the London County Council at the meeting of the London Education Committee last week. It was stated that in a certain school of 34 children, there were in 13 weeks 15 cases of bread and water punishment. In the discussion which followed, it was pointed out that neither corporal punishment nor solitary confinement was now tolerated, and that discipline must be maintained in some form among refractory school children. Perhaps we may soon hear of forcible feeding having to be adopted among these young pickles! No harm can possibly accrue to a healthy child by keeping him on bread and water for 24 hours or so, though it would not be advisable to deprive him of those proximate principles of food which are conspicuously absent in such a diet for any longer period.

Examinations and Research.

Some interesting questions are raised by Sir William Osler's recent lecture on "Examinations, Examiners, and Examinees." The examination has been for more than one generation something of a fetich, though it is not so great a fetich as it was a few years ago. We now recognise its limitations as a test, and we try to supplement it by information gained from other sources as to the candidate's record, work, and ability. This is all for the good, for however competent the examiner—and a quite large proportion of examiners are definitely incompetent—an examination is not an adequate test of a man's knowledge and capability. Sir William Osler's suggestion to put greater stress on research work in the awarding of the higher professional qualifications has been vigorously challenged by Sir Rickman Godlee, and with the

---

(*a*) *New York Medical Journal*, October 4th, 1913.

challenge we have a good deal of sympathy. There is grave danger of research work becoming itself a fetich, and at the present time much labour and energy is misdirected into channels which lead to no result, either in the form of knowledge or of improved capability. We must proceed slowly.

Desperate Remedies.

THE fatal case of anthrax, referred to in our columns last week, in which salvarsan had been administered, illustrates once more the limitations of modern drug-therapy. It was most unfortunate that the patient's kidneys were not equal to the task of eliminating the salvarsan after it had already completed its bactericidal work. No signs of chronic Bright's disease were present, it is stated, during life, or else, of course, all idea of salvarsan injection would have been abandoned. The evidence of Dr. T. M. Legge, medical inspector of factories, at the concluding stage of the inquest, should go far to reassure future sufferers from anthrax, for he dwelt very fully upon the present position of our knowledge of the action of salvarsan in anthrax for the special benefit of the jury. The researches of Dr. Eurich, bacteriologist to the Anthrax Investigation Board, make it practically certain that salvarsan is the remedy *par excellence* for anthrax, because it possesses an extraordinary selective power of attacking the bacilli, both in human beings and in animals. It would be a pity if one fatal case, acknowledged to be desperate before the injection was given, were allowed to prejudice medical men, as well as the public, against the use of so selective, if dangerous, a remedy. It is, therefore, satisfactory to note that the jury found that the injection of the drug was rightly and properly carried out.

Medical Inspection of Chauffeurs.

THE desirability of a medical examination of chauffeurs does not need much arguing, once the facts of the case are realised. Several instances have been recorded of automobile drivers being found dead at their post. Recently in London the sudden unconsciousness of a motor driver led to a terrible collision. It is a self-evident proposition that the safety of the public may be seriously endangered at any moment by the sudden failure of a physically defective chauffeur. It is simply a matter of commonsense precaution, therefore, that any candidate for a licence to drive any kind of automobile should be required to pass a medical examination before being granted a certificate. At Leicester a few days since an inquest was held on the body of a chauffeur who fell down in the street and died from heart disease. The Coroner very properly pointed out that the case showed the real necessity for a medical examination of motor drivers. Had this man been driving in the busy streets of the town at the time of his death the consequences might have been serious. There is urgent need for some drastic legislation not only in this but in various other points concerned with motor traffic. The death toll in town and country has long since reached breaking strain. It is to be hoped that the Government will be induced to turn its attention to the whole matter before many moons have passed.

PERSONAL.

DR. T. B. HYSLOP delivered the Presidential Address before the Chelsea Clinical Society last night on "Clinical Psychiatry."

DR. R. C. BROWN, of Preston, has presented the Preston Grammar School, of which he was a former pupil, with a fine organ.

SURGEON-GENERAL SIR R. HAVELOCK CHARLES will present the prizes at the Royal Army Medical College, Grosvenor Road, on October 29, at 4 p.m.

SIR M. M. BHOWNAGGREE has presented to the London School of Tropical Medicine a medal to be competed for annually in memory of the late Dr. Cawas Lalcaca.

DR. J. W. NOBLE, M.D., B.C.Cantab., M.R.C.S., L.R.C.P., has been appointed Medical Superintendent of the County of Durham Sanatorium at Holywood Hall, Wolsingham, Co. Durham.

MR. W. F. BROOK, F.R.C.S., has been elected Consulting Surgeon and life Vice-President of the Swansea General Hospital upon his retirement from the active staff after twenty years' service.

MR. J. D. MALCOLM, M.B.Edin., F.R.C.S.Edin., of London, has been awarded the Liston Victoria Jubilee Prize of £100, awarded by the Royal College of Surgeons of Edinburgh, for his investigation into the causes of shock.

ACTING-SURGEON A. M. HENRY, of Guy's Hospital, has been awarded the gold medal for the best total of marks obtained on entry at Greenwich and Haslar, and also a prize for the highest marks at the Greenwich examination.

THE MAHARANEE HOLKAR OF INDORE visited the Hampstead and North-West London Hospital last week, and, after inspecting the wards and the operating theatre, gave a donation of £25 for the purchase of an additional instrument cabinet.

AT a meeting of the Council of the King Edward VII. Welsh National Memorial held at Shrewsbury last week, Dr. Gaffikin, Belfast, Dr. J. H. P. Graham, Wallasey, and Dr. Evan D. Richards, London, were appointed Assistant Tuberculosis Physicians.

SIR ALFRED PEARCE GOULD, K.C.V.O., Dean of the Medical Faculty of the University of London, will preside in the Post-Graduate College, West London Hospital, on Thursday, October 30th, at 5 p.m., when an address will be delivered by Sir Gilbert Parker, M.P.

A COMMEMORATIVE tablet was unveiled last week at Livingstone Cottage, Hadley Green, Barnet, where Dr. Livingstone stayed in 1857 while he wrote an account of his African travels. The ceremony was performed by Mrs. Livingstone Wilson, the only surviving daughter of Dr. Livingstone.

IN succession to Sir W. Watson Cheyne, the retiring president of the Medical Society of London, Sir David Ferrier has been elected to fill the office at the annual meeting of the members. The other officers who retired were re-elected, and after the presidential address a paper dealing with facial spasms and their treatment was read by Dr. E. Farquhar Buzzard.

THE Brighton Board of Guardians last week by a large majority decided to appoint a consulting and operating surgeon for the workhouse infirmary at a fee of 100gs. per annum. This is the outcome of a deputation from the local division of the British Medical Association, who urged that Poor Law cases should no longer be treated at hospitals or other charitable institutions.

CLINICAL LECTURE
ON
PESSARIES VERSUS OPERATIONS IN THE TREATMENT OF UTERINE DISPLACEMENTS. (*a*)

By ARTHUR E. GILES, M.D., B.Sc., F.R.C.S.,

Surgeon to the Chelsea Hospital for Women; Gynæcologist to the Prince of Wales's General Hospital, Tottenham.

IN former days displacements were not treated except by the means of pessaries; and the only question to exercise the mind of the practitioner related to the kind of pessary that he was to use. Certainly, this was a large question, if we may judge from the number and variety of pessaries figured and described in the text-books of the day. Most intruments and inventions, when obsolete, are ignored and forgotten; but pessaries appear to be cherished by surgical instrument manufacturers, whose catalogues, when these appliances are concerned, read like a catalogue of museum specimens.

In the last twenty years the ingenuity of gynæcologists has been diverted from the invention of new pessaries to the devising of operations for the relief of displacements. At the beginning of this surgical era, the indications for the use of pessaries were numerous, and the indications for surgical intervention were very few. The progress of surgery in the direction of improved *technique* and diminished mortality has led to a steady encroachment of surgical procedures on the domain of pessaries, and it does not require a seer to foretell that in the course of time the original conditions will be reversed, and the indications for surgical treatment will be numerous, and the indications for pessaries will be few.

Of course, I am referring to the attitude of the profession as a whole; for just as, at any given time, there are always some ardent spirits whose ideas are in advance of their day, so there are always cautious and conservative people who lag a generation behind. In this, as in other matters, we find exemplified the proposition enunciated by the late James Hinton, that "truth lies in the polar union of opposites."

I wish now to define the relative scope of the indications for pessaries and operations from the standpoint to which my own experience has led me. Without entering upon debatable questions of ætiology and pathological anatomy, I shall include under the term "displacements" retroversion and retroflexion of the uterus, prolapse of the uterus and vaginal walls and procidentia. Moreover, since some backward displacements of the uterus cause no symptoms and are, therefore, best left alone, I may add that my observations refer only to cases in which symptoms are present from which patients must be relieved.

From the point of view of treatment I recognise three groups of displacements:—

(*a*) Cases in which there is a clear indication for pessary treatment.

(*b*) Cases in which there is a clear indication for operation.

(*c*) Optional cases, in which the patient should have both courses explained to her, and be allowed to choose.

Such divergence of opinion as is found on the subject has reference primarily to the position of the boundary lines between these groups.

A.—Cases in which there is a clear indication for pessary treatment.

In this group I should include the following cases:—

(1) Retroversion of the uterus following confinement. In many of these cases there is a temporary relaxation of ligaments and loss of tone; and the wearing of a Hodge pessary for a few months will usually bring about a cure.

Let me note in passing that when I speak of a cure in connection with displacements, I mean that the parts remain in their normal position when the pessary has been removed.

(2) Retroversion of the uterus occurring in young and nulliparous women, when the symptoms of displacement are of recent origin, and the uterus fails to keep up after simple reposition. In such cases I think that it is always advisable to try the effect of a Hodge pessary in the first instance, and give it a year's trial if necessary.

(3) Retroversion of the gravid uterus, in the early months; this is the class of case in which the patient often seeks relief on account of impaction of the retroverted uterus and retention of urine. It is usually sufficient for the pessary to be worn for six or eight weeks.

This is the only kind of retroversion in which I prefer a ring to a Hodge; the primary necessity is to keep the uterus raised up, for if raised it will not fall backwards. In cases of retroversion of the unimpregnated uterus I have hardly ever known a ring to correct the displacement. In all cases of backward displacement it is an indispensable condition that the displacement should be corrected before the pessary is introduced.

(4) Prolapse of the uterus, with or without cystocele, when the perineum is sufficiently good to hold a ring well up. If the ring is well borne, and does not readily get rough or set up vaginitis, and if it relieves the symptoms, it may be worn for a considerable time with periodical inspection; particularly if the patient is single or a widow.

(5) Cystocele without prolapse, with the same proviso as above, that the perineum is sound. Sometimes a ring answers very well; in other cases a specially-shaped pessary may be adopted, the upper end of which is like a Hodge, whilst the lower end is widened and curved forwards so as to lie behind the pubes and above the levatores ani.

(6) All kinds of mobile displacement when the condition of the patient is such as to contra-indicate operation. In this category I should include some cases of displacement in old women; although, if the patient's general condition is vigorous, I should not consider age in itself to be a bar. I have had some very satisfactory cases of operative treatment for displacement in women over seventy.

Whilst I am on the subject of pessaries, I should like to call your attention to a few popular delusions:—

That the vagina was designed by Nature as a receptacle for a pessary.

That the introduction of a pessary is good treat-

(*a*) A lecture delivered at the Medical Graduates' College and Polyclinic, October 1st, 1913.

ment as a placebo when one does not know what else to do.

That a Hodge pessary may be expected to succeed when the retroversion has not first been rectified with the fingers or sound.

That a ring is a suitable pessary for a backward displacement.

That the size and fit of a pessary are unimportant.

I now pass on to my second group.

B.—Cases in which there is a clear indication for operation.

In this category I should include the following :—

(1) All cases of backward displacement in which the uterus is fixed by adhesions, so that its position cannot be rectified. To insert a pessary in such a case is merely to add risk to inefficiency.

(2) Backward displacement complicated by ovarian tumours or inflammatory disease of the appendages. It may be said that in such a case the ovarian tumour or tubal disease, and not the displacement, is the indication for operation. With this I quite agree, but the points upon which I lay stress are that it is futile in such a case to treat the displacement by pessaries; and that when the abdomen is open one should use the opportunity to sling up the uterus if the operative conditions allow of this being done.

(3) Backward displacement complicated by one or more fibroids admitting of myomectomy. Here the fibroids may, in certain circumstances, be considered as the indication for operation; but there are also cases in which the fibroids might not be regarded, in themselves, as calling for immediate interference, and I should then regard the double condition as a clear indication for a combined myomectomy and hysteropexy.

(4) Mobile retroversion associated with a torn perineum that requires repair. While the patient is under the anæsthetic, it is a simple matter to open the abdomen and deal with the uterine displacement; it does not add materially to the operative risk; it takes very little longer; and the patient is saved from the necessity of subsequent pessary treatment.

(5) Retroversion associated with an atrophic condition of the upper part of the vagina in such a fashion as to render pessaries ineffectual.

(6) Prolapse of the uterus and vaginal walls, when the perineum is so torn or stretched that no ordinary pessary will keep in place.

(7) Total procidentia, with the vagina inverted and the uterus lying outside the vulva; particularly when associated with ulceration of the vagina due to friction of the clothes. In such cases the vaginal outlet is nearly always so stretched that pessaries fail to keep in place; and, moreover, if a pessary can be induced to stay in, it will nearly always cause excoriation and ulceration of the damaged vaginal wall.

(8) All cases of displacement when the patient is going to reside abroad in districts where medical assistance is not readily available.

(9) All cases of displacement in which a pessary rapidly perishes or becomes rough, or leads to profuse or offensive discharges, or causes inflammation or ulceration of the vaginal walls. I have met with such cases when the patient was absolutely miserable without a pessary, and yet had to do without it at frequent intervals because it was so badly borne. There has then been an alternation of (1) relative comfort, but associated with offensive discharge; and (2) freedom from discharge but with attendant discomfort and inability to retain urine when walking, coughing, or straining in any fashion.

(10) Cases of displacement in neurotic single women, on whom the concentration of attention on the pelvic organs, incidental to the wearing of a pessary, frequent douchings and periodical examinations, has a harmful mental and moral effect.

C.—Optional cases, in which the patient should have both courses explained to her, and be allowed to choose.

I place in this group cases of uncomplicated displacement, in which a pessary answers quite well as regards keeping the displacement corrected and the patient comfortable, but does not bring about a cure. As soon as the pessary is removed, the displacement returns. Consequently, there is before the patient the prospect of many years of pessary treatment. Now *à priori* one would expect, and from experience of many such cases I can testify that to many women such a prospect is abhorrent. They do not want to be constantly reminded of the existence of their internal organs; the periodic examinations are distasteful to them; the constant douching necessary to keep a pessary clean is nothing short of a nuisance, and they accept with surprising alacrity the suggestion that they may undergo an operation to rid them of this great incubus in their life. In this class we find married women of some years' standing, young married women, to whom a pessary appears as a barrier between them and their husbands, and their hopes of happy maternity, and single women, to whom every examination is a veritable ordeal.

I maintain that in the past the requirements of these patients have not been adequately met; they have had to put up with an objectionable treatment, or "grin and bear" their pains and discomforts unrelieved. If we can open to them a door of relief and bar it in their face, we fail in our duty. There is a perfectly fair parallel in the case of hernia in men. If a man with a hernia came to us and said that he did not wish to wear a truss, but preferred to undergo a radical cure, even though he realised the slight risk attendant on this procedure, we should without hesitation put him in the way of obtaining his wish. The wearing of a truss by a man is a far slighter hardship than the wearing of a pessary by a woman. The only valid argument against operative treatment of displacements as a matter of election would be one that could demonstrate that the operative risk was excessive, or that the results were bad. The risk in these days is very slight. I have published my results fully from time to time. In my first 10 years I had three deaths in 64 cases, all from broncho-pneumonia. In the last 10 years I have had three deaths in 509 cases, one from diabetic coma, one from oral sepsis, and one from pneumonia. I submit that these figures would compare not unfavourably with any series of 500 cases of radical cure of hernia. As regards the later results of operation, I have reported from time to time the after histories of my own cases. The latest report was in the discussion at the Royal Society of Medicine, in March of this year, when the total number of cases traced amounted to 373, a larger number than those reported so far in the practice of any other operator. The figures are large enough to make the deductions from them trustworthy; they showed: (1) that in 90 per cent. of cases the general condition of the patient was much better than before operation; (2) that in 96 per cent. of all the cases, and in 98 per cent. of the later ones, the displacement was permanently cured; (3) that 62 confinements had followed the operation; with two more natural confinements that I have recently heard of, the number is now 64, in none of which has there been any complication that could be attributed to the operation; (4) that the uterus had maintained its good position, in spite of pregnancy and labour, in 97 per cent. of cases; (5) that the patients had been free of bladder disturbance, or had no more than before operation in 85 per cent. of cases, 20 per cent. having actually improved.

From the facts given it is clear that any argument against the operative treatment of displacements, based on the assumption that the operative mortality was high, or the after-results bad, would fall to the ground.

One speaker, in the discussion referred to, expressed the opinion that these operations were being done much too frequently. Such a position is as unsound as religious intolerance. The cure of a patient is the one aim of medicine and surgery; and if one man finds that he gets the best results from one method, and another finds that he is most successful using another method, neither has the right to say of the other that he is not justified in using his method, or to impose any limitations as to how often he may use it.

The correct attitude is to keep an open mind; to adopt such methods as appear to be giving the best results; and to abandon those methods whose results are inferior. Success in treatment is the final arbiter in all therapeutic measures; and I am convinced by experience that in the treatment of uterine displacements they will meet with the greatest success who recognise that pessaries, while they have their place, have also their limitations; and are prepared to avail themselves of the resources of surgery in suitable cases.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Dr. Froelich, Professor Agrege in the Faculty of Medicine, Nancy. Subject: "Is it Necessary to Operate in Spina Bifida?"*

ORIGINAL PAPERS.

THE MEDICAL TREATMENT OF PEPTIC ULCER. (*a*)

BY THOMAS R. BRADSHAW, M.D.DUB., F.R.C.P.LOND.,
Senior Physician to the Liverpool Royal Infirmary.

THE class of case to which the following remarks apply is one which is familiar to every practitioner. The patients are mostly women; their age is generally somewhere between puberty and menopause; they come to us with symptoms which are almost monotonous in their uniformity. They all tell us that the taking of food is followed by severe pain; they mostly tell us that the pain ends in vomiting; the majority tell us that at some time during their illness the vomit has contained blood. On examination we find some evidence of impaired nutrition, though a marked degree of emaciation is rare; there is a moderate degree of anæmia, and if there has been much loss of blood it may be very pronounced. Examination of the abdomen with eye and hand reveals nothing abnormal, except perhaps some hyperæsthesia in the epigastrium; with the fear of exciting hæmorrhage before our eyes, we dare not attempt to elicit further information by the use of the stomach tube or the bismuth meal. The materials for making a diagnosis are scanty; the need for a provisional diagnosis—a working hypothesis at least—is urgent. The question presses—Is there or is there not ulceration of the stomach or duodenum, that is, of the regions exposed to the action of the acid gastric juice? Now before we can frame an answer we must be agreed as to what we mean by an ulcer. The old definition of ulcer, "Breach of continuity with loss of substance," will serve us well enough. Now, given a free discharge of blood from the surface of a mucous membrane, who will venture to deny the existence of a breach of continuity in that membrane? Apart from clean incised wounds which we have not to consider here, I fail to see how such a breach of continuity can arise in a mucous membrane without the destruction of some, at least, of the superficial structures of that membrane. The occurrence of hæmorrhagic erosions has been invoked to explain hæmatemesis apart from ulceration; but a hæmorrhagic erosion is neither more nor less than a breach of continuity with a small loss of substance, and Sir William Osler with his usual precision and conciseness lays it down that there is no difference between hæmorrhagic erosion and the acute form of gastric ulcer. I submit, therefore, that in all cases in which there is or has been gross bleeding into the stomach or duodenum are or have been suffering from ulceration of one of these organs, or to use the most convenient and comprehensive term, that they are or have been the subjects of peptic ulcer.

But the absence of obvious signs of hæmorrhage in the vomit and the stools by no means excludes the possibility of ulcer. The presence of pain and vomiting of a certain kind in a patient with a history of antecedent hæmorrhage points to the possibility of existing ulceration; pain and vomiting even where no history of hæmorrhage can be obtained may by themselves be so strongly suggestive of the presence of peptic ulcer, as to call for the exercise of the same precautions and the employment of the same treatment as we should adopt if the presence of ulceration were proved to demonstration.

The treatment I have employed during the past three years in cases of peptic ulcer of the kind I have described has been on the lines laid down by the late Professor Lenhartz of Eppendorf, Hamburg. The first essential of this, as of all rational methods of treating peptic ulcer, is, I need hardly remind my hearers, rest of mind and body, as nearly absolute as can be obtained. The distinctive feature of the Lenhartz method of treatment is that the preliminary period of complete abstinence from food, tempered it may be by the so-called rectal alimentation, is dispensed with, and as soon as the patient comes under observation, the administration of small quantities of highly albuminous food at frequent intervals is begun.

My method of carrying out this line of treatment is extremely simple and is as follows:

The patient is put to bed, is not allowed to sit up or make any exertion, and must be fed by the nurse. As soon as possible the administration of raw eggs mixed with milk is begun. The exact quantity may be varied somewhat according to the special features of the case, but my usual practice is to order a pint of milk and one egg to be taken during the first twenty-four hours, two ounces of the mixture being given every two hours, and two feeds being omitted during the night. Next day the quantity of milk is increased to a pint and a half, and on the third day a second egg is added. The amount of nourishment is rapidly increased daily by the alternate addition to the diet of one egg and half a pint of milk, until the patient is taking three eggs and three pints of milk daily,

---

(*a*) Paper read at the Section of Medicine International Congress of Medicine, London, August, 1913.

always in divided portions every two hours. This full amount is usually maintained for three or four days, and then fish is ordered and a gradual return is made to ordinary food. In a few cases in which hæmorrhage had been very recent and abundant, or the patient's condition seemed to be more than usually grave, I have ordered one-half the usual quantity of nourishment to be given during the first twenty-four hours, and have increased the amount more gradually. I have thought that a wise precaution to adopt, though I am by no means sure that it is necessary. As a rule no medicine is required.

During the last three years I have carried out this treatment in the case of thirty patients in my women's ward, patients who presented symptoms pointing to peptic ulcer. In fifteen of these there had been hæmatemesis, often profuse, within a week of the patient's admission to hospital. In eight in which there had been no recent hæmorrhage, there was a history of hæmatemesis or melæna at some time more or less remote; in only seven of the cases was there no record of hæmorrhage at any time. As a rule, almost without exception, as soon as the patients were put to bed, and fed in the way I have described, the pain and sickness subsided. There was never any accident, all the cases made a complete and uninterrupted recovery; the average time they spent in hospital was 23.2 days, the longest being 40 days and the shortest 9 days. The last patient had had melæna, and had fainted, 10 days before admission. She left the hospital, apparently well, at her own request, the day after she was put on low diet with fish. Of the 15 cases which had had hæmorrhage within a week of admission the average stay in hospital was practically the same as that of the whole series, namely, 24 days, the longest being 33 days and the shortest 14.

With few exceptions the patients showed no dislike to the diet, the pain ceased after one or two days, the vomiting did not return. In only one case was there a recurrence of hæmatemesis after the milk and egg regimen had been established. The patient, a few days after her admission to hospital, was allowed to see her husband who was going to sea. He arrived at the ward in a state of intoxication, the patient was much agitated by the visit paid under such circumstances, and soon afterwards vomited blood. She ultimately made a good recovery, and left the hospital after forty-one days. I have not, however, included her case in my statistics, because owing to the distressing circumstances I have mentioned, the essential condition of mental and bodily repose was at first not maintained.

The treatment I employ differs in some minor details from that laid down by Professor Lenhartz, and differs chiefly in the direction of simplicity. Thus I do not have the food iced, nor do I apply an ice bag to the epigastrium. I seldom order uncooked meat in the course of the treatment, and I do not prescribe bismuth unless the pain persists, which is rarely the case. I have had but few cases in my men's ward conforming to the type of peptic ulcer which I have described. In my experience, peptic ulcer in men as met with in the wards of a hospital is generally of a chronic type, and when it comes under observation has already produced such deformity as to call for surgical interference. Still I have had a few cases in which the treatment I have described has appeared to me to be indicated and the results have been highly satisfactory. It will probably be objected that many of the cases which I have described were not the subject of gastric ulcer at all. As I have already suggested, we are probably not all in agreement as to the meaning of the term ulcer in this connexion, but I think that whatever our definition of ulcer may be, we shall all admit that the majority of my cases were suffering from that condition.

I need hardly point out that the mode of treatment I have described cannot be expected to lead to recovery in old cases that have gone on to the production of stenosis or other structural changes in the stomach. Such cases are pre-eminently suitable for surgical interference, and their successful treatment by operation is amongst the most brilliant of the triumphs of modern surgery. There are, however, not a few cases where the physician is in doubt as to whether the ulcer has gone on to the production of cicatricial changes or not, and in them the egg and milk treatment can be used with much advantage until the diagnosis is fully established.

I submit that this treatment compares very favourably with the other forms of medical treatment in vogue. It does not tend to increase the anæmia and exhaustion already present, it is free from the discomfort and distress incident to the withholding of food and the administration of nutrient enemata, it has no special drawbacks of its own, and does not favour the occurrence of hæmorrhage or perforation, it is not costly, it leads to early relief of pain, and is followed by rapid restoration to health.

LICHEN PLANUS. (*a*)

By DAVID WALSH, M.D.Edin.,
Senior Physician, Western Skin Hospital, London, W.

Amongst diseases of the skin lichen ruber planus—to use its fuller title—is certainly not the least interesting and important. Its history affords a good illustration of the general advance of dermatology, while at the same time it reminds us somewhat sharply of the limitations of knowledge with regard to the causation and various other essential facts connected with so well recognised a condition. The study of *lichen planus*, indeed, is stimulating to dermatologists not only because of what we have already learnt, but even more so because of what is not yet known. The disease occurs often enough to enable most private practitioners and all dermatologists to become familiar with its features. The following brief systematic outline of the malady will serve to suggest a few of the points to which discussion may be specially directed.

Definition.—Lichen ruber planus is an inflammatory condition of the skin of obscure origin, usually chronic, characterised by small, firm, dry, reddish or lilac, itching, flat-topped, angular or polygonal, non-scaling papules, involving all layers of the skin (sometimes mucous membranes), and leaving more or less prolonged pigmentation after recovery, which takes place as a rule in a few months or years without serious impairment of health.

History.—Lichen planus was formerly regarded as a form of dry, papular eczema, and it was only in 1869 that Erasmus Wilson described it as a separate condition, under the name of lichen planus. About the same time it appears to have been identified by Hebra as lichen ruber. The name usually adopted by dermatologists nowadays is that given to the condition by Wilson. It is not one of the common affections of the skin: according to Crocker (*b*) it forms in dermatological practice 1 per cent. of hospital and 2 per cent. of private cases. The fact of its comparatively recent differentiation is somewhat curious, for in the majority of instances it presents sharply marked characters. Its rarer varieties may now and then elude the vigilance of even skilled dermato-

(*a*) Paper to open discussion read (in abstract) before the New London Dermatological Society at the Western Skin Hospital, October 9th, 1913.

(*b*) Radcliffe Crocker, "Diseases of the Skin," vol. i., p. 379.

logists, while in its ordinary, well-marked, chronic form it gives rise to constant errors of diagnosis in private practice.

L. planus may be acute or chronic. The great majority of cases are chronic.

The chronic form usually comes on insidiously and appears in crops of papules, which may last for months or years. It may remain as discrete papules, or these may run together into patches, near which typical papules are invariably to be found. The tendency to run into patches is most marked in the knees and legs, or round the body where there is pressure. The patches show a lilac colour and are often imperfectly scaled.

The essential feature of lichen planus is the flat, firm, angular papule, which retains its form throughout the attack, does not weep nor become pustular, and does not extend at the circumference. As a rule it itches, and in some cases may give rise to aggravated discomfort. Its colour is usually pale or dull red to purple; this colour cannot be all squeezed out by pressure. Its size is from a pin-point to that of a hemp seed. Its shape is angular, corresponding to the natural lines of the skin. It rises abruptly from the skin and has a flattened top, which is sometime umbilicated, due probably to the centre being tethered, as it were, by a sweat duct. Its colour may be pale pink, but is more usually red or lilac. It has a peculiar translucent or waxy, glistening or shiny look, which can be best seen by looking at the eruption slantwise. The shiny appearance is due to the stretching of the thickened, horny layer of the epidermis by the underlying papule. Sometimes the papule heals in the centre and becomes annular, or papules may run end to end in a circular or horseshoe or linear form. To the touch the papules are firm and rough.

A remarkable point is the pigmentation left after the clearing up of the papules. This may be of any shade of brown, from a faint staining to a deep, blackish hue, which in marked cases persists for months or years. At times the macule is faintly cicatricial.

Itching varies: it is not always present, although in the majority of cases it presents a marked symptom. It may be slight, or it may be so severe as to prevent sleep, and even seriously affect the health of the patient.

The patches are formed by the running together of individual papules. In the legs they are often covered with scanty scales, and there is a good deal of hypertrophy, so that the condition somewhat resembles psoriasis—indeed, the late Sir Jonathan Hutchinson long ago called the condition lichen psoriasis.

[Several sketches of lichen patches resembling psoriasis on the legs were shown. In each case there was a history of traumatic origin in patients suffering from heart disease, in which a patchy, chronic lichen planus eruption developed and generalised.]

The distribution of the disease is interesting. It affects by choice the fronts of the wrists, the inner sides of the thighs, and the lower parts of the legs, also the back of the neck. It often occurs on the trunk, and may affect every part of the body, rarely the scalp, palms and soles, and in extremely rare instances the face. The papules may be arranged in lines, and may follow the course of a nerve. An interesting point is that of traumatism. The papules sometimes appear along the lines of scratching, or they may be caused by pressure, such as that of a garter or of the clothes around the waist. This latter observation suggests that the surface circulation may be concerned in the determination of the rash, and that parts where there is local circulatory or lymph stasis due to pressure may be predisposed to the lodgment of some specific pathogenic micro-organism. In this connection a patient is shown here to-day. Her age is 65, and she has chronic lichen planus with pretty general distribution of discrete, shiny, red itching papules, the size of hempseeds, of a month's duration. She has advanced valvular disease, and is one of several cases where lichen planus has been found associated with cardiac disease.

Case of Lichen Planus.—C.F., æt. 65, cook, came first to hospital complaining of an irritating rash on arms and legs, which began on the lower limbs six months previously. As a girl, she had scarlet fever and "brain fever." For the last 25 years she has suffered from "colds" and bronchitis. She has palpitation, shortness of breath, and dyspepsia. Her feet swell and she has habitual constipation. The pulse is 100, compressible, and regular. There is an aortic direct murmur, conducted into sub-clavian and carotids. The apex is felt in fifth and sixth interspaces. Cardiac dulness extends half an inch outside the left mid-clavicular line. The eruption is that of a typical lichen planus. On the arms it shows as numerous discrete, shiny, firm, red papules.

Lichen planus is usually symmetrical. It often attacks the mucous membranes, and is seen on the tongue and inner lining of the cheeks, but rarely in the fauces, in the form of whitish lines or patches. It is supposed to affect the rest of the alimentary canal in a similar way, and to account for the dyspepsia and diarrhœa that sometimes accompany the malady.

Acute Lichen Planus.—Sometimes the disease develops acutely. The papules are like those of the chronic form, but cover a greater surface, and there is more scaling and more intense itching. Every part of the body except the face may be involved. A good deal of pigmentation follows the disappearance of the eruption, and recovery as a rule is comparatively rapid, although some attacks lapse into the chronic form of the disease. Sometimes the patches of chronic lichen planus develop a warty growth. There is usually considerable thickening of the skin, and painful cracks and fissures occur. As in various other skin affections the warty element may be regarded as a sort of pathological accident. In extremely rare cases vesicles or bullæ may develop on the lichen planus papules as patches. Other infrequent variations have been described.

Ætiology.—Lichen planus attacks adults of both sexes and occurs among all classes of society Little is known as to its predisposing and determining conditions. The disease appears, as a rule, in patients of apparently good health, although in many instances a history of nervous troubles is present. From the consistency of the eruption and its well-defined features one is inclined to believe that lichen planus is possibly due to a specific micro-organism. From the fact that in its typical form it presents a chronic inflammatory condition of a granulomatous type, an analogy has been traced with the gummata of syphilis, and it has been suggested that a spirochæte may be the cause of the mischief.

The neurotic element is undoubtedly present in many cases of lichen planus, as evidenced by history of shock, tremors, headaches, and other signs of nervous instability.

Pathology.—Microscopically, the characters are constant. Both superficial and deep layers of the skin are involved, and the process is generally believed to begin in the papillary layer of the corium. There is overgrowth of the principal layer, and, according to some observers, especially of the stratum granulosum, with thickening of the horny layers. The papillæ are elongated, and with the underlying corium, are packed with a dense cellular inflammation. The healing centre in annular lichen planus resembles the similar process in some syphilitic and tubercular eruptions.

Diagnosis.—The diagnosis in well-marked cases is easy so long as the character and grouping of the planus papules are borne in mind. Chronic, scaly, planus patches on the legs are often mistaken for psoriasis: they may be distinguished by their imperfect scaling, their itchiness, their bluish look, the invariable occurrence of satellite planus papules, their non-appearance on the elbows and knees, and, in my own opinion, by the common association of some grave circulatory defect.

Perhaps the commonest mistake in diagnosis is the confusion of lichen planus with papular eczema. The latter disease is multiform and catarrhal, and a careful examination would show that the rash was not uniformly papular. Lichen planus is sometimes mistaken for an early secondary papular syphilide: the syphilitic rash does not irritate, it is multiform, and there are other evidences of the disease: there is a patchy tertiary rash rather like lichen planus, but it usually shows more or less scarring, which lichen planus does not. At times the planus papules, especially if few in number, escape notice, and the patient is treated for the pruritus, which may be general and severe.

Prognosis.—Some cases recover after a few weeks or months, but the chronic case may persist for years, especially the patchy form on the legs. The general health is rarely seriously affected. Sometimes the itching may prevent sleep and so injure the health, or there may be gastric symptoms and diarrhœa.

Treatment.—Itching is one of the most troublesome symptoms. Antipruritic remedies, such as sponging with a lotion of carbolic acid and spirits of camphor, is useful; rest in bed and opiates may be necessary. Individual patches may be painted over with salicylic collodion. Of all internal remedies, arsenic receives the most general support. Good results are often obtainable from the liquor hydrargyri perchloridi. Personally, I never use arsenic, but begin at once with the liquor, which appears to exert a more or less specific effect upon the disease. X-ray treatment is sometimes useful, and the patches often disappear under some form of electrical current. Recently lumbar puncture has been advocated by Raval, of Paris. In our own country, Pernet has reported a case of lichen planus in which severe pruritus disappeared a few hours after its application, but the treatment seems rather heroic for what is, after all, a purely subjective symptom that can as a rule be alleviated by milder measures.

Local Treatment plays a minor, but still an important part in dealing with this complaint. Unna uses the following formula:—

Ac. carbol. pur., gr. xx.
Hydrarg. perchlor., gr. i. or iii.
Ungt. zinci benzoat., oz. i.
M. ft. ungt.

It is sometimes useful to apply carbolic acid or other drugs in collodion, which is painted over the patches. Tar is a good remedy and may be used in the form of liquor carbonis detergens; resorcin, or as liquor picis carbonis, painted over the papules. Cyllin, salicylic acid, and, generally speaking, remedies used for psoriasis, are available for lichen planus.

POLIO-ENCEPHALITIS AND POLIO-MYLETIS. (*a*)

By FREDERICK E. BATTEN, M.D.Cantab., F.R.C.P.Lond.

Physician to the Hospital for Sick Children, London, and Physician to the National Hospital for Paralysis and Epilepsy.

Since the International Congress of Medicine met in Budapest in 1909, great advance has been made with regard to our knowledge of polio-myelitis and polio-encephalitis. It is true that in December, 1908, Landsteiner and Popper had succeeded in communicating polio-myelitis from human being to monkey; but all the knowledge which we now possess with regard to the nature of the virus has been furnished by the experimental work of Landsteiner and Levaditi, Flexner and Lewis, Leiner and Wiesner, Roemer and Joseph, and many others during the past four years, and I feel sure that I express the feeling of this section in saying how greatly we regret that Professor Flexner and Professor Roemer have been prevented from opening the discussion on this subject, as was announced in the earlier programmes of the transactions of this Section.

It was only in May of this year that I was asked to perform the task of opening this discussion, and I feel greatly the honour which this Section has done me, and trust that they will forgive many shortcomings which might have been avoided had longer time been given me for preparation.

I take it that it is the duty of the reporter to place before the section a *résumé* of the recent work which has been done on the subject under discussion, and to bring into prominence those points on which some difference of opinion exists. This I shall endeavour to do; but the subject of polio-myelitis and encephalitis is so vast that the consideration of any one part might occupy the whole of the time at my disposal. I propose, therefore, to deal with (1) the experimental work; (2) the clinical types of the disease; and (3) the disease as it affects England and this metropolis.

Experimental Work.

In 1908 Landsteiner and Popper succeeded, by means of an injection into a monkey of the substance of the spinal cord taken from a case of acute polio-myelitis, in producing a disease which both clinically and pathologically was quite analogous to that occurring in human beings. They did not succeed in transmitting the disease to a series of monkeys.

In 1909 Knöpfelmacker produced the disease in a monkey by injecting into the peritoneum an emulsion of the spinal cord from a case of polio-myelitis, and in the same year Strauss and Hontoon, in America, also produced polio-myelitis in a monkey by intraperitoneal injection.

Towards the end of 1909 there came the communications almost simultaneously of Flexner and Lewis, Landsteiner and Levaditi, Leiner and Wiesner, and Roemer, showing that the infection could be transferred from one monkey to another by means of an emulsion of the spinal cord. Then followed a series of experiments as to the nature of the virus.

It was shown by Landsteiner and Levaditi and by Flexner and Lewis that the virus of polio-myelitis was a *filterable virus*, and would pass the Berkefeld, Chamberlain, Reichel, and Pukall filters: but that after such a passage through the filter the virus lost some of its virulence, and the incubation period was always prolonged.

It was also shown by these observers that the virus may be *preserved* for many months in pure glycerine or 50 per cent. of glycerine in water, without affecting its virulence. In this respect the virus resembles that of rabies and vaccinia. The organism will withstand prolonged *drying*, so that material dried at 22° C. for twenty-four days was still virulent.

The cultivation of the organism has up to the present not been definitely accomplished. Small round and oval corpuscles have been described under the ultramicroscope, and quite recently Flexner and Noguchi have described a medium and method of growth under anaerobic conditions. They describe minute colonies of globular bodies averaging .15—.3 of a micron in size. These bodies stain a pale reddish violet in Giemsa solution. Monkeys inoculated with the cultures have developed typical polio-myelitis, but the authors are evidently fully aware of the possibility of the carrying over of a quantity of the original virus sufficient to cause paralysis in the inoculated monkeys, and further experiments are in progress to prevent such an occurrence.

Experimentally it was found that the most certain *method of infecting monkeys* was by injecting .5 c.c. of an emulsion of an infected spinal cord into the brain, and at the same time injecting 4—5 c.c. into the peritoneal cavity. Subcutaneous and intravenous injections are, however, frequently successful in producing the disease. The virus will pass the uninjured nasal mucous membrane, and will also penetrate the intestinal mucous membrane, as has been shown by Leiner and Wiesner. The earlier experiments failed to demonstrate the presence of the virus in the saliva and secretions of the mouth and nose, although Flexner and Lewis have shown that the virus was present in the mucous membrane of the nose. The transmission of the disease by means of the blood was also difficult, and Flexner and Lewis only succeeded by using large quantities (25 c.c.) taken from the monkey at the height of the disease. Leiner and Wiesner only succeeded in one case out of six attempts in producing infection by means of the blood. Shortly it may be said that the virus exists in the central nervous system, in the mucous membranes of the nose, in the tissue of pharynx, in the lymphatic glands, rarely in the salivary glands, and still more rarely in the blood; but it could not be proved to be present in

---

(*a*) Read before the Section of Diseases of Children, International Congress of Medicine, London, August, 1913.

the buccal, pharyngeal, nasal *secretions*, or in the fæces.

The great epidemic of polio-myelitis in Sweden, in 1911, gave the observers Kling, Pettersson, and Wernstedt the opportunity of a thorough investigation. They obtained washings from the mouth, nose, pharynx, upper air passage, and small intestine of a number of patients: (1) dead of the disease; (2) living cases; (3) abortive cases; (4) healthy persons in contact with infected individuals. Washings from these mucous membranes obtained (1) *after death* were filtered through a Heims filter, and by a combined intraperitoneal injection with an inoculation into one sciatic nerve of the filtrate they succeeded in infecting monkeys. Out of fourteen patients dead of polio-myelitis, thus investigated, in only one were the authors unsuccessful in demonstrating the presence of the virus of polio-myelitis. It is, however, interesting to note that the changes in the spinal cord, which have been considered most characteristic of polio-myelitis, *i.e.* cellular infiltrations, were not always present. In fact out of 59 monkeys, which were infected from typical cases of polio-myelitis, 25 (*i.e.* 42 per cent.) showed infiltrative changes, and 34 (*i.e.* 58 per cent.) degenerative changes.

The degenerative changes have been noted in the cells of the supporting tissue, and also in the ganglion cells into which the large clear surrounding glia cells have eaten their way. These observers consider these changes to be due to, and characteristic of, the effect of the virus of polio-myelitis. The proof that these are cases of polio-myelitis lies in the fact that control experiments made with the spinal cord have produced quite typical perivascular infiltrations and leucocytic neuronophagia.

2. *Living Cases of Polio-Myelitis.*—Having obtained results from persons dead of polio-myelitis, the authors next proceeded to investigate the secretions from living persons, and they obtained material from the mouth, nose, pharynx, and large intestine of twelve living persons suffering with polio-myelitis. In only one case did the observers fail to infect the monkeys. Thus the presence of the microbe has been detected in the secretions of one of the examined membranes, *i.e.* mouth, nose, upper air passage or intestine, in 24 cases out of 26 cases. Considering the difficulty in infecting monkeys in every instance, the observers consider themselves fully justified in drawing the following conclusion, viz. that the virus in all probability is always present in the mucous membranes of the nose, mouth, pharynx, and intestine of persons affected by polio-myelitis during the acute stage of the disease.

3. *Abortive Cases, and* 4. *Healthy Persons in Contact with Infected Individuals.*—Having obtained results from persons suffering with definite polio-myelitis, the authors proceeded to investigate the washings from the mucous membranes of abortive cases and healthy persons. In a family of five, one of whom had definite polio-myelitis, two an uncertain illness of short duration, and two had remained well, they showed that three carried the microbe of polio-myelitis in their mucous membranes, viz. the one who had distinct paresis, one of those who had an abortive attack, and one of those who had had no illness.

The existence of the micro-organism of polio-myelitis has been demonstrated also in the secretion from the mouths of three persons, who had not, as far as is known, had any contact with patients showing definite paresis, persons whose illness was characterised by such vague symptoms that only in one case did the suspicion arise that some form of polio-myelitis was present. The virus of polio-myelitis has been demonstrated in perfectly healthy individuals living in the neighbourhood of cases of polio-myelitis. Out of a family of five, one of whom had polio-myelitis, three were shown to be virus carriers. In six families the experimental method has demonstrated the existence of carriers of the virus in several members of the family, only one person in each family having typical paralysis. It is therefore probable that virus-carriers are very common.

HOW LONG MAY THE VIRUS REMAIN IN THE MUCOUS MEMBRANES.

Osgood and Lucas found it still present six months after an attack. The Swedish observers state that virulent organisms were present in the buccal secretion seven months after the onset of the disease.

That the virus with which these observers were dealing was that of polio-myelitis is proved by a variety of experiments.

The observers also took washings from the mucous membranes of five healthy individuals, and injected them into monkeys. No infection took place.

EXPERIMENTAL INVESTIGATIONS WITH THE OBJECT OF DETERMINING THE POSSIBILITY OF TRANSMISSION OF POLIO-MYELITIS BY MEANS OF DEAD OBJECTS AND FLIES.

Flexner and Lewis, Landsteiner and Levaditi and Roemer found that prolonged drying even for twenty-four days at a temperature of 22° C. did not diminish the virulence of the virus. Leiner and Wiesner, however, found that drying of the film for four hours at a temperature of 37° C. did destroy the virus. Landsteiner, Levaditi, and Pastia found that the virus remained potent in sterile milk and sterile water for at least thirty-one days. Josefson succeeded in producing experimental polio-myelitis with a handkerchief and fancy work. Neustaedter and Thro succeeded, after may failures, in producing polio-myelitis in a monkey with a filtrate of macerated dust collected from rooms in which cases of polio-myelitis had been nursed. Howard and Clark showed that the domestic fly can carry the virus of polio-myelitis in an active state for several days upon the surface of the body, and for several hours within the gastro-intestinal tract, and that the bed bug has taken the virus with the blood from infected monkeys and maintained it in a living state within the body for a period of seven days. Rosenau in 1912 demonstrated that polio-myelitis could be transmitted from monkey to monkey by the means of the bite of the stable fly (*Stomoxys calcitrans*), and this observation has been confirmed by Anderson and Frost. These experiments are the more remarkable for it is a matter of some difficulty to infect a monkey with the blood of a patient suffering from polio-myelitis, and as a rule a considerable quantity is required. Kling, Petterson, and Wernstedt failed to communicate the disease by the means of fleas.

THE CLINICAL PICTURE OF EXPERIMENTAL POLIO-MYELITIS IN MONKEYS.

The clinical picture of experimental polio-myelitis in monkeys as described by Landsteiner and Levaditi, Flexner, Lewis and others is similar to that which occurs in man. In addition to the ordinary type of limb paralysis, the muscles of the face, the oculomotor muscles are paralysed, sometimes alone, sometimes in association with limb paralysis, and Roemer has reproduced the "jump" type in monkeys, which is a rare manifestation in man. In view, however, of the pathological finding of Kling, Petterson, and Wernstedt, who stated that a considerable number of their cases show degenerative changes, it is important to study the clinical picture in their cases. That the clinical picture of experimental polio-myelitis may in animals other than the monkey vary greatly is shown by Marks in his experiments on rabbits, and Leiner and v. Wiesner have described a type of slowly progressive weakness in monkeys which they have designated as "marasmic."

Kling, Petterson and Wernstedt have divided the 116 monkeys who suffered from polio-myelitis into six clinical groups: (1) an upper, (2) lower, (3) mixed, (4) cerebral and bulbar type, (5) general muscular weakness, (6) "found dead." The first four groups are so well known and correspond to the usual type in man that no comment is necessary. With regard to the general muscular weakness which the authors use as synonymous with the "marasmic type" of Leiner and v. Wiesner, it has no known counterpart as a clinical type in man.

The feature of this "general muscular weakness" group is weakness without localised paresis, and the authors state that they have found the disease manifesting itself in this manner in no less than 26 out of the 116 cases.

A monkey (No. 140) inoculated on November 1st was noticed on November 16th to be more slow in its movements. By November 20th it moved somewhat joltingly, but otherwise well, possibly weak in the fore limbs. November 25th: Has during the past days been huddled up in one spot, and to-day is lying at the bottom of the cage and moves very little. It died on this evening. Microscopical examination showed marked hyperæmia and hæmorrhages, but no cellular infiltration. Some of the glia-cells distinctly enlarged. The ganglion-cells generally dark and rather homogeneous, some of them being besides shrunken and vacuolated, enlarged glia-cells often having eaten their way into them, the changes, however, on the whole, not very pronounced. The clinical picture differs considerably from that which is usually accepted as that of polio-myelitis, as do also the pathological findings. The question might well be asked: Is this disease polio-myelitis? The experimental proof on this point is complete; for the animal was infected from another animal which gave the typical clinical and pathological picture.

The Histological Changes in the Spinal Cords of Monkeys Affected by Polio-myelitis.

Kling, Petterson, and Wernstedt describe two distinct pathological conditions in the monkeys dead of polio-myelitis.

(1) The infiltrative type, the pathological picture commonly presented by the spinal cord of monkeys in connection with experimental polio-myelitis.

(2) The degenerative type, in which cellular infiltration is absent and the striking change is degeneration of the nerve-cells. This degeneration affects not only the nerve-cells, but also the cells of the glia. The authors describe in fact two degenerative types. The one in which the ganglion-cells are encroached upon by a large number of cells which are polymorphonuclear leucocytes and poly-blasts, the poly-blasts being, according to Wickman, the real neuronophages. The second, in which a cell having a large clear rounded cell-body, eats its way into the ganglion-cell. This the authors designate as "glia-cell neuronophagia."

An important point is the proportion between the cases in which infiltrative and degenerative changes have been observed in experimental animals. These figures show that animals inoculated from virulent cases give a far greater percentage of infiltrative cases than those inoculated from abortive and convalescent cases.

	Animals dead.	Infiltrative.	Degenerative.
(1) Typical cases	59	25 (42 p.c.)	24 (58 p.c.)
(2) Abortive and virus carrier	34	1 (3 p.c.)	33 (97 p.c.)
(3) Convalescents	23	2 (8 p.c.)	21 (91 p.c.)

The greater virulence and the appearance of the inflammatory infiltration evidently go hand in hand in the monkey. The authors come to the conclusion that the degeneration of the ganglion-cells as well as the cellular and humoral exudation are to be regarded as the result of a direct injurious influence of the virus.

This is a new light in which to regard the action of the virus of polio-myelitis, for in the past the changes in the nerve elements have been regarded as secondary to the infiltration of the tissues. Further experiments are necessary to confirm or disprove the view expressed by these authors. This question will be further discussed from the clinical aspect.

The Swedish epidemic of 1911 greatly exceeded the epidemic of 1905. In the month of September, 1911, more cases occurred (viz., 1,067) than in the whole of 1905, the total number for 1905 being 1,016; for the year 1911 being 3,840. From topographical studies, the investigators conclude that the epidemic of 1905 produced a general and widespread immunity to polio-myelitis, for the areas which were affected in 1905 practically escaped in 1911.

Clinical Manifestations of Polio-myelitis and Polio-encephalitis in Man.

Everyone will now recognise that the virus of polio-myelitis may affect any portion of the nervous system, and may thus give rise to a variety of clinical pictures. These have been described by Wickman under the following types:—(1) The spinal type, (2) the ascending and descending, so-called Landry type, (3) the bulbar and pontine type, (4) the encephalitic type, (5) the ataxic type, (6) the neuritic type, (7) the meningeal type, and (8) the abortive type. Peabody, Draper and Dochez, in their excellent investigations on the clinical features of polio-myelitis, criticise this classification, saying that it is based neither on pathological anatomy nor on clinical symptomatology, but on a mixture of the two. They prefer the classification suggested by Müller on anatomical basis—viz., (1) the spinal form, (2) the bulbar form, (3) the cerebral form, (4) abortive cases; but even here one has to introduce a clinical division (abortive cases) with the anatomical. I do not propose to discuss at length the various clinical manifestations to which an infection by polio-myelitis virus may give rise, but there are certain types of the disease which are not commonly recognised, and it is to these that I should call special attention.

The cerebral type, to which Strümpell first called attention in 1885, giving rise to hemiplegia, is to a certain extent called into question by Peabody, Draper and Dochez, and they point out that Wickman, who, in the Swedish epidemic in 1905 had the opportunity of seeing many cases, did not see any definite cerebral case of this nature. They record an instance of sudden onset of left hemiplegia in a child which suggested the diagnosis polio-encephalitis, and in whom the blood serum, mixed with the acute specific virus, failed to prevent the infection of a monkey, and therefore the case was probably not one of infection by acute polio-myelitis.

Several instances of hemiplegia in one member of a family in whom other members are affected with typical polio-myelitis have been recorded, and hemiplegia in association with typical polio-myelitis in the limbs is on record; but it must be admitted that the pathological evidence on this type of the disease is not complete.

The acute ascending type of polio-myelitis is more generaly recognised, but the "jump" type, in which the disease remains stationary for several days and then rather suddenly and rapidly advances is by no means so generally recognised.

The bulbar type not infrequently escapes recognition. In this form the stress of the disease falls upon the bulb and gives rise to inability to swallow, to paralysis of the palate and tongue, to cardiac irregularity and great dyspnœa owing to the failure of the diaphragm and respiratory muscles. The mouth becomes filled with frothy saliva, which the child is unable to swallow. The child is intensely restless, acutely conscious, and irritable. Respiration becomes an active, voluntary process and every breath represents hard work. The clinical picture is one which is so striking that when once seen it is never forgotten, and apart from polio-myelitis is only seen in deaths from myasthenia gravis and probably in rabies, although of this latter condition I cannot speak from personal experience.

The cerebellar type is characterised by acute ataxia either unilateral or bilateral, and such ataxia may be seen in association with a typical flaccid paralysis of a limb or of one side of the face in the same patient, or in another member of the same family. Most observers will, however, accept the above types as manifestations of polio-myelitis, but few will be willing to accept the so-called "neurotic form," and it is this form which I propose to discuss in the light of recent research. If the presence and persistence of pain are taken as evidence of "neuritic type" of the disease, then it may be asserted that there is no justification for the title, since both these symptoms are well recognised accompaniments of affection of the spinal cord. If, however, there is evidence of weakness and wasting of peripheral muscles which affects all the extremities more or less symmetrically, and at the same time there is definite alteration of sensation in the peripheral portion of the limbs, with tenderness of the muscles, then it would be justifiable to regard such a case as one of neuritis. If such a case occurred with a sudden onset, or in association with typical cases of polio-myelitis in other members of the same family or household, it would be justifiable to assume that the same poison was the causative factor.

Wickman discusses this question at some length and quotes the following case:—A child, four years old, is taken suddenly ill on August 12, 1905, with headache, pain in arms and legs. On August 15th the arms and legs are paralysed; pain all over the body. On August 16th, attack of shortness of breath. On August 19th, better; could move the left arm over the head, and the following day improvement maintained. On August 24th, attack of shortness of breath again. Increase of symptoms. Pain in the legs and arms. The sensibility of the lower extremities is markedly affected. The patient feels nothing below the knee, and only strong stimuli on the thighs above the knee. The sensation of the abdomen, thorax, and upper extremities is maintained. The child slowly improved, and on September 6th the sensibility of the lower extremities had returned; but the child was discharged on October 15th with typical paresis of the legs and right shoulder.

This case had certain symptoms which seem to point to an affection of the peripheral nerves, and was associated with the usual symptoms of a polio-myelitis.

Polio-myelitis, as a rule, has an acute stage which subsides after a period of a few days, and recovery gradually takes place. Rarely, however, after a variable period recurrence takes place, the paralysis extends and may prove fatal. Such a type, which has been named the "jump" type, has been observed in experimental animals by Roemer. Such cases must not be confused with cases exhibiting poly-neuritis. As evidence that polio-myelitis may produce toxic poly-neuritis the following cases may be quoted:—

James F., æt. 16, a milk boy. In July, 1910, he had some pain in both legs. On Saturday, July 30th, he was taken acutely ill, and vomited for three days. Had pain in the abdomen and legs. Remained in bed. On Wednesday, August 3rd, he could not stand, and after that the legs gradually got weaker, and after a few weeks he was absolutely unable to move them, and he could not feel below the knees. He was in bed for two and a half months, and after the seventh week in bed his legs began to get better; the arms were never much affected. He came under my care in November, 1910. He had then weakness of the arms, feeble grasp, generalised wasting. The trunk muscles were good. The legs were wasted below the knee; he had double foot-drop, absent knee-jerks, absent ankle-jerks. Electrical changes of the character of R.D. were present in the muscles of arms and legs. Loss of sensation had cleared up when seen in November, 1910. There was no evidence of lead or arsenic. He recovered under treatment and was discharged well in January, 1911.

The case was obviously one of toxic neuritis. The only question was, what was the nature of the toxin? The sudden onset of symptoms during the month of August suggested the virus of polio-myelitis as the cause; the proof could only be furnished by experiments on animals, and that was not done.

A.L., æt. 30, was, early in May, 1913, taken suddenly ill with weakness of the legs, so that she could hardly walk when she attempted to get out of bed in the morning. She had been perfectly well the night before. She had a squint at this time. Since the onset the legs have been steadily getting worse, and when seen some four weeks after the onset there was bilateral foot-drop, tenderness of the muscles, loss of sensation to all forms below the knee, weakness of the hands, and some slight anæsthesia. The knee-jerks were absent. The clinical picture was clearly one of peripheral neuritis. What the toxin was must remain doubtful; but the sudden onset followed by the gradual increase of symptoms suggests the possibility of the virus of polio-myelitis as the cause. Complete recovery took place.

The third case is that of a boy, E.H., æt. 5 in 1898. He was taken ill acutely at the end of August or beginning of September, 1898. He was feverish, and two days later was prostrated and unable to turn in bed. A week later he had begun to improve and could move his arm and leg. He had no affection of bladder or rectum. He had acute pain in the back when taken ill. He was admitted to the Children's Hospital in October, 1898, and the child was then unable to walk or sit up in bed. He had no cranial nerve paralysis; but his voice was nasal in character from some weakness of the palate. He had general weakness in the legs. The knee-jerks were absent. There was no loss of sensation. The muscles on electrical examination showed reaction degeneration. No response to Faradism in arms or legs, and the A.C.C. was greater than K.C.C. He recovered to a considerable extent and went out of the hospital able to walk, but still very weak.

In 1913 he was seen again. He is now 20 years old. He is of very small stature—4 ft. 2 in. He has a marked scoliosis to the right. Both arms and legs are weak and thin, but the loss of power is general and not local, and does not look like a residual polio-myelitis. He has difficulty in rising from the ground, but can do so. He has difficulty in going upstairs.

The case, when seen in 1898, was regarded as one of peripheral neuritis and attributed to "influenza," which the boy was said to have had; but it is suggested that the virus of polio-myelitis may have been the cause of the toxic neuritis, from which he has never made a complete recovery.

I do not think it can at the present time be asserted that toxic poly-neuritis has been proved to be a manifestation of the virus of polio-myelitis, but if one accepts the experimental evidence that the virus does in some cases act as a direct poison to the neurone, and if one admits that the cases above quoted are definite cases of poly-neuritis with an acute onset, then I think there is reasonable ground for considering that poly-neuritis may sometimes be a manifestation of the virus of polio-myelitis. The question would be solved if we had a specific reaction for polio-myelitis, but such has not yet been determined, although numerous observers have worked at the subject. Considerable information might be afforded by a series of experiments on monkeys in which a known quantity of the virus was mixed with the serum of the affected patient and injected into a monkey, the experiment being controlled by an injection of a similar quantity of virus without any serum into another monkey. If the former failed to develop polio-myelitis whilst the latter did develop that disease, it would be justifiable to assume that the patient had at some time had polio-myelitis or was immune to that disease.

Polio-myelitis in London.

There is no doubt that polio-myelitis has been endemic in London for many years. To my knowledge it has occurred with the greatest regularity during the summer months for the last twenty years. It cannot be said to have been epidemic, although there has undoubtedly been a considerable variation in the incidence of the disease in different years. Charts prepared from cases collected during the years 1904, 1909, 1911, 1912, show how cases of that disease were distributed in London in those years. The cases forming the chart for 1904 were collected by myself, those of 1909 by Dr. Leonard Parsons, those of 1911 and 1912 are the officially notified cases of those years, the Local Government Board having, at the request of the London County Council, kindly allowed the disease to be made notifiable in September, 1911.

Polio-myelitis in England.

England has never suffered from a severe epidemic of polio-myelitis. It has always been a sporadic disease, scattered over the whole country. But there is little doubt that the incidence of the disease in 1911 was unusually severe. The year 1912 was remarkable for its wetness, and very few epidemics of polio-myelitis occurred, but some 691 cases were notified during the year. (These figures do not include the London cases.)

Conclusion.

Polio-myelitis and encephalitis must be regarded as an acute specific fever having an incubation period which is variable, but on the average is from eight to twelve days. The virus is carried in the mucous membrane of the mouth, nose and pharynx, not only of those who have had the disease, but also of those who have only been in contact with the infected. The disease may affect any part of the nervous system, but falls with greatest severity on the grey matter of the ventral horns of the spinal cord. The clinical symptoms to which it may give rise are variable and depend upon the incidence of the virus on the nervous system. Evidence of an experimental nature has been quoted showing that the virus of polio-myelitis may act not only by giving rise to infiltration of the tissues and vessel walls with cells of a lymphocytic nature, but also as a direct poison to the neurone. The former is known as the infiltrative type, the latter as the degenerative type of the disease. The form which the affection takes depends to a great extent on the virulence of the infection. The question whether an acute toxic neuritis may be a manifestation of acute polio-myelitis is discussed, and it is held that although at the present time the evidence for the acceptance of such is not complete, yet the experimental evidence would lead one to accept a slowly progressive neuritis as a manifestation of the virus of polio-myelitis.

CLINICAL RECORDS.

REFLEX STIMULATION OF THE VAGUS.

By W. J. MIDELTON, L.R.C.P.Lond., M.R.C.S.Eng., L.S.A.

In the Medical Press and Circular, December 11th, 1912, page 631, Dr. Brand published an article on reflex stimulation of the vagus. I decided to test the method, and have already published the results in some cases. For about two years I have attended a patient suffering from Graves's disease, but she did not improve until recently. On July 8th, 1913, amongst others she showed the following symptoms: General debility, palpitation, shortness of breath on exertion, pulse 104, blood pressure 180, wasting. I on that day applied the galvano-cautery in the neighbourhood of the 7th cervical vertebra over a small area. The patient did not attend as regularly as I wished, but aimed at coming once a week. By September 1st she felt much better, blood pressure 170.

September 16th, weight 7 st. 7 lbs., blood pressure 140; September 30th, weight 7 st. 9 lbs., blood pressure 140. Better in every way: in better spirits, greater capacity for exertion, much less palpitation, pulse 90. Although the stimulus was applied in a different situation from that recommended by Dr. Brand, the vagus is influenced nevertheless.

I feel very strongly that in counter-irritation we have a most valuable remedy, the possibilities of which are not sufficiently known, and it is too little practised.

While writing, I should like to say that I have read the following papers with very great interest.

Infectious Arthritis, Dr. Cooley, Medical Press and Circular, September 3rd, 1913, page 252.

The views expressed are, I am sure, destined to meet with wide acceptance and clear up much of the fog surrounding so-called rheumatoid arthritis.

Syphilitic Diseases of Joints and Bones in Childhood, Dr. Owen, September 17th, 1913, page 318. This paper goes admirably with the above and any general practitioner who will take the trouble to assimilate both thoroughly will be in a good position to give an accurate opinion.

A New Method of Treatment of Bacterial Infections, Prof. N. F. Surveyor, September 17th, 1913, page 323. This paper supplies much food for thought, but I will only comment on one portion. The author states: "In the paper mentioned above, I had stated that the staphylococcic vaccines, whether stock or autogenous, did not always give satisfactory results in cases of pyæmia, and it was suggested there that this might be due to the fact that there was infection with more than one microbe." In my opinion, this is a most important observation. Dudgeon showed years ago that peritonitis was often due to the pneumococcus and that if the staphyloccus albus was also present in the peritoneum the patient had a better chance of recovery than when it was not.

This seems to me to show that the staphylococcus albus is capable of destroying the penumococcus, and is a beneficent rather than malignant germ under certain conditions.

In the *British Journal of Children's Diseases*, July, 1913, Vol. X, pages 298-307, J. D. Rolleston gives an account of the treatment of diphtheria carriers with bouillon cultures of staphylococcus pyogenes aureus.

Summary.

"Ten chronic diphtheria bacillus carriers were treated by spraying and swabbing the throat or nose with a bouillon culture of (live) staphylococcus pyogenes aureus.

In six faucial cases the findings became negative within two to seven days after starting treatment. In two nasal cases the treatment was ineffective. In all but two cases a mild form of sore throat was produced, but no complication ensued." The subject, the antagonism of germs, has fascinated me for many years, and I am glad to see that good work is being done by those in a better position for observation.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

Epithelioma of the Tongue.—Mr. Willmott Evans operated on a man, æt. 53, who had been admitted suffering from an ulcer of the side of the tongue. The history of the case was that the ulcer had been present for about three months; the patient attributed it to the rubbing of a sharp tooth. On examination, on the left edge of the tongue, between the apex and the base, an irregular ulcer was seen with hardened edges, which were raised and everted. The hardness did not extend to the floor of the mouth. When the man made an attempt to put out the tongue, the organ could only be protruded for half an inch beyond the teeth, the tip being deviated to the left side. No enlarged glands were palpable under the jaw. A diagnosis was made of squamous carcinoma, and it was decided to remove the tongue through the mouth.

After the patient had been anæsthetised, a gag was inserted in the opposite side of the mouth, which was by this means fully opened. By means of a handled needle a stout ligature was passed through the apex of the tongue on the left side, the organ being forcibly drawn forwards. With scissors the tongue was slit down the middle as far as the circumvallate papillæ; then the mucous membrane of the floor of the mouth was divided on the left side; and lastly a transverse cut was made with scissors one inch behind the ulcer. Scissors were used to slowly snip through the tongue, and the lingual artery was caught with forceps as soon as it was cut through. No other vessel required ligature. The apex of the tongue was then carried back and fastened to the hindermost portion of the cut surface, and the mucous membrane sutured above and below the tongue, so that no raw surface was left. The surface of the tongue was then painted over with Whitehead's varnish.

Mr. Evans said that it was only in certain cases of epithelioma of the tongue in which the disease was strictly limited that a unilateral removal is possible or desirable. He pointed out that by the method he had employed of covering up all raw surfaces healing is greatly hastened and risk of septic pneumonia done away with. In a fortnight, he remarked, when the incisions into the tongue were completely healed, he would proceed to the removal of the submaxillary lymphatic glands, as he thought that performing the operation in two stages was preferable.

BIRKENHEAD CHILDREN'S INFIRMARY.

Cavernous Sinus Thrombosis of Nasal Origin—Operation—Death From Acute Meningitis.—Mr. **Adair-Dighton** operated on a child, æt. 6, which had been admitted to hospital in the afternoon with marked exophthalmos. There was a previous history of an accident some four weeks before, but no sign had been noticed until the night before admission, when the right eye commenced to bulge. Shortly after admission the patient had a rigor, the temperature reaching 103°, pulse 160, respiration 28. On examination there was marked exophthalmos in the right, and a dusky haze round the left eye; œdema was evident, there was optic neuritis in both eyes, and the child was comatose. Mr. Adair-Dighton said he considered it a typical case of cavernous sinus thrombosis, probably due to the accident having caused fracture of the anterior fossa, and infection having extended through this to the sinus. The prognosis was very bad, but as he had recently had a case of cavernous sinusitis of otitic origin recover, he did not consider it as hopeless as it was generally considered.

Under chloroform anæsthesia, he commenced by completely exenterating the right orbit, encountering foul-smelling pus in the region of the orbital plate of the ethmoid. After thoroughly clearing away all diseased tissue, he removed the superior wall of the orbital cavity from within one inch of the orbital margin in front to the sphenoidal fissure behind—*i.e.*, the orbital plate of the frontal bone and the greater part of the lesser wing of the sphenoid bone. He then lifted the right frontal lobe and curetted the cavernous sinus, concluding the operation by inserting a rubber drainage tube. The orbital cavity was dusted with orthoform powder, and a wet dressing applied. On the following day the temperature had dropped to normal, and hopes were entertained of the patient's recovery until the fourth day, when the temperature rose to 104°. Lumbar puncture was performed, and the spinal fluid was found deficient in carbohydrates. The child died from meningitis on the sixth day. At the *post-mortem* examination, the right cavernous sinus was found to be full of a septic thrombus, which extended for some distance along the superior petrosal sinus. The left cavernous sinus showed signs of early disease. The right frontal sinus was markedly diseased, and this had evidently extended to the ethmoidal cells, as these were extensively diseased, and communicated with the orbit by a fistula.

Mr. Adair-Dighton considered the case to be of particular interest, as it showed how one might be led astray by a previous history. In this case, one was led to expect fracture of the base, and the nasal condition was overlooked. It also conclusively proved that disease of the frontal sinus could occur at a much earlier age than was described, previous to Onodi's classical work, and further, it showed the path of extension from the nasal cavities to the orbit, and thence to the meninges which, in this case, was probably by direct contact plus the anterior, posterior ethmoidal, and ophthalmic veins.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

Section of Obstetrics and Gynæcology.

Meeting held October 9th, 1913.

The President, Dr. W. S. A. Griffith, in the Chair.

The Winter Session was opened by the **President**, who gave the introductory address.

Dr. **Macnaughton Jones** (London) read a short communication on

A CASE OF COMPLETE ABSENCE OF THE INTERNAL GENITALIA.

Dr. Macnaughton-Jones, in introducing his remarks on a case in which no internal genitalia could be detected, said that among other instances he had previously recorded was a case of complete absence of introitus in a child (a small orifice leading to the urethra); a rudimentary vagina and uterus were present, but no adnexa could be detected. He had also had a case in which the external genitalia were normal, the uterus rudimentary, and the adnexa present; and another case similar to the present one. The age of the patient was 27. Her health was good, and an examination was required as the question of marriage arose. As in the other cases, bi-manual, vaginal, recto-vaginal, and recto-vesical examinations were made. The external genitalia and vagina were normal; the uterus was represented by a nodule a little larger than a pea, and no vestige of adnexa could be felt. He dwelt on the importance in cases of primary amenorrhœa when menstruation was delayed of not putting off an examination. He had known cases (in one of which the patient had gone to Spa for treatment) where various remedies were used to induce catamenia when the genitalia were absent.

The paper was discussed by Dr. **Blacker** and Mr. **Douglas Drew**, the latter referring to a case where apparently, by pelvic and vaginal examination, no uterus, ovaries or tubes were present, yet at operation ovaries were found high up in the flanks together with a horse-shoe kidney in the pelvis.

Dr. **Macnaughton-Jones** also showed a specimen of pyosalpinx of an accessory tube from the adnexa of a patient, æt. 38, unmarried. The Fallopian tube at the right side was converted into an egg-shaped tumour, which contained a quantity of cretaceous matter, the result of an old pyosalpinx. At the left side the adnexa were healthy, but an exactly similar tumour existed at the outer edge of the broad ligament with histological features similar to that of the right side. The specimen was examined by Mr. Handley, and it was of interest as an instance of a cyst of an accessory Fallopian origin being converted into a pyosalpinx. At either side the cyst was incorporated with the round ligament.

He demonstrated by lantern the histological features present in accessory hydro-salpinx as originally described by Mr. Handley, and also some instances of accessory cysts he had himself met with.

Remarks were made by Mr. **Alban Doran** and the **President**.

REPORT OF TWENTY-THREE CASES OF ADNEXAL TUBERCULOSIS.

Miss **Ivens** (Liverpool) read a paper on adnexal tuberculosis based on the experience of twenty-three tabulated cases, of which all but one were apparently primary. An early diagnosis followed by operative treatment gave good results. The disease became much more serious when bowel complications had occurred. The history of an attack of obscure peritonitis in girlhood, followed by primary amenorrhœa, was given in four chronic cases, and partial or complete amenorrhœa was very common. Pelvic pain bearing no special relationship to menstruation was generally present, associated with leucorrhœa. Sterility was an almost constant feature, two patients only have borne each one child, many years previously. The majority were in the early twenties; fourteen were married. In every case a varying degree of thickening of the tubes could be felt. Only two were unilateral. Laparotomy was performed in twenty-two instances for the removal of the diseased tubes, the uterus being removed only for special indications. Conservative treatment of the ovaries was possible in all but six cases. In one resection of the tube for the removal of a tuberculous nodule was performed. Drainage was avoided except in the presence of a secondary infection, and primary union usually occurred. Two cases died, one of post-operative hæmatemesis, and one of septic nephritis. Sixteen were traced and did well. Three made a good immediate recovery, but were then lost sight of. One required a second operation for the removal of the remaining tube. The one case in which the disease was secondary died a year after operation.

Two cases came under observation with acute abdominal symptoms due to the rapid enlargement of pre-existing chronic cysts, where the disease had apparently undergone a spontaneous cure. Miss Ivens therefore advocated the operative treatment of all cases of adnexal tuberculosis, except in the presence of a second active focus, and considered that the removal of tuberculous products not only had a very beneficial effect on the general health, but at the same time obviated the risks of later dissemination or local complications.

The paper was accompanied by a detailed analysis of the cases, together with microphotographs, the latter being demonstrated on the epidiascope.

Dr. BRIGGS (Liverpool), who alluded to the chronic character of Miss Ivens' cases, said that in more acute cases, which had some clinical resemblance to typhoid fever, operation seemed imperative. In the majority of cases there are tubercular foci elsewhere, and their aggravation or relief by operation cannot be locally governed.

Mr. DOUGLAS DREW said that he had considerable experience in the question of operation for tuberculous peritonitis in children, but had not met with a case in which there was disease of the tubes. Possibly in Miss Ivens' cases tuberculous peritonitis was an antecedent factor. Mr. Drew asked in what percentage of cases a tuberculous endometritis was present. Possibly it was of frequent occurrence, but appeared to recover spontaneously after the main lesion was removed.

Dr. MACNAUGHTON-JONES remarked that a few years back he had read a paper before the Section on "Primary Tuberculosis of the Fallopian Tube," and had shown three specimens, and he referred to another paper which appeared in the *Edinburgh Medical Journal*, in which statistics were collected of many thousand cases of genital tuberculosis. In these eight to nine per cent. were primary. In young persons, seeing the difficulty of diagnosis, every test for the presence of tubercle should be made. In Miss Ivens' cases the greater number were under 30, but 40 per cent. remained well some considerable time after operation.

In reply, Miss IVENS stated that her cases included types of both active and chronic disease. Tuberculous endometritis had been found once, but systematic curettage had not been practised, as leucorrhœa tended to disappear after removal of the diseased tubes. It was possible that in cases where tuberculous peritonitis had occurred in childhood the infection remained latent to become active with the onset of puberty. Miss Ivens thanked the speakers for their remarks, and was grateful for the criticism of that eminent authority on pelvic tuberculosis, Dr. Macnaughton-Jones.

Dr. R. L. MACKENZIE WALLIS and Dr. HERBERT WILLIAMSON read a paper on

THE SERUM DIAGNOSIS OF PREGNANCY, WITH A DEMONSTRATION OF APPARATUS AND METHODS.

The paper was read in two parts, Dr. Mackenzie Wallis taking the experimental chemical department, and Dr. Williamson the clinical aspects.

In Part 1, Dr. Wallis dealt with the two methods devised by Abderhalden for the diagnosis of pregnancy—namely, the optical test and the dialysation method. The principle upon which these two tests is based is the reaction of the blood to foreign substances introduced from without. Any foreign body when injected into the circulation excites the production of a protective or guardian ferment, which rapidly destroys the substance. The proteins contained in placental tissue thus produce a specific ferment, and this can be detected in the blood serum of pregnant women by both methods from the seventh week and up to fifteen days after labour. The tests depend, therefore, upon the presence of chorionic villi in the body, which are capable of being washed into the circulation and producing the special ferment necessary for their disintegration. That such a ferment is mobilised in the blood has been conclusively shown by experiments on animals. For the optical test a good polarimeter was required, and also a preparation of placental peptone, the details of the isolation of this material being given. The splitting of this placental peptone into amino-acids by the ferment in the blood serum could then be followed by the optical changes that ensue. The *technique* employed by the writer in the dialysation test was given in detail, including the preparation of the placental tissue, the testing of the dialysing tubes, and the collection of the serum. The necessity of absolute asepsis throughout was especially emphasised. The application of the ninhydrin reaction for the detection of dialysable substances was described, and attention drawn to the sources of possible errors. Judging from the results obtained with over 100 cases, the writer had no hesitation in stating that the test was of value in the diagnosis particularly of the following conditions: (1) The diagnosis of early pregnancy, (2) the differentiation of fibroids from pregnancy, (3) the diagnosis of chorion epithelioma, (4) the presence of a retained placenta, (5) the diagnosis of an ectopic pregnancy, where the latter has not been followed by tubal abortion and hæmatocele.

In Part II. of the paper, Dr. HERBERT WILLIAMSON (London) pointed out the importance of Abderhalden's work, remarking that if it be true that the blood of a pregnant or recently delivered woman contains a ferment specific to placental albumin, if this ferment be constantly present and can be easily demonstrated, if the sources of error are few and can be readily avoided, the test possesses great value in both clinical and forensic medicine. He reported a series of 50 controls made by Dr. Mackenzie Wallis. Of these, 20 women were either in the last three months of pregnancy or had been recently delivered. In every case the result was positive. Thirty women were not pregnant, and in all these patients the reaction was negative. He then proceeded to give clinical details of 16 cases in which the test had been applied for diagnostic purposes. The patients had all been kept under observation and the results were:—Correct deduction drawn from the test, 12; incorrect, 2; result still in doubt, 2.

The cases were as follows:—Suspected ectopic gestation, 3; pelvic and abdominal tumours where it was suspected that the whole or part of the tumour might be the pregnant uterus, 5; suspected chorion-epithelioma, 2; chorea in a woman of 21, 1; heart disease with amenorrhœa, 1; nephritis with exacerbation of symptoms and amenorrhœa, 2; late puerperal sepsis, 2; total, 16.

The two patients who gave a positive reaction in the absence of pregnancy both suffered from pyosalpinx, and this suggested the advisability of ascertaining whether a similar result was common in suppurating cases. The controls made did not support this view.

The author insisted upon the importance of subjecting at regular intervals to Abderhalden's test all patients who have borne a hydatidiform mole, for should a chorion-epithelioma develop the test remains positive instead of becoming negative in a few days as after a normal pregnancy. This fact was well illustrated by the case (which he quoted in detail) of a woman who developed the symptoms of chorion-epithelioma fifteen months after the expulsion of a mole.

From his experience he drew the following deductions:—(1) It is established that the serum of pregnant women contains a ferment specific to placental albumin; (2) that this ferment can be demonstrated from the eighth week of pregnancy until ten days after delivery; (3) that it may be demonstrated both by the polarimeter and by the methods of dialysis; (4) that the former method is more reliable, in that the sources of error are fewer; (5) that the accuracy of the test depends upon the most scrupulous care in detail, and it is only in the hands of an expert that the results can be relied upon; (6) that the ferment is found only when chorionic tissue is present in the body; (7) it is probable that under certain conditions not fully understood at present, the colour-reactions and optical effects produced by the ferment may be simulated; (8) that the common sources of error have already been detected, and that in the near future the test may be expected to give reliable results.

The two papers were discussed by the PRESIDENT, Dr. ARCHIBALD GARROD, Dr. BLACKER, Dr. EMBLEDON, Dr. LEITCH, Dr. DONALDSON and Dr. BOURNE.

Dr. WALLIS and Dr. WILLIAMSON replied.

NEW DERMATOLOGICAL SOCIETY OF LONDON.

OPENING MEETING OF THE SESSION, HELD THURSDAY, OCTOBER 9TH, 1913, AT THE WESTERN SKIN HOSPITAL, HAMPSTEAD ROAD, LONDON.

The President, DR. DAVID WALSH, in the Chair.

THE Hon. Secretary (Dr. NORMAN MEACHEN) read the minutes of the last meeting, which were duly confirmed and signed.

Dr. C. G. Mack was elected hon. secretary in place of Dr. Meachen, whose term of office had expired.

Dr. A. EDDOWES proposed hearty thanks to Dr. Meachen for the work he had done for the Society as Secretary; he knew how arduous such duties were, from his own experience. This was seconded by Dr. VINRACE.

DEMONSTRATION OF CASES AND DISCUSSION ON LICHEN PLANUS.

Dr. MEACHEN showed two cases. The first, a woman, æt. 38, single, with an eruption over the whole body. It was of six years' duration, and had never quite disappeared. The irritation was intense, and when he saw her at the Prince of Wales's Hospital there were many features resembling exfoliative dermatitis. Close inspection, however, revealed lichenoid elements, and there were confluent patches on neck and limbs. There were no mucous membrane lesions. It was said to have commenced under the garter on one leg, and that focus was still present. To his knowledge she had had no arsenical treatment before he saw her. There was a history of much mental worry and trouble before the eruption occurred. It was now retrogressing under treatment. At first it looked like seborrhœa corporis. In the second case the eruption appeared at first as a bulla, and such a lesion could now be seen on the ankle, but the following week there were lichenoid lesions on the dorsum of the foot, the inner side of the knee, and the flexor surfaces of the arms. She now showed the typical distribution. Her age was 49, married, and the duration was two months.

The PRESIDENT showed a woman, æt. 65, who had had the condition six months. Typical patches were evident on the legs and the inner side of the thighs. There was much irritation. When a child, she had scarlet fever and what was spoken of as "brain fever"—doubtless meningitis. For 25 years she had had some cough and bronchitis.

Dr. EDDOWES showed a woman with a follicular inflammation which frequently led on to lichenisation, but was not a case of lichen planus. Hairs came out of little red points. She had not been under his treatment long, but already the character of the eruption had altered. Little papules outside the main patch looked much like lichen planus, but a lens soon showed that hairs came out of the centre of these follicular lesions. This condition he believed to be rather common. This patient had been ill two years, and just before then was said to have had rheumatic fever and blood poisoning, and had had neuritis. For two years she slept badly, and had distressing dreams. This was a case of specific trouble, and she was getting better under mercurial treatment, chiefly local. The tendency for such cases to show lichenisation made them instructive when compared with actual lichen planus. He had notes of a similar case which he saw in 1902, with a microscopic section, and he believed a section of the present case would present a similar picture.

Dr. H. C. SAMUEL showed the case of a woman who came to hospital with a widespread eruption all over the trunk, arms and legs. She had had much worry. A patch was found on the thigh which she had had four or five years. Four years afterwards it lighted up, and she had an acute outbreak, and that was why he was exhibiting the case. She was now improving.

His next case, also a woman, he showed as dermatitis bearing a resemblance to lichen planus. It was really a peri-follicular condition, and it gave no impression of infiltration. There were no definite papules, and no lesions in the mouth. The patient was a seborrhœic subject. She had been treated as a case of dermatitis.

Dr. D. VINRACE showed a girl æt. 7 who had had lichen urticatus from the seventh week of life, to illustrate the lichenoid appearance of the lesions frequently seen in this disease.

The PRESIDENT then introduced the discussion on lichen planus, which will be found fully reported elsewhere in the present issue. See page 443.

Dr. ALFRED EDDOWES remarked that he at first thought it would have been good to have a discussion on lichen, but he now thought that would have been too wide a subject for one debate. The flat papule was greatly due to the position on the surface of the skin where the hair follicles were well marked. This tended to obscure the fact that the lichen planus began above the sweat pore and duct. The affection, indeed, seemed to be connected with the sweat apparatus. One seldom saw distinct lichen planus on the face. They were nearly always plugs, which the patient scratched out; and they were sometimes called grubs, or sand. Where the follicles were well developed, one saw the accuminate or obtuse form of lesion. The flat papules were best seen where the sweat areas had little or no hair.

With regard to the pathology, he had examined many sections over a number of years, and the hypertrophy of the horny layer was very distinct. In the granular layer the number and size of the cells was increased. The cell-infiltration occurred particularly in the papillary layer, and the sweat ducts showed the same. The sweat pores were often found to be filled with a horny plug. It was necessary to study the grooving of the skin, as that was where the hairs particularly grew. Distension and degeneration of the sweat gland could often be seen, showing the profound disturbance of the sweat apparatus. Sections taken should lie, as far as possible, in the plane of the ducts and pores; otherwise a papule might be shown in a section without its corresponding sweat gland. If sections were too thin, they contained only portions of the spiral duct. The hair follicles might also exhibit cell-infiltration, and this had often attracted too much attention, as it occurred only secondarily. He had brought a number of sections of lichen planus and other lesions somewhat allied, some of which he had diagnosed as pityriasis rubra pilaris.

Lichen planus came out after scabies. Why? Probably the patient was ready for some traumatism to develop the skin condition. The attack might have come on for some other reason. If there were 50 per cent. shock and 50 per cent. traumatism, the rash might come out. There was a personal peculiarity in the skin which might lead to eczema in one case, and lichen planus in another.

DR. SAMUEL said he was under the impression that most of the material in the sweat ducts was hyaline, except in cases of lichen verrucosus. With regard to umbilication in the papules, there were two points of view. Some thought the umbilication was due to a sweat pore, while others said it was due to contraction of the hyaline material. He was in favour of the sweat duct view, because the papules were marked by the natural grooves of the skin, and the patches corresponded with the sweat ducts. The opening was due to the sweat pore.

With regard to treatment, some preferred to inject orsudan and soamin. Nervous shock as an ætiological factor had not impressed him very much; it was easy to get such a history from most people if one asked for it. The amount of itching in the disease was very variable, but it was sometimes given as a point in diagnosis. He believed it depended largely on the nervous stability of the patient. Many patients with lichen planus did not complain of itching at all. He was uncertain whether X-rays brought about improvement by relieving the itching and permitting spontaneous involution, or by influencing for good the disease itself. When bullæ formed, were they due to the arsenic, or not? In some cases in which arsenic had not been given bullæ appeared. The same remark applied to pigmentation, which likewise had been said to be due to arsenic. Pigmentation depended on the intensity of the lesion and the degree of itching.

He suggested that there might be a causal organism of some sort in lichen planus, for its behaviour resembled that of syphilis in many ways. Lumbar puncture had been employed by Pernet to relieve pruritus; it certainly relieved the itching for days, and the disease tended to get better because there was no more scratching.

Dr. Meachen said this question was brought before the Dermatological Society of London 13 years ago, and the late Dr. Radcliffe Crocker chose it as the subject of his address. It was somewhat of a reproach to dermatology that our knowledge of its pathology had not advanced in the meantime. The subject was so vast that one could not expect to discuss every point concerning it. His remarks would be limited to two features. There were anomalous forms of the disease, which rendered diagnosis difficult; it was easy enough to recognise a case when the characteristic lesions were in the classical situations. Sometimes the lesions were annular, often slightly papular. He showed the photograph of a woman, æt. 51, who had had the annular form of lichen planus eight years. It looked like an old syphilide. That case responded very well to arsenic—it was seen in the pre-Wassermann days. One saw the so-called lichen streaks following upon scratching; and Sherrington and Baker had suggested the neurotrophic origin of the disease from that feature. Lichenification occurring in scratch marks was common. Cases of scabies sometimes passed into lichen planus. It only partially yielded to sulphur, and then one saw the typical lichen planus lesions appear. Another anomalous form was that in which bullæ appeared, and the vexed question arose as to whether the bullæ were consequent upon the arsenic or independent of it. Dr. Crocker said the answer must be given in the affirmative, and the position seemed to be the same still. Sometimes bullæ preceded the appearance of papules. In the elderly married woman shown by him that day the first evidence was a large bulla on the external malleolus, and she had a few smaller bullæ on the palms. After these, came the characteristic lichenoid papules on the flexor surfaces. About a year ago he showed a case of lichen planus before this Society where there had been much irritation, and in which every lesion upon the legs became vesicular. He believed that patient had morbus cordis. Kaposi had an instance in which bullæ appeared without any arsenical treatment at all. Two facts, therefore stand out prominently. First, there was a local irritation—as shown by several cases at that meeting—and then there was mental and nervous strain. It was quite common after a severe nervous shock. Dr. Whitfield had reported the case of a cyclist who rode all night in the pouring rain. He got not only a chill but a nervous shock, and next day he had a profuse eruption of lichen planus. Others would recall lichen planus having occurred after the loss of a near relative of the patient. Bichloride of mercury was a favourite drug for the disease in America. If his cases did not improve on arsenic, he put them on liquor. hydrarg. perchlor. He did not see why salvarsan should not do good in lichen planus.

Dr. Vinrace said one heard that lichen planus was a condition which arose when the skin had been prepared by other ailments; but there was no condition he knew of like syphilis for upsetting the cutaneous surface of the body. On the theory just mentioned, however, one would expect lichen planus to be a frequent sequel of syphilis; yet he had not seen more than one or two cases in which that was so. He had one old case of syphilis which developed lichen planus in the scapular region.

Dr. C. G. Mack pointed out that none of the speakers had discussed the question of predisposition, and mentioned that, years ago, he discussed with Mr. Bruce Clarke the question of predisposition to cancer; why one man could smoke a clay pipe for forty years and never develop cancer of the lip, whereas another developed it after only fifteen years' similar indulgence. One line of research in the future would be to ascertain each person's predisposition and liability.

Dr. J. D. P. McLatchie pointed out that one girl with lichen planus used to get much relief from the irritation by bathing the lesions with her own urine.

The President, in replying to the discussion, said one repeatedly heard a history of shock in cases of lichen planus, and examination of subjects of the disease showed them to have signs of nervousness. He never used arsenic in treatment, but invariably employed perchloride of mercury, beginning with ½ drachm or 1 drachm. He had had opportunities of comparing his results with those of his colleagues who used arsenic, and the comparison was favourable to his remedy. The practical point was the ability to allay the irritation, for that permitted sleep and the recovery of the nervous system. One of the best antipruriginous lotions was carbolic acid and tincture of camphor.

CENTRAL MIDWIVES BOARD.

Meeting held October 9th, 1913.

Sir Francis Champneys in the Chair.

THE INSURANCE ACT AND THE MIDWIVES ACT.

The correspondence included a letter from the Clerk of the Council transmitting a copy of a letter from the National Health Insurance Commissioners on the effect of the working of the Insurance Act on the administration of the Midwives Act.

Letters were read from the Deputy Coroner for the West Riding of Yorkshire calling the attention of the Board to the fact that premature birth is not one of the cases specifically mentioned in the Rules as imposing on a midwife the obligation of advising medical assistance, and asking the views of the Board on the subject; and from the Clerk of the Derbyshire County Council suggesting that a rule should be framed under which midwives would automatically cease to be enrolled on attaining the age of seventy.

In reply to both these communications, it was agreed that the suggestions contained in them should be brought up at the next revision of the Rules.

The Staffordshire Training Home for Nurses was approved as a place where training might be done, but the doctor and midwife must be individually approved.

William Ardendt Hagestadt Watte, M.B., and Thomas Thomson Rankin, M.D., were approved as teachers. With reference to one of the applications which were refused, Mr. Parker Young entered a protest. Recognition for this purpose does not depend merely on the suitability for a teacher of the applicant, but on whether the Board, which is not anxious to multiply training centres, considers the district in need of another teacher. Mr. Parker Young was only supported Sir Shirley Murphy, so lost his amendment.

The Secretary's report on the last examination showed a total of 315 candidates, with a percentage of failures amounting to 17.4.

Miss Paget inquired whether any steps had been taken to ascertain if a woman described in the Press reports of the proceedings as connected with a recent prosecution for an offence under the Criminal Law Amendment Act in Piccadilly was a certified midwife as had been asserted, and, if so, whether it was contemplated to cite her to appear before the Board. The Secretary had ascertained that the woman was on the Roll, and the matter was referred to the Penal Cases Committee.

Penal Boards will be held on November 6th, 11th and 12th.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, Oct. 18th, 1913.

At the Verein der Aerzte, Wiesbaden, Hr. Baer read a paper on the

Extension of Operations within the Bladder.

At present such operations were limited to operations for stone, foreign bodies and tumours. In classes 1 and 3 he demonstrated operations that had hitherto been considered unsuitable for intravesical operation. One was a hairpin that was encrusted with a calculus the size of a walnut, removed from the bladder of a girl seven years of age. The operation would have been performed by the sectio alta method, but the father of the child refused to have the operation performed. Thanks to Roentgenography, the calculus was accurately localised, and the extraction done by lithotripsy performed through an endoscopic tube. The figures shown were (1) the hairpin with the stone lying transversely and filling the small pelvis; (2) the pin freed from the stone, (3) the pin and stone after removal.

The second case was that of a tumour. The high-frequency current was at first tried, and in the opinion of the speaker was well worthy of further development, but it could in no way be a substitute for the écraseur. When made use of through the speaker's pancystoscope it could be applied from any direction and without injury to the walls of the bladder. The universal freedom of movement of his apparatus enabled him to operate in the following case, one of vesico-vaginal fistula. The patient was 26 years of age. She had had several difficult labours, and after the last one a vesico-vaginal fistula resulted. She remained under gynæcological treatment for a long period, and when she would submit to this no longer she passed into the hands of a specialist in bladder diseases (Dr. Bastos, of Lisbon). All methods of treatment short of operation were tried in vain. The speaker, called to Lisbon by Dr. Bastos, there constructed a small apex cautery specially for the case, and made out of his movable loop carrier, with which the fistula was cauterised through his pancystoscope. The good freshening up of the wound in that way promised, as he thought, a good prospect as regarded healing. The operation lasted about 15 minutes. A retention catheter was left in the bladder. From the end of the second week the fistula remained permanently closed. The operation had now been performed over a year ago. In the opinion of the speaker the operation was only suitable for the treatment of small fistulæ.

A discussion followed the reading of the paper, in which Hr. Stein said that the treatment of tumours of the bladder by the high-frequency current that had been touched on by the reader of the paper afforded a particularly good prognosis. For the destruction of malignant tumours of the bladder wall diathermia was eminently suited, as it acted more rapidly, more intensively, and with greater certainty than the cautery. For the removal of papillomata it did not come into consideration so much. He pointed out the fundamental distinction between diathermia and fulguration, the latter having been introduced in error.

Hr. Baer thanked his colleague for his friendly criticism and for the suggestion to make use of the high-frequency current, which he thought promised so much for the treatment of tumours of the bladder. He had not rejected that form of treatment; on the contrary, he had recognised its value when he said, "The high-frequency current is a valuable complement of treatment, but it is not a substitute for the cautery-écraseur." Both methods were to be used together, or in common. The high frequency would be applicable in his opinion in (1) small multiple new growths, (2) later treatment of unfavourably situated pedicles, (3) many malignant growths unsuitable for bloody operations, (4) many malignant tumours where bloody operations were declined.

AUSTRIA.

Vienna, Oct. 18th, 1913.

The Therapeutic Value of Phosphorus in Rickets.

The final results and conclusions of the late Prof. Max Kassowitz on the subject of rachitis have just been published. He had made the subject a special study for fully thirty years, and his latest facts and reasonings show little deviation from those set forth in his earliest publications on the subject. He had arranged his ultimate data and the opinions based thereon under the following general rules of clinical observation and practice:—(1) Numerous observers on whose reasoning powers and reliability of statement no doubts can be thrown have demonstrated in the most conclusive manner that in the treatment of the osteal alterations and nervous lesions of rachitic patients they have obtained the same therapeutic results from the medicinal administration of preparations of phosphorus without cod-liver oil, as with the combination of both those agents. (2) The same conclusions were arrived at from the general reasoning processes adopted in 1884, and the latest clinical data obtained from his experimental researches on the same subject. (3) It is utterly impossible to draw any conclusions regarding the processes which are taking place in the osseous system from the continually fluctuating results of calculations of the calcium equilibrium, which are mainly based on examination of the intestinal contents. (4) The view that the phosphorus stratum, which was experimentally produced by this author, is formed merely from the calcified cartilage, is an utterly groundless one. (5) There is no scientific proof that the alterations in structure of the opposed surfaces of adjacent bones, which are produced in mammals and fowls by the administration of small doses of phosphorus, cannot be also produced in healthy children by corresponding methods.

Relationship of Duodenal Secretions to Catarrhal Jaundice and Gastric Lesions.

Dr. J. Matko has found, in his researches on the contents of the duodenum in cases of catarrhal jaundice, that in some cases there is an increase of the secretion, chiefly from the duodenal mucous surface. Researches were simultaneously carried out on parallel lines regarding the presence of trypsin in the "oil breakfast" and in the alvine evacuations; on the appearance of the aldehyde reaction in the latter and in the urine; and on the occurrence of alimentary dextrosuria and galactosuria. These investigations displayed results which led to important conclusions regarding the liver and pancreas in their functional relationship to the simultaneous processes that happen to be taking place in the duodenum, and more especially around the papilla of Vater. It was found that alimentary dextrosuria could be present simultaneously with either an increased or diminished secretion of trypsin. In three cases of undoubted duodenal ulcer there was found in each, on administration of Volhard's breakfast, a copious quantity of intestinal juice—mingled with which was a notable quantity of biliary secretion, the collective secretion also displaying an extreme tryptic activity. This wealth of digestive juices was attribued by Dr. Matko to hypersecretion of the duodenal glands, with coincident hyperactivity of the pancreatic acini leading to the formation of great quantities of trypsin. This influence on the experimental results of the fat breakfast is not found in cases of peri-duodenal affections, of gastric or of pyloric ulcer.

The Influence of Pituglandol on the Progress of Labour.

Dr. Hugo Bosse has published the results of his researches regarding the clinical value of pituglandol (Roche) during labour. They have demonstrated the fact that this is a trustworthy and wholly innoxious anodyne agent in the stage of dilatation of the os uteri; and, even more especially, during the period of the expulsion of the fœtus. In combination with pantopon, or with pantopon-scopolamin, it secures a painless and rapidly progressive labour. When operative procedure is found necessary to the completion of the labour, it should always be previously injected as a prophylactic agent, inasmuch as it acts as a preventive of post-partum atony of the uterus.

Application of Serology to Psychiatry.

Dr. Fauser has published a remarkable communication on the use of serological procedure, and more especially of the Aberhalden method, in psychiatry, and records his observations of a number of cases in which this method furnished a fully reliable differential diagnosis of dementia præcox. In dementia præcox there is usually defective function of the germinal glands and of the brain.

HUNGARY.

Budapest, Oct. 18th, 1913.

On Lumbago.

Dr. Tauszk says that persons with a tendency to lumbago should refrain from cold baths and fatiguing exercises. He has encountered cases in which the lumbago developed in connection with a series of gymnasium exercises. The chief characteristic of lumbago, he said, is the tendency to recurrence. In some cases the trouble is unsuspected fracture of the transverse process of some vertebræ. In other cases he has been able to discover a tender point in the psoas iliacus muscle on one side, palpating down from the attachment of the muscle on the trochanter. When this is the case attempts to flex the thigh against resistance are painful. The old lumbago is thus revealed as having its seat not in the back, but in the front. The discovery threw retrospective light on a number of puzzling cases in his practice. As with sciatica, the spine frequently shows curvature from the affected side. the affected muscle being relaxed as with rheumatic torticollis. In some cases of lumbago there is accompanying neuralgia in the pelvis, especially in the sciatic nerve, and this should be regarded in treatment. He advises examination during a free interval, seeking for the almost inevitable tender point, and until treatment succeeds in restoring normal sensibility here there is little prospect of a permanent cure. Rest and warmth are the main factors, and he has the patient apply a hot water bottle to the seat of the sensitive point on retiring, taking internally at the same time 0.5 or 1 gm. hydropyrin. In very severe cases the patient should stay in bed. An orthopædic corset may be found useful (as advised by Hansen, of Christiania), and this or a plaster cast is absolutely necessary in traumatic lumbago; it may save the patient much trouble and discomfort later. Massage of the tender points is a further aid in treatment, but it should be done by skilled hands on a systematic plan, and repeated at intervals during two or three months. It should be commenced very gently, as, done carelessly, it may do more harm than good. The massage is most effectual with the patient reclining, or partially reclining, with flexed knees.

Injection of Paraffin for Incontinence of Urine.

At the Medical Society, Dr. Illyes reviewed the history of injection of paraffin around the urethra in cases of laceration or other lesion of the sphincter, inducing insufficiency, first introduced, he said, by Gersuny in 1900. Illyes has applied the method himself in one case, and compares the outcome with that in twelve other cases on record. Continence was constantly secured by the procedure, which in several of the cases was the last resort after failure of all other measures. The final outcome is known only in two of the cases—in one of Gersuny's after an interval of three years, and in Illyes's case, after nearly two years. In the latter patient, a woman, æt. 34, the paraffin was found apparently unmodified at the points injected, answering its purpose just as well after nearly two years as it did at first. He injected a total of 9 or 10 gm. of paraffin with a melting point of 77° C., at five sittings. The fluid paraffin was taken up into the syringe, and was allowed to cool to the consistency of a thin salve to avoid the danger of embolism. The incontinence in his case was due to laceration of the urethra during childbirth. The urine still dribbled nothwithstanding several operations during the five years afterward striving to restore normal conditions in the urethra.

Nerve Anastomosis for Facial Paralysis.

Dr. Doronyi reports a case of old and severe facial paralysis in a robust man of 28. He sutured the peripheral stump of the facial nerve to the central stump of the spinal accessory nerve, and then sutured the central stump of the facial to the spinofacial junction thus made. The results were extremely satisfactory, he said. He tabulated or summarised more fully the details of eighty-five cases of nerve-grafting operations on the facial which he has found on record, grouping them according as the anastomosis was made with the accessory or the hypoglossal nerve. This list included five operations of the kind done in Hungary during the last five years.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

EDINBURGH.

Chair of Clinical Medicine, Edinburgh.

At a meeting of the Joint Committee of the Infirmary and University Court, held last week, Dr. William Russell and Dr. Graham Brown were selected from a list of applicants, and their names will be submitted to the Court, which is meeting on the 20th inst., to make the appointment.

Edinburgh School of Medicine for Women.

A new anatomy department was inaugurated in connection with this school on October 17th. The Dean of the School, Dr. William Russell, before calling on Sir William Turner, said that this was the sixth year that the School had been housed in the College of Surgeons. When Minto House was sold, some had thought that the School would come to an end, but the lecturers had stepped in and been entrusted by the University Court with the conduct of the medical education of women. The Carnegie Trust had now come to their help, and furnished them with an excellent, well-equipped bone room and dissecting room. Another important step forward had been made in the appointment of women demonstrators in anatomy and physiology. Sir William Turner declared the rooms open, and expressed the pleasure which it gave the Court to see the admirable new accommodation provided for the women studying anatomy.

New Pavilions for Consumption in the Edinburgh City Hospital.

So long ago as 1906, accommodation for pulmonary tuberculosis was provided by the local authority in the Edinburgh Fever Hospital, and since then the number of beds, only for advanced cases, has increased from 50 to 82. After the Insurance Act came into force, it devolved on the Town Council to provide for the disease in all its stages, and as the Colinton Fever Hospital had 700 beds, of which never more than 400 were occupied, it was decided to utilise the accommodation there for the treatment of phthisis. An arrangement was therefore made with the Insurance Committee to take over their cases at the rate of 25s. per week, and therefore a sanatorium has been made by adding to two of the ordinary pavilions open air shelters of modern type. Eighteen of these have been provided at a cost of £25 each.

There have also been built two large pavilions for 60 patients at a cost of about £4,000. They are built of red wood, with asbestos tiles, and are in the form of loggias, with the usual dressing rooms and service rooms, and ample balconies. There are also a recreation ground and a small golf course, and a scheme of extensive tree planting for shelter has been begun. The patients are under the general supervision of Dr. C. B. Ker, Medical Superintendent, and Dr. James, Consulting Physician to the hospital. It will be possible to grade the patients effectively and to separate completely early, intermediate, and late cases. The last named will, as before, be accommodated in the old stone pavilions, the upper wards being reserved for patients who are so ill that recovery is not to be expected. The new loggias are reserved for early cases, and the shelters for convalescents. At present, there are about 100 patients in hospital, of whom 40 are uninsured persons sent in at the request of the Medical Officer of Health. The total available accommodation amounts to about 180 beds, so that there is still considerable margin.

GLASGOW.

Medical Problems in the Cure of Certain Diseases.

Dr. T. K. Monro, the recently appointed Professor of Medicine (and author of the popular "Manual of Medicine," 3rd edition), delivered his inaugural lecture on October 13th, at the University, and was introduced by Principal Sir Donald Macalister. Professor Monro, in the course of his lecture, indicated some of the important steps by which the science and art of medicine had been advanced, and spoke of some of the medical problems which urgently pressed for solution at the present time. It might, he said, seem a bold thing to some of his hearers to contemplate with any degree of hopefulness the probability that certain diseases which at the present time caused many deaths might be abolished altogether or reduced to a position of relative insignificance in the mortality statistics; and yet that was no unreasonable optimism, as past history and even the experience of the present generation could testify. He instanced the cases of scurvy, leprosy, small-pox, malarial fever, and typhus fever, and he alluded to the enormous reduction which had taken place in the prevalence of tuberculous in England and Wales since Queen Victoria came to the throne in 1837, and in Glasgow during the last half-century.

A Medical Lady Militant.

The proceedings at the sitting in Glasgow of the High Court of Justiciary, on the 15th inst., were diversified by the trial of two suffragettes, one of whom was a lady doctor, Mrs. Elizabeth Dorothea Chalmers Smith. The charge was that of breaking into a west-end mansion and placing certain materials in it with a view to burning the house. The house in question was empty, and was last occupied about ten years ago as the town residence of Sir John Muir, Bart., of Deanston, a former Lord Provost, since whose death it has been in the market. The ladies obtained admission to the house for the pretended purpose of viewing it, and one of them contrived to remain secreted in it. At the trial the prisoners refused the aid of counsel and called no witnesses for the defence, but at the conclusion of the evidence for the Crown argued that there was no case to go to the jury on the legal point of view. The jury found the prisoners guilty, and they were sentenced to eight months' imprisonment. On hearing the sentence, the fashionable and other ladies who thronged the court discharged a fusillade of miscellaneous missiles at the Bench, but did no damage. Three of them were apprehended and will be tried on a charge of assaulting the judge.

The Question of an Inclusive Fee in Medicine.

The extra-mural medical schools are to hold a meeting of representatives shortly, with a view to returning a joint answer to the University's proposal for the institution of an inclusive fee in medicine.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

A PRACTICAL CONSIDERATION OF VACCINE THERAPY.

To the Editor of The Medical Press and Circular.

Sir,—Let me thank your correspondent, Dr. Gabriel, for his very reasonable and apposite question.

The comparison of a vaccine with a dog licking his wound was employed more as a suggestion than as an assertion of fact.

Subjects of pyrrhœa alveolaris generally suffer with more or less constitutional disturbance, of which the pyorrhœa is only a part or link in a vicious circle, and in which a great variety of bacteria are concerned.

But the dog has only a local trouble, and, otherwise presumably healthy, he by licking his wounds may possibly increase his natural immunity during the healing process.

The administration of vaccines by the mouth is still uncertain, and no precise details have at present been established; for the journey of a vaccine from the mouth to the portal blood is necessarily attended by many complications which the more precise method of subcutaneous injection does not involve.

I am, Sir, yours truly,
Wyatt Wingrave.

London Polyclinic,
October 17th, 1913.

THE TEACHING OF SCIENCE.

To the Editor of The Medical Press and Circular.

Sir,—My three boys are now grown up. Twins, aged 23, have finished their education, save for final professional examinations; and the third, aged 21, doing his third year at Cambridge. Before the boys were born, and during the whole period of their growth and development, I gave my best thought to the question discussed in the excellent letter of your correspondent, "L.," in your paper of this week. I would like first of all to call his attention to an article on the subject which appears in the October number of the *Parents' Review* (price sixpence), the organ of the Parents' National Educational Union. It is the wisest, the best-informed, and the best-expressed plea for classics that I have ever encountered. I am ashamed to confess I have forgotten the name of the writer, and, being away from home, I am unable to refer to it. My own opinion is that if a lad has the intellect needed for a scientific vocation, and unless he shows a reasoned antipathy to classics, it will be very much better for his educational and intellectual development if he take up classics, and continue them concurrently with science. Of course, if we want to give a purely narrow utilitarian education, one that may enable the lad to begin to earn money very early, it may be necessary to lead him to so far specialise at the outset. But if we want the lad to be an accomplished professional man in whatever vocation he may finally select, with a wide intellectual horizon, and with the capacity to get out of life the pleasures that wide intellectual interests alone can give, we cannot I believe, do better than make classics an essential part of his education. The teaching of science at all our public schools has vastly improved in late years. My sons were at Tonbridge, and there the laboratories and the apparatus leave little to be desired. There, as well as at many similar schools, the boys can get all the instruction needed to start them on a scientific career.

I am, Sir, yours truly,
Paterfamilias.

Fowey Hotel,
Fowey, Cornwall.
October 9th, 1913.

P.S.—I have brought with me the second volume of the lately-published "Diary of Lady Frances Shelley," and since posting my letter I have come across the following passage (p. 128) in a letter from the great Duke of Wellington to Lady Shelley. The Duke is giving advice with regard to the education of her son for the military profession. It is interesting to note his insistence upon the importance of classics. "If," writes the Duke, "he means to rise in the profession, he must be a master of languages, of mathematics, of military tactics, and of all the duties of an officer. He will not be able to converse or write like a gentleman—much less to perform with credit to himself the duties on which he will be employed—unless he understands the classics, and by neglecting them, moreover, he will lose much gratification which the perusal of them will always afford him; and a great deal indeed of professional information and instruction."

SOME MISCONCEPTIONS OF OZONE.

To the Editor of The Medical Press and Circular.

Sir,—My attention has been drawn to the paragraph which appeared in your issue of the 15th inst., headed "Does Ozone Purify the Air?" and which, without some refutation, is liable to cause a very uneasy feeling among my Company's many clients, quite apart from the million of persons who are daily benefiting from the ventilation installations which my Company have fitted up.

The report itself, so far as facts are concerned, is not entirely inaccurate, although there are one or two serious mis-statements of fact, whilst the conclusion arrived at is evidently biassed. No doubt, the investigations were made and based on the great amount of ignorant claptrap with which the American manufacturers and sellers of Ozone apparatus have surrounded their selling literature. I have several specimens of this literature which I could place at your disposal, and you would agree that the compilers show an amount of ignorance and audacity which the medical faculty in this country accept at its face value. Nobody in his senses, and with the requisite knowledge, would be so foolish as to make such statements as the report which you print contains. The whole value of Ozone, so far as its use in ventilation is concerned, lies in its powerful oxidising effect, and the amount which it is necessary to use for the useful purification of the air is so small that no possible ill-effect can be suffered by anyone breathing such an atmosphere. On the contrary, the investigations of Dr. Leonard Hill, F.R.S., have shown that the use of ozone in this proportion—namely, one part in one million parts of air—is fraught with the greatest benefit, inasmuch as the air is freshened and smell or frowsiness is destroyed, and the result is what must be a beneficial and invigorating atmosphere. I need only draw your attention to the Central London Railway. This is used by many millions of persons per year, and the greatest testimony to its value must be the large number of employees of the Company, who are constantly working in the ozonised atmosphere, and who are most enthusiastic as to the benefits they derive. No one with any knowledge on the subject would attempt to sterilise the air of a place in which human beings were living, by means of ozone. My remarks are also confirmed by a report, which appeared in the *Times Engineering Supplement* of August 27th, on the proceedings of the Society of Heating and Ventilating Engineers of the United States, in which the remarkable air purifying effect of ozone was testified to.

The statement that ozone does not destroy bad odours is absolutely in contradiction to the practical effects of several installations which my Company have fitted up, with the sole object in view of destroying foul odours. I can cite at least one case of an installation which has been the means of putting an end to serious complaints by the inhabitants of a city, due to the nuisance arising from a certain manufacturing process.

There is no doubt whatever that Ozone does absolutely destroy bad smells and does not only mask them, and any statement to the contrary is based on insufficient practical experience.

I trust you will kindly give this letter the same prominence as that of your paragraph, and if anything were wanted to add proof to my statements, I would ask you to glance through the list of a few of the important installations of Ozone Ventilation which my Company have erected in various parts of the world, and which are contained in the enclosed pamphlet.

I am, Sir, yours truly,
Edward L. Joseph, M.I.E.E., F.C.S.,
Managing Director to
Ozonair, Limited.

London, October 20th, 1913.

[We insert the above letter, but must remind the writer that our paragraph of October 15th commented on the work of scientific experts. At its best ozone mixed with air in proportions that can be breathed with comfort cannot, from the facts of the case, be anything but a surface oxidiser. It may mask bad smells, but does it affect the chemical substances and putrefactive micro-organisms that give rise to the odours. It is difficult to imagine on what evidence our correspondent states that "there is no doubt whatever that ozone does absolutely destroy bad smells and not merely mask them?" We do not even know the physcal basis of a smell with any certainty. Emphatic assertion is not science.—Ed. M.P. and C.]

OVERTHROW OF THE VETERINARY ACT.

To the Editor of The Medical Press and Circular.

Sir,—The event which I have over and over again referred to in your columns as inevitable has now come about, and the penal clauses of the Veterinary Act have, like those of the Medical Acts and Dentists Act, been reduced to dead letters. When first placed on the Statute Book, the Veterinary Act promised to afford to dumb brutes the protection refused to the human kind by medical law. At that time, and since, I have recorded in your paper numerous instances which seemed to promise this result.

Soon after the passing of the Act an unqualified man was fined for displaying a sign inscribed "Veterinary forge." This the magistrate held to imply registration under the Act. The man did not appeal. A year or two ago, another man, unregistered, was fined for assuming the designation "Canine and feline specialist." He did not dispute the decision. A case decided in the King's Bench Division on Tuesday last shows that if those convicted under the Act in cases such as I have instanced had carried their cases to a higher court the convictions would have been quashed. In the case disposed of on Tuesday, the Glamorganshire justices had dismissed a case in which the College of Veterinary Surgeons had summoned an unregistered man who had displayed outside his premises a red lamp and a sign each inscribed "Canine surgery." The College appealed. The Judges—Ridley, Scrutton, and Bailhache—agreed in dismissing the appeal with costs. They held that the respondent had only described his premises as a canine surgery, and had not described himself as a canine surgeon. It would be interesting to learn how far the learned judges were influenced by the similar cases under the Medical and Dentists Acts, carried to the House of Lords, which have destroyed the powers of those Acts so far as these were directed to safeguarding the welfare of the public. The preamble of each of the Acts describes the penal clauses as devised to enable the public to distinguish between legally qualified and unqualified practitioners. As the Medical Acts now stand, any quack can with impunity assume the title of "Doctor," whilst the power to use the words "Dental surgery" in advertisements and on signs makes it possible for any ignorant mechanic or unscrupulous quack to palm himself off on the public as a qualified dentist. It is certain that every uneducated farrier of a certain type will avail himself of the new legal right into which he has now come, and a new field for fraudulent quackery will be opened in the veterinary department. It is possible that the Veterinary College will carry the case to the Supreme Court. But it is impossible to believe that they will meet with a better fate than the authorities who have attempted to vindicate medical law before the same august tribunal. The triumph of quackery is so far assured by law. It is certain that the army of rascaldom engaged in this cruel and nefarious trade will make the most of their opportunities.

I am Sir, yours truly,
Henry Sewill.
The Old Rosery, Earlswood Common,
October 15th, 1913.

OBITUARY.

SIR JOHN BATTY TUKE, M.D., F.R.S.E.

By the death of Sir John Batty Tuke, which took place in Edinburgh on October 13th, the medical profession in Scotland has lost one of its most conspicuous figures. Dr. Tuke was a Yorkshireman, but he had for so long been identified with Edinburgh that most of his colleagues had come to look on him as a countryman, and although he was ever proud of being a Yorkshireman his interests all lay in the land of his adoption. He was born at Beverley in 1835, but was educated at the Edinburgh Academy, and took his M.D. in Edinburgh in 1856. After graduation he served in the Maori War, and acted as Senior Medical Officer to the forces from 1860 to 1863. On his return to Scotland he determined to specialise in mental disease, and became first Assistant at the Royal Asylum, Morningside, and then Superintendent of the Fife and Kinross Asylum. In 1873 he became joint owner of Saughton Hall private Asylum, which later passed entirely under his own control, and on its passing into the hands of the Corporation some years ago the institution was transferred to another suburb of Edinburgh under the name of New Saughton. Sir John Tuke rapidly acquired the confidence of his professional brethren, not only in his own speciality, but as a councillor and leader in affairs generally. He was twice Morrison Lecturer, in 1874 and in 1894; he was President of the Psychological Section of the British Medical Association in 1895; he was President of the Neurological Society, and of the Medico-Chirurgical Society of Edinburgh. He did good work for his College as its president (1898) and as its representative on the General Medical Council from 1887 to 1912. His great claim to remembrance, however, was the part he played in organising the laboratory of the Royal College of Physicians. The proposal at one time met with much opposition, and although it would be too much to say that it owed its inception to him, without Tuke as its advocate it might never have come into existence. He ever took the deepest interest in the laboratory, and in so doing he was one of those to whom Edinburgh must always look as an ardent apostle of the importance of original research. In research and in medical education Tuke took a deep and enduring interest, and although his own contributions to medical literature were not numerous he was keenly appreciative of the advances made by others, and alive to the directions in which fresh work was required. Sir John Tuke was a D.Sc. (*hon. causâ*) of Trinity College, Dublin, and an LL.D. of his alma mater. He represented St. Andrew's and Edinburgh Universities in Parliament from 1900 to 1910, succeeding Priestly, and succeeded by Sir Robert Findlay.

Sir John Tuke was a man who wielded a great deal of influence by reason of his wide knowledge of men and affairs. He was a loyal friend and had many devoted adherents. A keen sportsman, he delighted in having his house filled with guests, to whom he played the part of the courtly, considerate host to perfection. He married a daughter of the late Rev. John Magee, Drogheda, and is survived by his widow and several children, one of whom has for a number of years been associated with him in the conduct of New Saughton Hall.

DR. MATTHEW MARTIN, OF GLASGOW.

The deceased, one of the best-known medical practitioners in the east end of Glasgow, died very suddenly on the 10th inst. Shortly after midday he became ill and dropped down at the corner of Soho Street and Gallowgate. He died before assistance could be rendered. A few minutes before he was chatting with a friend. Dr. Martin graduated at Glasgow University in 1882, and was for 30 years a member of Glasgow Parish Council. A few days before his death he was asked to become a candidate for a vacancy in the Town Council. Dr. Martin's sudden death recalls the equally sudden death, by accident, of his father, Bailie James Martin, in 1887, who was asphyxiated by a dense mass of fumes descending upon him and others from a monster blast which a municipal party had gone to witness on Loch Fyne side.

MAJOR H. C. FRENCH, R.A.M.C.

We regret to announce the death of Major Herbert Cumming French, R.A.M.C.,, which took place last week at the early age of 43. The deceased, who was the son of Major-General Sir George French, served in the South African War in the Transvaal, and in the operations in the Orange River Colony, from 1901 to 1902, and was awarded the Queen's medal with two clasps. He was a War Office Specialist on the subject of Dermatology at Cairo, 1904, Woolwich, 1905-1908, and Malta, 1909. At King's College Hospital, where he was medically educated, he had a brilliant career as a student. In 1891 he was the resident Warneford scholar, and in the following year held a senior scholarship. Major French was a silver medallist of the Royal Humane Society, and also held the Royal Albert medal. He was M.R.C.S., L.R.C.P.Lond., and had been a Hunterian Professor at the former College.

SPECIAL REPORTS.

LUNACY IN IRELAND. (*a*)

The steep ascension of the curve of incidence and the comparative ineffectiveness of all our treatment renders the lunacy problem one of the first importance. The cost of maintaining lunatics, who are almost entirely non-productive, is a heavy drain on a country where one in every 176 of the population is under care for insanity, as is the case in Ireland. The number of lunatics is steadily increasing, albeit the increase for 1912—184—is less by 77 than that of 1911, and 118 less than the average increase for the previous ten years. This crumb of comfort is far from satisfying. From 1880 to 1912 the total increase of lunatics under care has been 11,857, and this does not include the insane who reside at home or with relatives or wander at large. The only way we can estimate these is by the general census returns, and at the last one in 1911 their number is given as 1,221, which brings the Irish lunatic total for 1912 to 23,994. These figures are abundant testimony to the fundamental poverty of our knowledge of insanity. We know not, but we know that we know not; and much good work is being done in the hope that we shall finally know. At present all we can do is to see that the methods of treatment that we have found best are carried out intelligently and conscientiously.

The Report shows that in Ireland work is being well done. The reports on inspection of the different district and private asylums and lunatic wards in workhouses are favourable. Faults, of course, are found, especially in the latter class of institution, but they are of minor importance, and mostly concerned with details affecting rather the standard of comfort than the actual well-being of patients. It is agreeable to note that in the eight cases of suicide, accidental death, etc., the inspectors did not find it necessary to censure the authorities in charge.

The Report shows on the whole the lamentable weakness of our attack on insanity and the careful and conscientious manner in which we are applying such methods as seem best in the present state of our knowledge.

(*a*) "Sixty-second Annual Report of the Inspectors of Lunatics (Ireland) for the year ending December 31st, 1912." London, for H.M. Stationery Office. 1913. Price 11½d.

NEW BOOKS AND NEW EDITIONS.

The following have been received for review since the publication of our last monthly list:—

- **Bailliere, Tindall and Cox** (London).
  - Text-book on Gonorrhœa and its Complications. By Prof. Georges Luys, M.D. Translated and edited by Arthur Foerster, M.R.C.S., L.R.C.P.Lond. With 203 coloured and plain illustrations. Pp. 404. Price 15s.
  - Sleeping Sickness and the Island of Principe. By Surgeon-Captain Bernardo F. Bruto da Costa. Translated by Lieut.-Col. J. A. Wyllie, F.R.G.S. Illustrated. Pp 90. Price 2s. 6d. net.
  - Manual of Operative Surgery, with Surgical Anatomy and Surface Markings. By Duncan C. L. Fitzwilliams, M.D., Ch.M., F.R.C.S.Eng. Pp. 458. With 284 illustrations. Price 10s. 6d.
  - Sciatica, a Fresh Study. By William Bruce, LL.D., M.D. Pp. 186, with 18 plates. Price 5s.
  - Map Scheme of the Sensory Distribution of the Fifth Nerve (Trigeminus), with its Ganglia and Connections. By L. Hemington Pegler, M.D., M.R.C.S., Senior Surgeon Metropolitan Ear, Nose and Throat Hospital, etc. Printed in 15 colours and mounted on rollers for hanging up (size 4 by 5 feet), or folded in cloth cover (size 8½ by 11 inches). Price 21s. net.
  - An Introduction to the Study of Infection and Immunity. By Charles E. Simon, B.A., M.D. Second edition revised and enlarged and illustrated. Pp. 325. Price 14s. net.
- **Bale, John, Sons and Danielsson, Ltd.** (London).
  - Compendium of the Pharmacopœias and Formularies. By C. J. S. Thompson. Fourth edition. Pp. 360. Price 5s.
- **Benger and Co., Ltd.** (Manchester).
  - Alimentary Enzymes in Theory and Application. With special reference to their use in treatment and dietetics. The Benger's Food Co. With 10 photographic plates.
- **Cambridge University Press.**
  - Trachoma and its Complications in Egypt. By A. F. MacCallan, M.D., F.R.C.S. Pp. 74. Price 7s. 6d. net.
- **Chapman and Hall, Ltd.** (London).
  - Elements of Water Bacteriology. By S. C. Prescott and C. E. A. Winslow. Third edition. Rewritten Pp. 318. Price 7s 6d. net.
- **Churchill, J. and A.** (London).
  - St. Thomas's Hospital Reports. New Series. Edited by Drs. J. J. Perkins and C. A. Ballance, M.B.Lond., F.R.C.S. Pp. 230.
  - Diseases of the Rectum and Anus. By Harrison Crisp, F.R.C.S. Fourth edition. Pp. 588. Price 10s. 6d.
  - Cancer of the Rectum, its Surgical Treatment. Sixth edition. By Harrison Crisp, F.R.C.S. Pp. 256. Price 5s.
  - Transactions of the Ophthalmological Society of the United Kingdom. Vol. XXXIII. Pp. 242. Price 12s. 6d.
  - Researches on Rheumatism. By F. J. Poynton, M.D., F.R.C.P.Lond., and Alex Paine, M.D., D.P.H. With 106 illustrations, plain and coloured. Pp. 461. Price 15s.
- **King, P. S., and Son** (Westminster).
  - The Deaf. Handbook of information and statistics. Compiled by the National Bureau. Pp. 75.
- **Lewis, H. K.** (London).
  - Hæmocytes and Hæmic Affections. By F. W. G. Burnham, M.D., C.M. With 226 microphotograms. Pp. 462. Price 25s.
  - Practical Bacteriology, Blood Work and Animal Parasitology. B. G. R. Stitt, A.B., Ph.G., M.D., U.S.A. Third edition, with 4 plates and 106 other illustrations. Price 6s. 6d.
  - Lectures on Tuberculosis to Nurses. By Oliver Bruce, M.R.C.S., L.R.C.P. Illustrated. Pp. 134. Price 2s. 6d. net.
  - Manual of Operative Surgery. By J. F. Binnie, A.M., C.M.Aber. Sixth edition revised and enlarged and illustrated. Pp. 1251. Price 30s. net.
- **Lippincott, J. B., Co.** (Philadelphia).
  - Treatment of Internal Diseases. By Prof. Norbert Ortner. Translated by F. H. Bartlett, M.D. Second edition in English. Edited by N. B. Potter, M.D., New York. Pp. 643. Price 21s.
  - The Psychoneuroses and their Treatment by Psychotherapy. By Drs. J. Dejerine and E. Gauckler. Translated by Smith E. Jelliffe, M.D., Ph.D. Pp. 396. Price 18s.
- **Longmans, Green and Co.** (London).
  - Gray's Anatomy. Eighteenth edition. Edited by Prof. Robt. Howden, D.Sc., C.M. Assisted by A. J. Jex-Blake, B.Ch., F.R.C.P., and W. F. Fedden, M.S., F.R.C.S. Pp. 1311. With 1,120 illustrations, plain and coloured. Price 32s.
  - The National University of Ireland. Calendar for the year 1913. Pp. 480.
- **Macmillan and Co.** (London).
  - The Nervous and Chemical Regulators of Metabolism. Lectures by Prof. D. Noel Paton, M.D., B.Sc. Pp 228. Price 6s.
- **Rebman and Co., Ltd.** (London).
  - Compendium of Regional Diagnosis in Affections of the Brain and Spinal Cord. By Robt. Bing. Translated by F. S. Arnold, M.B., B.Ch. Second edition. Pp. 222.
  - An International System of Ophthalmic Practice. By W. L. Pyle, M.B., Philadelphia. Ophthalmic Seismology by C. H. Beard, M.D. Pp. 400. Price 21s.
  - Therapeutics of the Gastro-Intestinal Tract. By Drs. Carl Wegele, M. H. Gross and I. W. Held Pp. 329. Price 12s. 6d.
  - A Course of Normal Histology. By Rudolf Krause. Translated by P. J. R. Schmahl, M.D., New York. Pp. 406. Price 25s.
- **Reeves, William** (London).
  - The Art of Vocal Expression. A Popular Handbook. By Rev. Chas. Gibb. Pp. 91.
- **Saunders, W. B., Co.** (Philadelphia).
  - Collected Papers by the Staff of St. Mary's Hospital Mayo Clinic, Rochester, U.S.A. 1912. Pp. 842.
  - Massage, its Principles and Technic. By Max Bohm, M.D. Translated by C. F. Painter, M.D., Boston. Pp. 91. Illustrated.
  - The Elements of Bacteriological Technique. By J. W. H. Eyre, M.D. Pp. 518, with 219 illustrations. Price 13s.
  - A Laboratory Manual of Invertebrate Zoology. By G. A. Drew, M.D. Second edition. Pp. 213.
  - Blood Pressure from the Clinical Standpoint. By Francis Ashley Faught, M.D. Illustrated. Pp. 281. Price 13s. net.
- **Taylor and Francis** (London).
  - Calendar of the Royal College of Surgeons of England. August 1st, 1913. Pp. 398. Price 1s.
- **The Ophthalmoscope Press** (London).
  - Guide to the Microscopic Examination of the Eye. By Prof. Greeff, Berlin. Translated by Hugh Walker, M.B., C.M. Pp. 86. Price 7s. 6d.
- **Truth Publishing Co., Ltd.** (London).
  - Minor Statesmen from Truth. Pp. 151. Price 1s.
- **Unwin, T. Fisher** (London).
  - Lord Lister, his Life and Work. B. G. T. Wrench, M.D.Lond. Pp. 384. Price 15s.
- **Urban and Schwarzenberg** (Berlin).
  - Pathologisch-Anatomisches Praktikron. Von Prof. Dr. Richard Oestreich. Pp. 304.
- **Wright, John, and Sons, Ltd.** (Bristol).
  - Pye's Elementary Bandaging. Thirteenth edition. Revised by W. H. Clayton-Greene, M.B., F.R.C.S., and V. Zachary Cope, M.D., F.R.C.S. Pp. 230. Price 2s.
  - A Synopsis of Midwifery. By A. W. Bourne, M.B., F.R.C.S. Pp. 212. Price 5s.

LITERARY NOTES.

We understand that Professor Dawson Turner, of Edinburgh, has a new edition in the press of his work on "Radium, its Physics and Therapeutics," which will embody the most recent researches on the subject. The author is an acknowledged authority, having made radium his especial study; his researches and views on the subject now so much to the fore, will be looked for with considerable interest.

* * *

The "Calendar" for 1913 of the National University of Ireland reaches us seasonably with the beginning of the winter session. The text of the Irish Universities Act, 1908, and the University Charter are printed in full. The usual information as to courses of study and examinations is given. Lists of names include not only the officials and graduates of the University, but also the officers of its three constituent colleges.

* * *

Our contemporary, the "Indian Medical Record," announces that in consideration of the prevalence and mortality of tuberculosis in India, and that it is making rapid progress in that country, it has been decided to make a special issue of that journal as a "Tuberculosis Number." This special issue will contain valuable contributions from the pen of those who have devoted much time in the investigation of this disease. The Editor will also be glad to receive any articles or short notes on the subject bearing on its prevention and treatment based on personal experience from medical men for publication in this number, which should reach the office (Calcutta, India) by the middle of November, 1913.

* * *

We are asked to announce that the next award of the Alvarenga Prize by the College of Physicians of Philadelphia, amounting to about 180 dollars, will be made on July 14th, 1914, provided that an Essay deemed by the Committee of Award to be worthy of the prize shall have been offered. Essays intended for competition may be upon any subject in medicine not previously published. They must be typewritten, and if in a language other than English, should be accompanied by an English translation, and must be received by the Secretary of the College on or before May 1st, 1914. Each essay must be sent without signature, but must be plainly marked with a motto and be accompanied by a sealed envelope having on its outside the motto of the paper and within the name and address of the author.

NEW PREPARATIONS.

"TABLOID" ADJUSTABLE HEAD DRESSING.

As a means of fixing dressings on the head, the "Tabloid" Adjustable Head Dressing of Burroughs Wellcome and Co., which is now issued in a large size, deserves the notice of all medical practitioners. It consists of a cap, split at one side to render it adjustable, and having a back-piece covering the nape of the neck. To the cap a bandage is attached, while the back-piece carries tapes. A pad of double cyanide gauze and a safety pin are enclosed with the head dressing for use in first-aid cases. It is applied by slipping the cap over the head and passing the bandage portion round the back of the head, across the forehead, and back again to the starting point, where is is fixed with a safety pin. The tapes attached to the back-piece are tied under the chin, so allowing the bulky dressings to be covered in and secured. For use in operations on the eye, ear, nose and throat the adjustable head dressing affords great advantages over a towel, which is insecure and uncomfortable for the patient and, from its bulk, apt to get in the way of the surgeon and to be displaced. It also affords a ready means of covering the head in the treatment of ringworm, favus, impetiginous conditions of the scalp, and so forth. Numerous applications will readily occur to anyone using it.

BAYER'S HYDRASTININE (SYNTHETIC). HÆMOSTATIC.

While the hæmostatic value in gynæcological practice of the rhizome of hydrastis canadensis is well established, the ordinary galenical preparations are unsatisfactory, being unpleasant in taste and uncertain in composition. The active principle of the rhizome is the alkaloid hydrast*ine*, and from this alkaloid may again be prepared by an oxidation process hydrast*inine*, which provides not only a means of *standardised* hydrastis treatment, but removes from such treatment certain disadvantages. Messrs. Bayers have found it possible to prepare hydrastinine synthetically, the artificial product being identical both as to composition and therapeutic action with that obtained from the rhizome. Synthetic hydrastinine hydrochloride is a white powder, soluble (1 in 1) in cold water.

For hydrastinine is claimed the advantages over hydrastine that its action as a hæmostatic (and especially a uterine hæmostatic) is more powerful and lasting, that it has no depressant action on the heart, and that it does not cause tetanic spasms. Its action may be briefly epitomised thus:—(1) It stimulates the medulla; (2) it causes a powerful contraction of the peripheral vessels; (3) it causes contraction of the uterine muscle; (4) it is a useful stomachic and tonic. It is also worthy of note that hydrastinine hydrochloride acts immediately, while other preparations of hydrastis require several days before producing any effect. It is supplied by Messrs. Bayer in bottles of ½ and 1 gramme.

MEDICAL NEWS IN BRIEF.

Society for Relief of Widows and Orphans of Medical Men.

At a quarterly Court of the Directors of this Society held on Wednesday, Sir Thomas Boor Crosby, President, in the chair, twenty new members were elected. The sum of £523 was voted to be distributed among th widows and orphans at Christmas, each widow to receive £10, each orphan £3, and each orphan on the Copeland Fund £10. It was resolved that the income from the Brickwell legacy be utilised as follows:—

(1) That the legacy received from the late Mr. James Brickwell be known as the "Brickwell" Fund, and any grant made from it be marked as coming from that fund.

(2) That the grants to widows over the age of 65 may be increased by £25 per annum.

(2a) That the grants to widows under the age of 65 may be increased by £10 per annum.

(3) That the grants under the Copeland Fund may be increased from the Brickwell Fund by £20 per annum.

(4) That an increased grant of £15 per annum may be made to the orphans, other than those in receipt of grants under the Copeland Fund.

(5) That the residue of income be kept on deposit and utilised as directed by the Court of Directors.

The total amount of the Brickwell legacy is £37,250, yielding an annual income of £1,325 10s. The invested funds of the Society now stand at £139,500. Relief is only granted to the widows and orphans of deceased members. Membership is open to any registered medical practitioner who at the time of his election is resident within a radius of 20 miles of Charing Cross. The annual subscription is two guineas; special terms for life membership. Further particulars and application form for membership may be obtained from the Secretary at the Offices of the Society, 11 Chandos Street, London, W.

Electrolysis in Lead Poisoning

At a provincial sessional meeting of the Royal Sanitary Institute at Newcastle-on-Tyne on Saturday last, Mr. T. M. Clague gave a demonstration of his system of treating cases of industrial lead poisoning by electrolysis, and furnished an account of the successful tests made by Sir Thomas Oliver, M.D. Experiments had demonstrated that metal poisons were removed from the human body by electric baths, applications being made to the feet, arms, and other parts of the body.

Professor Sir Thomas Oliver, M.D., said a weekly hot-water bath for lead workers was required by the Home Office, and he suggested the substitution of the electrolytic bath. He stated that, under this treatment, the blue line in the gums, which was a characteristic indication of lead poisoning, disappeared.

An American Ward in the London Hospital.

It is reported that a fund has been started, known as the American Ward London Hospital Fund, the object of which is to endow a ward in the London Hospital for Americans, to be supported by Americans. Among those who have become patrons and subscribers are Lady Barran, Mrs. Otto Beit, Lady Arthur Butler, the Hon. Mrs. C. Coventry, Lady Randolph Churchill, Mrs. Anthony J. Drexel, the Countess of Essex, Lady Alastair Innes-Ker, Mrs. Rudyard Kipling, the Hon. Mrs. R. C. Lindsay, Viscountess Maidstone, Lady Maxim, Lady Maxwell, Lady Naylor-Leyland, Lady Malcolm of Poltalloch, and Mrs. M. F. Ronalds.

The Norfolk and Norwich Hospital.

The Lord Mayor of Norwich (Mr. Arthur M. Samuel) presented at a meeting of the Governors of the Norfolk and Norwich Hospital, last week, a cheque for £2,500 in liquidation of the accumulated deficiencies in the funds of the hospital, which in December last amounted to £5,040. This was in fulfilment of a promise the Lord Mayor made last June, the condition being that other friends of the hospital would contribute an equal sum before the expiration of his year of office.. This met with a liberal response, £2,700 having been subscribed within a few days of Mr. Samuels' offer.

University College Hospital.

The treasurer has received from a donor, who wishes to remain anonymous, the sum of 100 guineas as an expression of his admiration and appreciation, from personal observation, of the skill, invariable kindness, and admirable nursing accorded to the patients at University College Hospital.

Haslar Royal Hospital.

The distribution of prizes to the acting surgeons on the completion of their course at the Royal Hospital, Haslar, took place last week in the library of the institution. The presentations were made by Adm. the Hon. Sir Hedworth Meux, Commander-in-Chief at Portsmouth. Acting-surgeon A. M. Henry, of Guy's Hospital, was awarded the gold medal for the best total of marks obtained on entry at Greenwich and Haslar, and also a prize for the highest marks at the Greenwich Examination. Acting-surgeon G. F. B. Page, Edinburgh University, took the silver medal. Commissions as surgeons in the Royal Navy were afterwards handed to 14 officers.

Sir Jonathan Hutchinson's Museum.

At a meeting held at Haslemere last week a subcommittee was appointed to prepare a scheme for the future maintenance of the Haslemere Educational Museum, founded by the late Sir Jonathan Hutchinson. It is hoped that their report will be presented at a future meeting, which will probably be public.

Mr. Aneurin Williams presided, and it was announced that Mr. Jonathan Hutchinson, writing on behalf of the trustees of the late Sir Jonathan Hutchinson's estate, had stated that if it were found possible to raise the necessary endowment fund, the trustees were willing to hand over by deed the freehold site and the museum with all its contents to a suitable trust committee. It was also intimated that other members of the Hutchinson family were prepared to give substantial monetary help to any fund which it might be proposed to raise. The value of the site is estimated by the trustees at about £4,000, and the money spent by the founder upon the buiding and the collection was probably upwards of £20,000. The trustees are willing to maintain the museum for another 12 months in order to give the committee time to deal with the situation.

In a letter regretting his inability to be present Sir Archibald Geikie (President of the Royal Society), wrote:—"For the quiet but helpful teaching which the museum has afforded to thousands of learners every year for so long a time we are under a debt of sincere gratitude to the liberal mind and generous public spirit of its illustrous founder, and we owe it to Sir Jonathan Hutchinson's memory to ensure that the institution which he created, and for so many years supported at his own cost, should not suffer by his death, but be continued and maintained in full efficiency.

Society of Medical Officers of Health.

The annual dinner of the Society of Medical Officers of Health was held last week at the Hotel Great Central, Dr. A. K. Chalmers, president, occupying the chair. Among those present were Sir Francis Champneys (president of the Royal Society of Medicine), Sir Thomas Barlow (president of the Royal College of Physicians), Sir Amherst Selby-Bigge, Dr. A. Newsholme, Surgeon-General Baptie, V.C., Sir Shirley Murphy, Dr. Harmer, Baillie E. McConnell (convener of the Committee on Health, Glasgow Corporation), and Professor Sims Woodhead.

Nominations for Edinburgh Chair of Clinical Medicine.

In accordance with the new arrangement come to between the University of Edinburgh and the Royal Infirmary, it falls to a Joint Committee of seven members from the University Court and the Royal Infirmary to make nominations to the Court for the new Moncrieff Arnott Chair of Clinical Medicine. At a meeting of the Joint Committee held on Saturday, Dr. William Russell and Dr. Graham Brown were selected from a list of applicants for the Professorship, and the names of these gentlemen will be submitted to the University Court, which will meet on the 20th of this month, to make the appointment. Drs. Russell and Brown are both associated with the Royal Infirmary, and act as senior lecturers on Clinical Medicine in the University.

Royal Sanitary Institute.

The following medical members have been elected during October:—Andrew Balfour, M.D., B.Sc.Ed., D.P.H.Camb., Edward A. Brash, L.R.C.P.Lond., M.R.C.S.Eng. (M.O.H.), Thos Buckham, M.B., B.S. (M.O.H.), L. T. Burra, M.B., B.Ch.Oxon., M.R.C.S., Robert V. Clark, M.A., M.B., B.Sc.Ed., D.P.H., James A. Dalmege, M.R.C.S.Eng., L.R.C.P., D.P.H. Lond., Thomas E. Francis, D.P.H.Lond., Herbert E. Goulden, M.D.Durh., D.P.H.Camb., John Lambie, M.D., D.P.H., Alex. R. M. MacIlraith, L.R.C.P., L.R.C.S.Ed., Stewart McNaughton, M.B., D.P.H. Camb., Shobba Ram, M.B., B.A., D.P.H.Lond., Alex. W. F. Sayres, M.D., M.R.C.S., D.P.H., Percy H Stirk, M.R.C.S., D.P.H., Reginald W. Stocks, L.R.C.P., M.R.C.S., D.P.H., George B. Wray, M.R.C.S.Eng., D.P.H.Lond.

Prevention of Infant Mortality.

A second Post-Graduate Course on the Feeding and Care of Infants will be held from January 12th to January 22nd, 1914, under the auspices of the National Association for the Prevention of Infant Mortality and for the Welfare of Infancy. A strong Advisory Committee has already been formed, the members including Sir Thomas Barlow, Dr. W. Hale White, Dr. E. W. Hope, Dr. James Kerr, Professor C. J. Martin, Sir Shirley Murphy, Dr. Arthur Newsholme, Sir William Osler, Sir John Tweedy and others. This Course will be on the same lines as those which proved so successful in the first, but there will, in addition, be an evening lecture each day. A full syllabus and further particulars will be obtainable shortly from the Secretary of the Association at 4, Tavistock Square, London, W.C.

Sleeping Sickness Inquiry Opened.

The Departmental Committee on African Diseases began its inquiries recently at Winchester House, London. The Committee, of which the Earl of Dysart is chairman, is asked by the Government to report upon (1) the present knowledge available on the questions of the parts played by wild animals and tse-tse flies in Africa in the maintenance and spread of trypanosome infections of man and stock, (2) whether it is necessary and feasible to carry out an experiment of game destruction in a localised area in order to gain further knowledge on these questions, and, if so, to decide the locality, probable cost, and other details of such an experiment, and to provide a scheme for its conduct, (3) whether it is advisable to attempt the extermination of wild animals, either generally or locally, with a view of checking the trypanosome diseases of man and stock, and (4) whether any other measure should be taken in order to obtain means of controlling these diseases. The first witness was Surgeon-General Sir David Bruce, who has been in charge of the Royal Society's Sleeping Sickness Commission in Nyassaland. The inquiry was not open to the Press.

University of Oxford.

At a congregation held on October 16th, the following degrees were conferred:—

D.M.—A. T. Waterhouse, Balliol; G. D. H. Carpenter, Non-Collegiate.

B.M.—G. W. Carte, New College.

University of Cambridge.

At a congregation held on October 17th, the following degrees were conferred:—

M.D.—C. B. Heald and G. W. Twigg, Caius; K. Comyn (by proxy), Selwyn.

M.B. and B.C.—R. Gamlin and A. E. Herman, King's; A. C. Roxburgh, Trinity; L. W. K. Scargill, Trinity Hall; G. A. Smythe, Emmanuel.

M.B.—C. C. H. Binns, Caius; L. T. Rutherford (by proxy), Clare; T. E. Osmond, Emmanuel .

B.C.—R. S. Morshead, Trinity.

Royal College of Surgeons of Edinburgh.

The following candidates having passed the requisite examinations, on July 12th, 1913, were admitted Fellows on Thursday, October 16th:—Henry E. Arbuckle, M.D.Ed., D.P.H.Camb., James F. Bennett, M.B., Ch.B.Glasg., John D. Fiddes, M.B., Ch.B. Aberd., Percy L. Foote, M.B., Ch.B.N.Zeal., M.R.C.S., L.R.C.P., McWilliams Henry, L.R.C.S.E. (triple qual.), Harry F. Holmden, M.B., Ch.B.Ed., Harris C. Mersereau, M.D., C.M.McGill, John J. H. Nelson, M.D.Edin., Adreshir B. Pestonji, L.M. and S.Bombay, M.R.C.S.Eng., L.R.C.P., D.P.H.Camb., Richard F. Steel, M.B., Ch.B.Dub., Howard M. B. Stratford, M.R.C.S.Eng., L.R.C.P., Arthur R. Thomas, M.R.C.S.Eng., L.R.C.P., Stephen H. Middleton-West, M.B., Ch.B.Vict.Univ.Man., M.R.C.S. Eng., L.R.C.P., and Hiram B. Wyman, M.D., C.M. McGill, L.R.C.S.E. (triple qual.).

A case of some importance to medical practitioners—namely, that of "spotted fever," was recently notified to the Metropolitan Asylums Board from Camberwell (London), and the patient was removed to the South-Eastern Fever Hospital. This is the third notification of this disease to the Board within the past week or two.

NOTICES TO CORRESPONDENTS, &c.

☛ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

M.B.CANTAB. (London, N.).—The influence of menstruation upon the temperature of the body is well known. Recent observations by Hansen show that menstruation brings a temperature wave rising high just before the menses and falling below the normal afterwards, beginning to rise again about a fortnight before the date of the next menstrual epoch.

F. E. R. (Norfolk).—Most byelaws dealing with the construction, etc., of ashpits provide that they shall not exceed three cubic feet in size—i.e., sufficient for one week's refuse. It is imperative that a tightly-fitting cover be fixed, and it should be elevated at least 9 in. above the ground. No ashpit should be placed so that its contents are inaccessible to easy inspection and removal.

DR. J. H. (Somerset).—A good foot powder, which may be sprinkled within the socks in cases of hyperidrosis, is salicylic acid, 1 part; rice powder, 10 parts; talc 40 parts.

Meetings of the Societies, Lectures, &c

WEDNESDAY, OCTOBER 22ND.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—5.30 p.m.: Mr. Colyer.

THURSDAY, OCTOBER 23RD.

ROYAL SOCIETY OF MEDICINE (SECTION OF BALNEOLOGY AND CLIMATOLOGY) (1 Wimpole Street, W.).—5.30 p.m.: Presidential Address: Dr. F. A. de T. Mouillot: Some Lessons derived from Twenty Years of Spa Practice. The Annual Dinner will be held at 7.15 p.m., the same evening at the Waldorf Hotel, and the following are expected as guests of the Section:—Sir Malcolm Morris, Sir Philip Magnus, and Dr. A. Manuel.

FRIDAY, OCTOBER 24TH.

ROYAL SOCIETY OF MEDICINE (SECTION FOR THE STUDY OF DISEASE IN CHILDREN) (1 Wimpole Street, W.).—4.30 p.m.: Cases by Dr. C. E. Zundel, Dr. E. A. Cockayne, Dr. J. Porter Parkinson, Dr. T. R. Whipham, Dr. F. Langmead. Pathological Specimens: Dr. J. Porter Parkinson, Dr. J. D. Rolleston.

ROYAL SOCIETY OF MEDICINE (SECTION OF EPIDEMIOLOGY AND STATE MEDICINE) (1 Wimpole Street, W.).—8.30 p.m.: Paper: Dr. W. M. C. Wanklyn: Working-class Home Conditions in London.

ROYAL COLLEGE OF SURGEONS OF ENGLAND (Lincoln's Inn Fields, W.C.).—5 p.m.: Prof. Keith.

MONDAY, OCTOBER 27TH.

MEDICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—8.30 p.m.: Discussion on "The Visceral Complications met with in Hysterectomy for Fibroids and the best Method of Dealing with Them," to be introduced by Sir John Bland-Sutton.

ROYAL SOCIETY OF MEDICINE (SECTION OF ODONTOLOGY).—8 p.m.: President's Introductory Address by Mr. C. F. Rilot. Paper: Mr. Stanley P. Mummery: The Conservative Treatment of the Pulp.

TUESDAY, OCTOBER 28TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF MEDICINE).—5.30 p.m.: Sir William Osler, Bart., F.R.S.: Congenital Syphilis of the Liver, with the picture of Banti's Disease. Dr. Poynton, Dr. Armstrong and Dr. Nabarro on Chronic Recurrent Diarrhœa in Childhood. Dr. Gossage and Dr. Braxton Hicks: Two Cases of Non-Cancerous Tumour of the Stomach.

ROYAL SOCIETY OF MEDICINE (SECTION OF PSYCHIATRY).—8.15 p.m.: Demonstration: Dr. J. W. E. Cole: Case of Pellagra with Insanity. 8.30 p.m.: Paper: Dr. Mercier: What is Insanity?

BRITISH OTO-LARYNGOLOGICAL SOCIETY.

WE are asked to announce that a Clinical Meeting of the Society will take place on Wednesday, October 29th, at 4 p.m., at 11 Chandos Street, Cavendish Square, W.

Appointments.

BROCKMAN, R. ST. L., M.R.C.S., L.R.C.P.Lond., Senior House Surgeon at St. Bartholomew's Hospital.

CARTE, G. W., M.R.C.S., L.R.C.P.Lond., Senior House Surgeon at St. Bartholomew's Hospital.

DOLAN, E. M., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory and Workshop Acts for the Wigton District of the county of Cumberland.

EVANS, A. G., M.R.C.S., L.R.C.P.Lond., Senior House Physician at St. Bartholomew's Hospital

FIDDIAN, J. V., M.R.C.S., L.R.C.P.Lond., Senior House Surgeon at St. Bartholomew's Hospital.

HADFIELD, G., M.B., B.S.Lond., Senior House Physician at St. Bartholomew's Hospital.

KITCHING, R. L., M.B., B.S.Durh., Ophthalmic House Surgeon at St. Bartholomew's Hospital.

Vacancies.

National Maternity Hospital, Dublin.—Intern Assistant Physician. Salary £50 per annum. Applications to Secretary. (See advt.)

Certifying Factory Surgeon.—The Chief Inspector of Factories announces the following vacant appointment:—Chatteris (Cambridgeshire).

Oxford County Asylum, Littlemore, near Oxford.—Assistant Medical Officer. Salary £150 per annum, with apartments, board, and washing. Applications to the Medical Superintendent.

The Manchester Northern Hospital for Women and Children, Park Place, Cheetham Hill Road.—Junior House Surgeon. Salary £100 per annum, with apartments and board. Applications to Mr. Hubert Teague, Secretary, 38 Barton Arcade, Manchester.

West Herts Hospital, Hemel Hempstead, Herts.—Resident Medical Officer. Salary £100 per annum, with rooms, board, and washing. Applications to Robt. L. Butterfield, Clerk to the Hospital.

Lancashire County Asylum, Winwick, Warrington.—Assistant Medical Officer. Salary £200 per annum, with board, furnished apartments, attendance, and washing. Applications to the Medical Superintendent.

Glasgow District Mental Hospital.—Junior Medical Officer. Salary £150 per annum, with board, lodging, and laundry. Applications to the Medical Superintendent, Gartloch, Gartcosh.

Glasgow District Mental Hospital, Lenzie.—Junior Assistant Medical Officer. Salary £150 per annum, with board, lodging, and laundry. Applications to the Medical Superintendent.

Births.

CORBETT.—On October 17th, at 28 Hanover House, Regent's Park, the wife of Dudley Corbett, M.D., of twin daughters.

COX.—On October 19th, at Bannu, North-west Frontier Province, India, to Dr. and Mrs. R. J. H. Cox, C.M.S.—a daughter.

PEARCE.—On October 16th, the wife of John L. Pearce, M.D., Finchingfield, Essex, of a daughter.

Marriages.

ADAMS—WEBB.—On October 14th, at St. Nicholas Church, Chislehurst, Joseph E. Adams, M.S., F.R.C.S., of 40 Devonshire Place, W., to Muriel, youngest daughter of the late Harry Webb and Mrs. Webb, of Southlaund, Chislehurst.

CHURCH—SOMERVILLE.—On October 14th, at St. Andrew's, Wells Street, W., Geoffrey Selby, younger son of Sir William Selby Church, Bt., of Woodside Place, Hatfield, Herts, to Doris Louise Cleghorn, younger daughter of Dr. William Somerville, Fellow of St. John's College, Oxford.

EDWARDS—STANTON.—On October 15th, at Christ Church, Cheltenham, Hugh Anderson Edwards, M.B., Ch.B., Wallsend-on-Tyne, and son of the late Joseph Edwards, Motherwell, Scotland, to Illma Irene Stanton, youngest daughter of the late Alfred Alexander Stanton, of Johannesburg.

PAINTON—EVEN.—On October 15th, at the Church of St. Mary-at-the-Walls, Colchester, Capt. George R. Painton, R.A.M.C., son of G. H. Painton, Esq., Sidcup, Kent, to Aileen Mona, daughter of Colonel G. E. Even, C.B. (Indian Army), and Mrs. Even, of 34 Inglis Road, Colchester.

RIDGE—BAKER.—On October 7th, at Christ Church, Enfield, Middlesex, Edwyn Manners Ridge, F.R.C.S., of New River House, Enfield, fifth son of the late J. James Ridge, M.D., to Gladys Boyne, younger daughter of W. H. Baker, of Bush Hill Park, Enfield.

SCHUTZE—MENDL.—On October 18th, at the Registry Office, St. Marylebone, Harrie Hugo Leslie Schutze, M.D., M.B., younger son of John Schutze, of Hamburg and Melbourne, to Gladys Mendl, only daughter of Mrs. Arthur L. Raphael, of 2 Hanover Terrace, Regent's Park.

Deaths.

ADAM.—On October 19th, at Dingwall, Ross-shire, Scotland, suddenly, John Adam, M.D.

ANGUS.—On October 18th, at his residence, Thornleigh, Bentinck Road, Newcastle-on-Tyne, suddenly, James Acworth Angus, M.R.C.S., L.S.A., in his 78th year.

CARPENTER.—On October 15th, at Wykeham House, Bedford Park, Croydon, Arthur Bristowe Carpenter, M.A., M.B.Oxon., L.R.C.P.Lond., M.R.C.S., in his 60th year.

HAIGH.—On October 13th, at East View, Milnsbridge, Yorks, John William Haigh, L.S.A., aged 43.

KENNEDY.—On October 14th, at 96 Addison Road, Kensington, W., Dr. Samuel Kennedy, aged 85.

MARTIN.—On October 10th, suddenly, at Glasgow, Matthew Martin, M.B., C.M.Glasg., of "Glencairn," Tollcross Road, Glasgow.

SWALLOW.—On October 11th, at Clifton Lodge, Clarence Road, Clapham Park, S.W., James Dodd Swallow, M.D.St. And., M.R.C.S.Eng., L.S.A.Lond., in his 78th year.

WRIGHT.—On October 19th (as the result of an accident), at a private nursing home, Dublin, Edward R. M. Wright, eldest son of Sir Almroth Wright, of 6 Park Crescent, London, and grandson of R. M. Wilson, Esq., of Coolcarrigan, in his 24th year.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVII. WEDNESDAY, OCTOBER 29, 1913. NO. 18.

NOTES AND COMMENTS.

The World's Tuberculosis Campaign.

THE closing of the International Tuberculosis Congress at Berlin suggests a hope that the nations of the world will one day abandon war amongst themselves and turn their combined forces against such common foes as disease and poverty and other enemies of moral, physical and social progress. It is comforting to find that the world is slowly but surely making headway against the malady. In view of the fact that the specific organism was discovered by Koch only in 1880, the fact that the disease has been materially diminished in 1913 points to a result that may be described in terms of public health as rapid beyond precedent. Much remains to be learnt as to the preventive and the curative aspects of tuberculosis. The use of tuberculin as a remedy is still surrounded with obscurity, and in spite of the enormous amount of work that has been undertaken, there is no generally established system of dosage, and no accepted standardising and therapeutic differentiation of the many varieties of the drug. Prevention in the United Kingdom is in a similar vague and tentative stage of evolution. No strong grip has yet been secured by the State of the tuberculous cows which are almost certainly the cause of a vast amount of tuberculosis, especially in infants. Nor is the control of tuberculous meat of the universal and stringent kind absolutely essential for any system of scientific prevention. Much has been gained, however, in the mere fact that these measures have engaged the serious attention of politicians, especially when one realises the vast interests likely to be penalised by preventive legislation.

Notification.

ANOTHER vexed question in prevention is that of notification, the principle of which has only been recently endorsed by the State. What hope can there be in half measures in dealing with so universal and insidious an infection as that of tuberculosis? Why should we enforce notification in the case of scarlet fever and small-pox, but not in consumption? Why, so far as that goes, should we neglect compulsory notification of measles, whooping-cough, and syphilis, all specific infectious diseases deadly in their nature and preventable in their incidence? The only answer that occurs to one is that the whole system of preventive medicine is yet in its comparatively early stages of development, and that as the result of a series of compromises and of hastened or retarded progress, its present administration is little more than a tangled mass of inconsistencies. The Berlin Congress has dealt with various important details in the tuberculosis campaign. It is proposed to hold an International Tuberculosis Day to be observed by all the nations. A common plan of recording the results of sun treatment and a special investigation of tuberculosis amongst teachers were adopted. A uniform method of pulmonary examination was also recommended. The President, Dr. Bumm, in closing the Congress, announced that the next meeting would take place at Christiania in 1915.

A "New Medical Specific."

THE *County and City of London Observer* of October 18th contains a notice of "a new medical specific." It states that a clinical investigation has lately been carried out on patients in London hospitals. The specific is stated to raise the blood decimal to two degrees above normal. Its composition is described as a combination of natural salts, "certain of which are in a concentrated form, producing a powerful beneficial action upon the blood." The interesting information is appended that this new therapeutic agent has been tested in hospital at the instance of Mr. David Doig, of New Bond Street, chief of the well-known firm of His Majesty's publishers, who supplied the formula of the specific, which had been known and tried by him for many years. It would be interesting to learn what are this gentleman's qualifications for so highly skilled a clinical study as the effect of any given drug or combination of drugs upon the blood. It would be still more interesting to learn upon what conditions a physician has been induced to carry out the series of experiments upon hospital patients, upon the strength of whose report upon the "new medical specific" the *Observer's* notice is based. Apparently Mr. Doig is acting in good faith, for it is stated that, in view of the importance of the result, a copy of the report will be sent on application to him to medical practitioners, members of health committees and others interested. The outcome of this lay incursion into a complex branch of the art of healing may be looked for with some amount of curiosity. Unfortunately, the precise way in which the remedy is to be placed on the market is not mentioned. It is to be hoped that the "physician" and the "hospital" have not been led into a false position, as scientific medical investigations are not usually announced thus by lay newspapers.

The Suffragette Progress.

SEVERAL things of interest have happened in connection with the militant suffragettes during the past few days. In London the raid on the Harley Street windows has been followed by the patrolling of the district by sandwichwomen bearing protests against forcible feeding. Other misguided females have been ostentatiously entering in note-books the names on the brass plates from door to door. When the vigilance of the police becomes somewhat relaxed it may be their intention to smash a few more score pounds' worth of glass—which is not likely to help their cause other than on the downward path. In America, Mrs. Pankhurst—the arch-militant, so to speak, of this ill-balanced crew—has been refused admittance to the country—like Miss Marie Lloyd—as an undesirable alien. On appeal it is reported later that she has been permitted to remain on condition that she does not preach her doctrines. Last week at Bristol reprisals were the order of the day amongst the University undergraduates. Their sports pavilion had been burnt down by the local members of the criminal conspiracy known as the militant section of the suffragettes. In retaliation the students ransacked the suffragette premises and burnt their contents in a street bonfire. It seems tolerably safe to predict that if the patience of the public is taxed much further the desire for vengeance will not be satisfied by the mere burning of a few chairs and bundles of pamphlets. Mr. Lloyd George, who is a firm supporter of the female franchise, pointed out, in a recent speech, the incalculable harm the campaign of violence had brought upon the cause. For one thing, it had destroyed any hope of favourable legislation by the present Parliament. We should imagine the hostility aroused by this orgy of criminal spitefulness will probably outlast the present generation.

A Misfortune to the National Anti-Vivisectionists. Despite our grave and utter disapproval of the anti-vivisectionist views and methods of the Hon. Stephen Coleridge it is impossible to withhold our sympathy over the misfortune that has recently overtaken the affairs of the organisation for which he has toiled so long and so wholeheartedly. Briefly, the National Anti-Vivisection Society has been robbed by its trusted Secretary, Mr. Lionel J. Arbuthnot, of the sum of £6,000. The methods adopted by the defaulter are not unfamiliar. The Society had two banking accounts, and by clever manipulation of these, aided by a Machiavellian use of Mr. Coleridge's friendliness, the money came into the Secretary's possession. The downfall of the official is ascribed, according to one account, to habits of gaming and betting. The amount of the deficit, if we remember aright, bears a close resemblance to the sum collected to defray the damages and costs incurred in the notorious Lind-af-Hageby libel action. It will be of some interest to note with what amount of clemency the Society will regard this criminal action of their official. To be tender-hearted even to the most exquisite pitch in the case of mice, guinea-pigs, pigeons, and other lower animals, does not, in our experience, in any way connote a gentle charity for the peccadilloes of a mere fellow man or woman mammal, no matter how tempted, erring or unfortunate the sinner might have been.

LEADING ARTICLES.

THE FALLING BIRTH-RATE.

The steady fall of the birth-rate that of late years has been more or less universal amongst the civilised races of the Western world presents problems of weighty importance to mankind. It is a mere question of arithmetic in certain instances to say how long a given nation will survive a continuance of diminution at the present rate. The central fact that has to be faced by politicians, by moralists, by religious teachers, by economists, by sociologists, by biologists, and medical men generally, as well as all others interested in this subject, is that women all over the world are declining to bring forth children to the full extent of that maternal fruitfulness with which they have been endowed by nature. The revolt, in a word, is one of women. The results are far reaching in many directions. The position of women in the matter is twofold; first, from the point of view of the mother herself, and, secondly, that of the children. There can be no doubt that the bearing of a large family tends to shorten the life of the individual woman, both by the accidents of actual gestation and the added burdens of maternal and domestic anxiety. Then there is the ever-present problem of the cost of living, which, in recent years, has steadily increased. It needs little argument to prove that the more children the lower is likely to be the standard of living with regard to a given income. It is, indeed, a point of no little significance that the decrease of the birth-rate has proceeded in inverse proportion to the increased cost of living. So far as the output of children is concerned, it is hardly surprising that a kindly, prudent woman should hesitate in bringing children into the world when she is unprovided with the means necessary to place them in a favourable environment as regards food, clothing, housing, education, and other conditions necessary to the uprearing of strong and capable citizens. Here, again, economic considerations play an indispensable part in the determination of conduct. The problem is no new one. Some years ago it was discussed at length in the columns of the Medical Press and Circular, both editorially and in the shape of formal articles by well-known medical men. There is much more to be said upon a subject which so closely affects all classes of society, individually and collectively. For some time past it has engaged the attention of the National Council for the Protection of Public Morals, a body which has many prominent clergymen, doctors, economists, and other distinguished workers amongst its members. Under its auspices a commission has been formed to inquire into the social, economic and racial significance of the falling birth-rate, and to suggest remedies. At a recent meeting held at the London Mansion House, presided over by the Lord Mayor, the matter was brought forward. Among those on the Commission were Dr. T. H. C. Stevenson, the Superintendent of Statistics for the Registrar-General, and Dr. A. Newsholme, Chief Medical Officer of the Local Government Board, with Bishop Boyd Carpenter as President. These names will command respect, and it is to be hoped that their deliberations will be fruitful of good results. The strong ecclesiastical element present in the parent Council reminds one of the change that has recently been evident more or less amongst the churchmen of all beliefs, namely, that it is their duty to succour the spiritual needs of mankind by seeking to advance their material welfare. One of the clerical members remarked that the Commission was not formed to discuss vague moral problems, a sentiment that chimes well with the breezy hopefulness of the Bishop of Birmingham, who thought there were signs that we might be in the dawn of the best age the world has ever seen. If the Commission labour in this spirit they are likely to add to our scientific knowledge of an intricate social problem of overwhelming importance.

THE LABOUR DISPUTE IN DUBLIN.

The labour dispute in Dublin presents features of more interest to students of public health and of social conditions than most industrial struggles, which in themselves are of more importance to the community. In the first place, the class of workers concerned is peculiar. The skilled tradesmen are not affected, except in so far as all industry is hampered by the results of the dispute. The fight is between the unskilled worker and the employer. Moreover, it is not only the unskilled worker in one class of work who is affected. The Transport and General Workers' Union embraces labourers of every class in the city and adjacent country—dock labourers, coal heavers, carters, tramway drivers and conductors, porters, factory hands, agricultural labourers, builders' labourers. As a consequence the employers affected are scattered widely through the community. Some are the biggest shipping firms, carriers, and builders, who employ hundreds or thousands of hands; others are small shop-owners, who perhaps only employ one or two delivery porters. It will be seen, therefore, that two facts stand out as of peculiar importance—that the dispute is unusually widespread and complicated, and that the workers primarily concerned are those whose normal condition is little above extreme poverty. It is not the function of a medical paper to examine the immediate causes which have led to the disastrous dispute, with its sympathetic lock-outs and sympathetic strikes. It is proper, however, to consider in how far the condition of the unskilled labourer in Dublin was such as to create the condition of temper which has rendered some such struggle as this all but inevitable. Mr. Larkin, the labour leader, has declared that it is his mission to preach a gospel of discontent. In Dublin he had no trouble to find material fitted for his purpose. There is no exaggeration in saying that the conditions of life of the Dublin working classes are a disgrace to civilisation. Readers of this paper must be aware that the death-rate in Dublin is the highest in Europe outside Russia. The mortality last year was 22 per 1,000 of the population—about 50 per cent. higher than that of London, Edinburgh, or Paris, and nearly twice that of Brussels, Copenhagen, or Stockholm. The infant mortality is similarly out of ratio to that of other civilised cities. The death-rate under one year of age in Dublin in 1912 was 140 per 1,000 births; in London it was 90; in 76 large provincial towns of England and Wales it was 104. As Sir Charles Cameron points out in his annual report on the health of the city, the mortality, both of children and adults, is specially high in the class described as "hawkers, porters, labourers, etc." They number roughly one-third of the population, and their death-rate last year was 30.6 per 1,000 of the population. Sir Charles assigns the great poverty of this class as the cause of the high death-rate, and there is no doubt that for the unskilled labourer wages are bad and employment uncertain. For these people life on economic conditions is almost impossible, and, even if they were well paid, decent housing cannot be obtained. Almost the only accommodation for the working classes is in tenement houses. These are not buildings erected specially as workmen's dwellings. They are, almost without exception, decayed private residences—some, it is true, large and spacious; others small and cramped. Whatever be their size, few of them have any indoor sanitary accommodation; one water-closet in the yard is used by anything up to fifty people. It is nearly always filthy. In 1912, to quote Sir Charles Cameron again, there were 21,113 one-room tenements occupied by one or more families. In 66 of these there were ten persons, or more, in each. In over 5,000 of them there were five or more in each. The filth and squalor of these houses cannot be described. Public attention has been forcibly directed to their condition by the sudden collapse of two houses a few weeks ago, resulting in the death of some seven persons. Up to the present, though praiseworthy endeavours have been made to provide dwellings for artisans, nothing has been done to meet the problem as far as labourers are concerned. Each slum clearance has increased the congestion all round. If the labour dispute has forced on the authorities the necessity of meeting this problem fairly, the strife and distress of the last two months will not have been wasted. Unfortunately, we cannot find as yet any serious disposition to deal with the matter. A request was made for a Vice-Regal Commission and the Chief Secretary has promised a committee of the Local Government Board *to sit in private.* It is not by this means that the deep-seated discontent of the Dublin workman is to be blotted out, and a plague-spot cleared from our country.

CURRENT TOPICS.

The Cultural Study of Spirochætes.

The demonstration given last week by Dr. Noguchi, of the Rockefeller Institute, New York, before the Royal Society of Medicine, records a further advance in the study of infectious diseases by the application of cultural methods of investigation. Three groups of spirochætes have now been cultivated by Dr. Noguchi, which may be termed tissue, blood, and saprophytic spirochætes. As a rule, ascitic fluid solidified with agar was employed as a culture-medium, and some twelve species of spirochætes have now been cultivated. Certain species need absolute anaerobiosis, while others require a small amount of oxygen to be supplied. In the domain of neuro-syphilology proof has now been given of the presence of the *Treponema pallidum* in the brain in cases of general paralysis. No less than 130 cases have been examined by a modification of Levaditi's method, and the organism was found in 36. Another recent triumph is the demonstration of the spirochæte in the spinal cord in cases of locomotor ataxy, thus removing any possible doubt as to the ætiology of tabes. The same cultural methods have been applied to the study of the virus of rabies, and also of that of poliomyelitis, for even an invisible virus can be grown under favourable conditions. It is a little early to estimate the practical bearing of these new discoveries upon therapeutics, but it is not unreasonable to suppose that a serum or a vaccine for the various forms of syphilis might even take the place of salvarsan or mercury.

London Fogs.

With the falling leaves of autumn come the unwelcome meteorological phenomena which all Londoners know so well. There is something tangible in a real London fog. It envelops, blinds, threatens and mystifies. Only the genuine pea-soup variety is the delight of the country cousin who is "dying to know what a London fog looks like"—and feels like, too—for where is the conjunctiva that can withstand the impact of countless myriad particles of solid carbon and sulphur and yet preserve, unblinking, a stony glare? Citizens of London do not mind fogs; they are used to them. In fact, they would miss them if they never came to remind mankind of approaching Christmas and a big laundry bill. Fogs cannot be called cheap luxuries—rather the reverse, for it has been estimated that a day of darkness in London costs about £5,000 for gas, as well as a large sum for electric light. The depressing effect upon the animal spirits more than counteracts the pleasureable sense of excitement experienced in endeavouring to avoid collisions with persons and inanimate objects. According to observations made by the Coal Smoke Abatement Society, it is estimated that no less than 61,000 tons of solid matter are deposited annually from the atmosphere in the City of London, and a very large proportion of this is waste carbonaceous matter which has its origin mainly in the domestic coal fire and kitchen grate. The gradual replacement of coal as fuel by gas is, to some extent, purifying the atmosphere, but much more yet remains to be done to minimise the inconveniences and dangers of fog. Meanwhile the average Londoner takes his fog, like his bath, as a matter of course.

The Psychology of the Sexes.

The fundamental difference between the mentality of the two sexes is by no means an unimportant factor in education. The quick, intuitive instinct of the female is soon apparent even at school, while the more stolid processes of reasoning which are supposed to be more characteristic of the male type of brain are equally in evidence. It appears that, as far as actual psychological differences between the sexes are concerned, these are less than might be imagined. Such, at any rate, is the opinion of Mr. Cyril Burt, Psychologist to the London County Council, who delivered an interesting lecture the other day on the subject before the Child Study Society of London. He said that until recently psychology had been engrossed in the study of the mental processes as a whole, and had neglected the individual mind. General psychology may have done much for education, but it is possible that individual psychology will do more. As a result of a number of experiments made to obtain data as to the mentality of school children, it has been found that girls and women are more acute in discriminating colours than boys and men. In fact, colour-blindness is extremely rare among females. Again, girls are said to be better visualisers than boys. On the other hand, there is a large number of faculties in which the male sex is superior. As for the innate reasoning powers of boys and girls, these also are as nearly as possible equal. It has further been shown that men are more emotional than women, and, as a matter of fact, very few women have earned distinction as writers of lyrical poetry. Women's emotions may be likened to the ripples on the surface of the water, while men's are deeper, like the ground swell. The experiments referred to, however, have been made only on a small scale, and it is possible that further research may upset the conclusions based on them.

Food in Newspapers.

The reprehensible practice of wrapping up eatables in newspapers is carried on to an extent little dreamt of, perhaps, by those who wonder what becomes of their morning and evening papers when read. These journals accumulate to such a degree that the perplexed housewife is only too glad to get rid of the surplus by selling them in bulk for a few coppers to the "old clothes man," who, in his turn, finds a ready market for them among the proprietors of fried fish shops and small stores. Those papers that are obviously soiled will, no doubt, find their way to the pulp manufacturer's to be "worked up" into various useful articles. The cleaner ones are greedily bought up by the small shopkeepers referred to, who use them for wrapping up all sorts of food, from sweetmeats to fried fish. It is no uncommon thing for a reversed image of the printed matter or actual paper particles themselves to be deeply ingrained upon the food. The matter was brought up the other day at a meeting of the Finsbury Borough Council, when it was pointed out that newspapers were often let to accumulate in dirty rooms, sometimes for years, before they were sold for this purpose. It would be interesting to know the result of a bacteriological examination of old papers. Most probably it would come as a "shocker" to a sensation-loving public, who might be deterred thereby from purchasing food wrapped in any other paper than clean white sheets, such as are used for dispensing purposes. It is useless to insist upon the cleanliness of food if it be served out to the public in filthy coverings.

The X-ray Diagnosis of Kidney Conditions.

The rapid development of X-ray diagnosis is well illustrated in the case of the kidney. A few years ago it was only now and then that a radiographic record could be secured of a renal calculus, not to mention the soft tissues of the organ concerned. Nowadays it is possible to secure an accurate record of the shape of the renal pelvis and of the ureters. In a recent paper on "Pyeloradiography," read before the Royal Society of Medicine, Mr. Frank Kidd discussed the latest phases of this important surgical advance. By injecting the ureters with a 5 per cent. solution of collargol in thin patients, and 7 per cent. in those that were fat, it was possible to obtain an accurate record with a short exposure of fifteen seconds. No anæsthetic is needed for the purpose, but certain precautions had to be observed. The quantity injected was from 4 to 10 cubic centimetres at a pressure not exceeding 30 mm. of mercury. Renal colic has been recorded in cases where too strong a solution of collargol was used, or where pressure or retention had been continued for too long a time. By this method deformities of the pelvis could be readily demonstrated, and it is clear that the surgeon may in future rid himself of the fear of operating upon a single kidney. Amongst other advantages claimed for pyeloradiography are the detection of early dilatation of the kidney pelvis, the differentiation of renal from other tumours, the exact position of a stone, the pre-operative condition of the organ, and the differential diagnosis of pyelitis, pyonephrosis and perinephritic abscess. The advances registered in Mr. Kidd's important paper contribute a fresh chapter to renal surgery, and place in the hands of the surgeon fresh means of accurate diagnosis and of correspondingly accurate operative procedure.

The Calendar of the Royal College of Surgeons of England.

Among the various works of reference that are usually to be found upon the medical practitioner's desk the roll of graduates of the university or the list of members of the corporation from which he obtained his qualification will figure conspicuously. The only drawback to these excellent publications is that they so soon become out of date. A new edition of the Calendar of the Royal College of Surgeons of England has just been issued by the Council. The list of Fellows now contains 1,589 names, while that of Members numbers 17,126. The number of diplomas issued shows a collective increase of 25 over that of the previous year, and includes 375 Members, 66 Fellows, 124 Licentiates in dental surgery, 41 diplomates in public health, and four diplomates in tropical medicine. With regard to the title of the latter diploma it has been decided to add a reference to the subject of hygiene, and the short title of "D.T.M.Eng." has been altered to "D.T.M. and H.Eng." Alterations in the regulations for the award of the Sir Gilbert Blane medals have also been made, and it is now provided "that one medal be awarded annually to the medical officer who obtains the highest aggregate marks at the examination for promotion to the rank of staff surgeon, now held twice a year in connection with the courses at the medical school of the Royal Naval College, Greenwich, the award to be subject to the approval of the Presidents of the Colleges of Physicians and Surgeons respectively and the Director-General of the Medical Department of the Navy." Previously two medals were conferred once in every two years on two medical officers of the Navy "who in the time required shall have delivered to the proper office journals evincing the most distinguished proofs of skill, diligence, humanity, and learning in the exercise of their professional duties." During the past collegiate year 39 Fellows and 250 Members have died.

Salol in Dentifrices.

The occurrence of an eczematous dermatitis around the mouth consequent upon the use of certain dentifrices, particularly those containing salol, is well known to dermatologists. It is sometimes exceeding difficult to trace the exact source of such an eruption until the tooth-powder or paste in use by the patient has been analysed. Then, again, there is the question of idiosyncrasy, for not every person who uses a salol-containing dentifrice will contract a skin disease therefrom. Our contemporary, the *British and Colonial Druggist*, in referring to the matter, mentions a case in which extensive eczema and "granulation of the neighbouring tissues" occurred after the use of a preparation of this kind, and states that neither phenol nor salicylic acid, the decomposition products of salol, are "likely to produce eczema." If an irritative dermatitis, indistinguishable clinically from ordinary eczema, be known to occur after the application in sensitive subjects of, say, dilute carbolic acid, to the epidermis, there is no reason why such an eruption should not follow upon the lips if a watery solution of salol be allowed to play upon them. Whether the exciting agent be due to an impurity, as has been suggested, or to the salol itself is not definitely known, but at any rate it is wiser not to recommend the use of dentifrices which contain salol or allied substances to patients with sensitive skins, even though the quantity present be apparently insignificant.

PERSONAL.

Dr. Charles E. Fitzgerald has been elected President of the Royal College of Physicians of Ireland.

Dr. Tom Stansfield, M.B., B.S.Lond., has been appointed Assistant School Medical Officer to the Somerset Education Committee.

Sir William Turner, K.C.B., Principal of Edinburgh University, opened last week the new anatomy rooms for women in Surgeons' Hall Edinburgh.

Col. T. D. Collis Barry, I.M.S., has been appointed Physician in charge of the X-ray Department of the *Dreadnought* (Seamen's Hospital Society).

Mr. William Paynter Noall, M.S.Lond., F.R.C.S.Eng., has been appointed Surgeon with charge of Out-patients to the York County Hospital.

Dr. A. K. Chalmers, Medical Officer of Health of Glasgow, has been elected President of the Society of Medical Officers of Health for the ensuing year.

Professor Sir Thomas R. Frazer, M.D., F.R.C.P. Edin., has been appointed Chairman of the recently constituted Clinical Medical Board by the Edinburgh University Court.

Dr. D. A. Reid, late Medical Officer of Health of Tenby, was presented the other day with an illuminated address and a cheque in recognition of his valuable services to the town.

Mr. Balfour S. Nicholson, M.B., M.C.Glas., D.P.H., Assistant Medical Officer of Health and Assistant School Medical Officer for Fife and Kinross, has been appointed Assistant Tuberculosis Officer and Assistant Medical Officer of Health for the same counties.

The Council of the Royal Institute of Public Health announce that they have accepted the offer made to them by Professor William R. Smith, M.D., to present annually a gold medal of the value of £20, "for conspicuous services rendered to the cause of preventive medicine within the British Empire." It is proposed that the first award shall be made in 1914.

Dr. William Russell has been appointed to the Moncrieff-Arnott Chair of Medicine in Edinburgh. Dr. Russell is Senior Physician to the Edinburgh Royal Infirmary, and Dean of the School of Medicine for Women, in which he has taken a deep interest. His career has been a distinguished one, commencing with the gaining of the gold medal for his thesis for the M.D. degree in 1884, followed by the Cullen Prize in 1893, and he has always associated himself in all movements for the general welfare of the profession.

AN ADDRESS

ON

THE VISCERAL COMPLICATIONS MET WITH IN HYSTERECTOMY FOR FIBROIDS AND THE BEST METHODS OF DEALING WITH THEM. (a)

By SIR JOHN BLAND-SUTTON, F.R.C.S.Eng.,

Surgeon to the Middlesex Hospital.

Twenty years ago abdominal hysterectomy for fibroids was performed by clumsy methods and attended by a high mortality. In the Middlesex Hospital, during 1892, the uterus was removed on account of fibroids three times; two of the patients died as a result of the operation, but in 1912 there were 71 abdominal hysterectomies for fibroids in the same hospital, and all the women recovered. A marvellous improvement in twenty years. To-day, hysterectomy for fibroids is a common operation with a mortality varying from 1 to 5 per cent. in the hospitals of London, general and special. I have chosen 1892 for comparison with 1912 because it is the year in which Baer, of Philadelphia, introduced the method now known as subtotal hysterectomy and inaugurated a new era in the surgery of the uterus. A *technique* of the operation varies very little with different surgeons, and I believe that the small mortality attending this operation can be further reduced. During the last 10 years discussion has mainly centred around the subtotal and the total operation. I do not propose to discuss *technique*, but I believe some valuable information can be obtained by a consideration of the visceral complications associated with fibroids. So many of these tumours have been removed that there are many surgeons who can count their hysterectomies in hundreds, and I believe that some useful facts can be collected if they would be willing to relate their experience in regard to the effects of fibroids on the circulatory system, the thyroid gland, the renal organs, and especially in relation to diabetes. These are conditions on the borderland of medicine and surgery. It will also be interesting to learn how surgeons deal with certain visceral lesions which occasionally complicate fibroids such as cancer of the colon, injury of the ureters, gallstones, and cancer of the breast.

Cardiac Lesions.

Fibroids are often present in women suffering from chronic cardiac disease, and it has been maintained by several writers that uterine fibroids cause degenerative change in the muscular tissue of the heart. It is true that many patients with fibroids have valvular lesions, a consequence of rheumatic fever, and, in many women who have been reduced to a condition of profound anæmia by a sub-mucous fibroid, the heart yields a loud murmur on auscultation. I have had careful observations made on the cardiac condition of women with fibroids, and there is nothing which can be described as peculiar to the influence of these tumours. It has been my practice for many years in selecting house surgeons to choose officers who have filled a resident appointment under a physician of repute. All patients with fibroids, before being set down for operation, are the subjects of a careful medical examination. On a dozen occasions I have removed the uterus containing large fibroids although the heart has furnished murmurs, clearly due to valvular lesions, when an examination by a competent physician has shown that compensation has been satisfactory and that an operation would not be attended with unusual risks. Indeed, in some instances the removal of a uterus, big with fibroids, from a patient with valvular disease will relieve an embarrassed heart. For example: A stout woman, æt. 50, with a large ovarian cyst and a fibroid the size of a football, suffered from dyspnœa due to a dilated heart and myocarditis. The anæsthetist would not risk a general anæsthetic, but we felt that if the tumour could be removed great relief would follow. The tumours were removed under an intra-dural injection of novocain. Convalescence was rapid, the cardiac symptoms disappeared, and the patient soon became robust and has since led an active and useful life.

The heart is a very adaptable organ and it is comprehensible, when we consider the size and vascularity of some fibroids, that the extra amount of work thrown upon it would lead to its enlargement. I believe that some cases of sudden death which occur within a few days of hysterectomy for fibroids happen in women the subjects of chronic, but unrecognised, disease of the heart. Some of these deaths are attributed to pulmonary embolism, but no death should be so assigned unless there has been a *post-mortem* examination and the embolus found. On this occasion I do not propose to discuss fatal post-operative pulmonary embolism, except to remind surgeons that recorded statistics indicate its occurrence in 1 per cent. of women who submit to abdominal hysterectomy for fibroids. I have recently published evidence which indicates in no uncertain way that it is often due to the exuberant use of buried sutures for closing the incision in the abdominal wall.

The Thyroid Gland.

From time immemorial it has been known that some mysterious relationship exists between the thyroid gland and the genital organs. No explanation has been found. The brilliant suggestion of Gaskell (in his fascinating account of "The Origin of Vertebrates") that the mammalian thyroid is the representative of the uterine glands of a palæostracan ancestor (of which the scorpion is a type) stimulates but fails to satisfy. To-day the matter is further complicated by the discovery of a relationship between the hypophysis and the genital glands on evidence at which even the most practical surgeon cannot scoff. On three occasions I have removed a uterus containing fibroids from women æt. 30, 33 and 35, who at the time of the operation possessed goitres. I have been surprised on seeing the patients six months after the hysterectomy to notice marked diminution in the size of the goitrous thyroids. In 1908, a spinster, æt. 44, suffered from menorrhagia due to multiple fibroids, but she had exophthalmic goitre and the thyroid was enlarged. It occurred to me that as the removal of the uterus for fibroids causes a goitre to shrink, such a sequel might be expected if hysterectomy was performed on this patient. After careful consideration I removed the uterus with the ovaries and tubes by the subtotal method. The operation was performed at the Middlesex Hospital and lasted twelve minutes. Chloroform was used for the anæsthesia. Before operation the patient's temperature was 99° Fahr. and the pulse rate 130. Twenty hours after the operation her temperature was 102° Fahr. and the pulse rate 140 per minute; but the thyroid gland had markedly decreased in size, and the eyeballs were less prominent. Forty-eight hours after the operation she was in a desperate condition. The temperature was 104° Fahr., pulse rate 180 per minute, and the thyroid gland had further diminished in size. The patient died fifty-six hours after the operation. A *post-mortem* examination was not permitted. This experience confirms the opinion that women with well-marked exophthalmic goitre are bad subjects for any operation.

(a) An address delivered at the opening of a discussion at the Medical Society of London, on Monday last, October 27th.

Diabetes.

The presence of sugar in the urine is, as a rule, a contra-indication to hysterectomy for fibroids. All patients requiring hysterectomy who come under my care have their urine carefully examined for sugar. It is a serious responsibility to operate on a patient whose urine contains sugar, but the risk must be faced in exceptional cases.

A widow, æt. 43, passed sugar in the urine to the extent of 5 grains per ounce. She suffered from menorrhagia, her menstrual periods lasting on an average ten days, the excessive bleeding depending on a large submucous fibroid. The patient wished to re-marry and was deterred from doing so, not by the glycosuria, but the menorrhagia. She wished to have the tumour removed and was willing to face the risks. I performed a subtotal hysterectomy. The operation was followed by a quick and uneventful convalescence; the patient married again and was in good health three years after the operation.

The following case is more instructive: A married woman, æt. 69, had a large uterine fibroid. There was free bleeding from the vagina at frequent but irregular intervals, which led me to suspect that cancer existed in the body of the uterus as well as a fibroid. The patient was diabetic, the urine contained 10 grains of sugar per ounce. I performed subtotal hysterectomy in 1904. The uterus contained a large submucous fibroid and a cancerous mass the size of a tennis ball. The patient recovered; she was alive and well in 1912—eight years after the operation.

I am sure, as a rule, it is a wise thing to abstain from performing hysterectomy on diabetics, especially young women. I have gathered from facts related to me by surgeons that such operations are attended with a high mortality. In some cases hysterectomy has been performed without the surgeon suspecting diabetes until the diuresis and the odour of the patient's breath, or the supervention of coma, led to an examination of the urine. Before leaving the subject of diabetes in relation to hysterectomy there is one aspect of it which is worth consideration. A large amount of evidence has been accumulated which tends to show that there is some interaction between the hypophysis and the genital glands. In acromegalic women menstruation is suppressed and, in some of them, the urine contains sugar. Experimental evidence has also been adduced which is supposed to prove that the hypophysis enlarges temporarily during pregnancy. Marek reported the following observation: A woman, æt. 26, was in the eighth month of pregnancy when she noticed that her gloves and boots became too tight. Her fingers thickened and the rings on them had to be removed with a file. She became sleepy and thirsty; sugar appeared in the urine. Gradually she assumed the coarse skin, thick lips and projection of the lower jaw characteristic of acromegaly. The child survived its birth, and in a few months the signs of acromegaly in the mother disappeared.

A large submucous fibroid produces similar changes in the uterus to those set up by the growth of a fœtus. Glycosuria occurs with sufficient frequency, as a complication of normal pregnancy and of fibroids, to make it conceivable that the uterine changes incidental to the growth of the fibroid may influence the hypophysis and thus be indirectly responsible for the glycosuria. Some years ago it was the fashion to tell a woman who wished to have her uterus removed for fibroids, that after the operation the skin thickens and she would grow fat and coarse. Experience teaches that the reverse is true. Women with large submucous fibroids are more or less in a condition resembling chronic pregnancy. Such patients sometimes become gross and fat and acquire a thick skin like acromegalics, but after a successful hysterectomy these unpleasant conditions disappear as in Marek's patient. We know nothing of the condition of the hypophysis in patients who have had the uterus removed for large fibroids. I hope pathologists who have an opportunity of inquiring into this matter will help us.

The Renal Function.

The close relationship of the uterus, bladder and vesical segments of the ureters leads to many complications when the uterus is occupied by fibroids and the changes which follow in the bladder, ureters and kidneys, if the tumour is of such a size and shape as to cause retention of urine, are well known. The urine of patients with a large cervical fibroid, or a fibroid of the body of the uterus impacted in the pelvis, often contains slight traces of albumen. This is not a contra-indication to operation, and the albumen quickly disappears after the tumour has been removed. Some years ago systematic examinations were made of urine drawn from patients under my care within the first thirty-six hours after pelvic operations, such as ovariotomy and hysterectomy, and it was found in nearly every case to contain the colon bacillus. I am unable to offer any explanation of its presence. This is worth mention; obstetric physicians are unable to make anything better than a guess as to the mode by which the urinary system is invaded by the colon bacillus in that troublesome condition known as pyelonephritis of pregnancy. Chronic urinary troubles of septic origin do occur in association with uterine fibroids, but I have never seen anything comparable to the acute suffering which is sometimes seen in pregnant women when the colon bacillus invades the kidneys and ureters. One of the most serious accidents that happens in the course of hysterectomy is an injury to both ureters. This is serious enough when the accident is detected in the course of the operation, but it is more unfortunate if it remain undetected until the nurse draws attention to the emptiness of the patient's bladder. No reliable estimate of the frequency with which ureters are injured in the course of hysterectomy for fibroids is forthcoming. British surgical literature contains few references, but it is only necessary to turn over the pages of the *Zentralblatt für Gynækologie* to be satisfied that they are often cut. At the present time, when a ureter is injured in the performance of abdominal hysterectomy, the surgeon endeavours to anastomose the cut ends. Failing in this he implants the proximal end in the bladder wall. Urologists do not approve of this; they insist that when a ureter is engrafted into the bladder it becomes sclerosed by chronic ureteritis, which narrows and finally obliterates its lumen. This sclerotic obliteration does not happen in every case. Lockyer, in removing a fibroid which burrowed between the layers of the broad ligament, wounded the bladder and divided the right ureter. He repaired the hole in the bladder and removed the kidney. During the twenty-four hours following the operation the bladder remained empty. Lockyer re-opened the abdomen and found the left ureter cut. He engrafted its proximal end into the bladder through the wound which had been already sutured. Convalescence was retarded by a urinary fistula, but Lockyer's resourcefulness was rewarded, for the woman recovered and was in good health three years later.

Many years ago I was present at a hysterectomy when a gynæcologist cut three inches out of a ureter mistaking it for an adhesion. He tied the proximal end of the cut ureter with a silk thread. The patient, a middle-aged woman, recovered without an untoward sign and remained well. This led me to take a special interest in this method of dealing with a cut ureter. In 1909 I expressed the opinion that it is possible, and probable, that a ureter has been tied in the course of a hysterectomy and the patient has recovered without anyone having a suspicion that such an accident had happened.

Dr. J. D. Barney collected and classified the reports of sixty-two cases in which the ureter was injured. Of these, sixteen were bilateral and forty-six unilateral. The majority of the accidents occurred in the course of hysterectomy. He notes that sudden occlusion of the ureter by a ligature often produces no symptoms: sometimes it is followed by pain and tenderness in the kidney which subside spontaneously. In some instances the accident is followed by hydronephrosis, and he reiterates the opinion, which I have already expressed, that there is strong probability that a ureter is often unconsciously tied in the course of hysterectomy. If gynæcologists would tell us how they treat cut ureters this discussion would be justified, for, if it is only necessary to tie the proximal end of the cut ureter, the way out of an embarrassing accident would be greatly simplified.

FIBROIDS AND CANCER OF THE COLON.

Fortunately uterine fibroids rarely contract adhesions to the intestines unless the uterus and Fallopian tubes have been the seat of infection, gonorrhœal or puerperal. It is unusual for the surgeon to be hampered with bowel complications when he undertakes hysterectomy for fibroids, but he may have to deal with cancer of the sigmoid flexure of the colon, or the upper part of the rectum. It has happened to me on several occasions in the course of removing the uterus for fibroids to find cancer of the sigmoid flexure. After completing the hysterectomy I excised the cancer in the colon and joined the cut ends of the bowel by an end-to-end anastomosis. In a woman blanched from profuse and oft-repeated uterine bleeding, due to a cervical fibroid, I removed the uterus and its neck (total hysterectomy), and, in adjusting the intestines preliminary to closing the incision, detected a cancerous focus in the sigmoid flexure of the colon. The patient had sustained a serious operation, and in her weak condition I did not think it wise to excise the bowel. She made an excellent recovery, and was kept under observation. Two months later I excised the growth, and she recovered easily from the operation, and was alive and in good health two years later.

The growth of cancer in the colon is often slow and insidious, and there is a massive form of colic cancer which, during its symptomless stages, is indistinguishable, especially when the mass lies in contact with the uterus, from a subserous fibroid. The diagnostic signs are sometimes especially deceptive if there should at the same time be a few small hard fibroids in the uterus. Sometimes I have undertaken an abdominal operation hoping to find an impacted fibroid, but have found a hard cancerous growth in the sigmoid flexure impacted in the pelvis, and the operation has ended in colotomy. In happier cases I have started on the operation with strong suspicions that the patient had a malignant mass in the bowel, but found an impacted fibroid. It is a most evil combination when a fibroid of moderate size occupies the uterus and a massive cancer of the sigmoid flexure adheres to it. I am not alone in such experience; some of my gynæcological colleagues have occasionally stumbled on a cancerous pelvic colon in mistake for a fibroid, and have assigned the patients to their surgical associate for the operation of resection.

UTERINE FIBROIDS AND GALLSTONES.

Gallstones are common in women; so are fibroids, and it sometimes happens that women come under observation with the two conditions giving so much trouble that the surgeon is puzzled to know which should be dealt with first. On three occasions I have removed a calculous gall-bladder in the course of hysterectomy for fibroids. In each instance the uterus was so large as to require for its removal an incision reaching nearly to the ensiform cartilage. In these circumstances the removal of the gall-bladder was a simple operation. In one instance the inflamed gall-bladder adhered to a large subserous fibroid. In two other instances of this combination I removed the gall-bladder six months after the hysterectomy. The only definite rule which I think can be laid down in the matter is this: If a woman deeply jaundiced in consequence of a stone impacted in the common duct also suffers from a uterine fibroid, which so troubles her as to make it desirable to remove the uterus, I should prefer to remove the stone from the common duct first, because it is well known that cholæmia predisposes to hæmorrhage. Hysterectomy in a woman with persistent jaundice is an operation which would place her life in the gravest peril from post-operative bleeding.

The pelvic complications of uterine fibroids, such as ovarian cysts, pregnancy, pyosalpinx, inflamed appendix, and the like, are so common and so well understood that they have no place in this discussion. We are anxious to obtain the experience of those who perform hysterectomy for fibroids, especially in relation to such complicating conditions as heart disease, goitre, diabetes, renal disease, and cancer of the intestine. Fatal accidents in *technique* (such as hæmorrhage and shock) occur occasionally like railway collisions and deaths from lightning, but post-operative deaths from heart disease, pulmonary embolism and injuries to the ureters will be fewer if we profit by the experience of those who have faced these difficulties. In this way the risks of hysterectomy for fibroids, though small, will be reduced, and, small as they are, I am sure we have not reached the irreducible minimum.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Dr. Froelich, Professor Agrege in the Faculty of Medicine, Nancy. Subject: "Is it Necessary to Operate in Spina Bifida?*

ORIGINAL PAPERS.

THE INTESTINE AS A PATHWAY OF INFECTION TO THE TUBERCLE BACILLUS, WITH SPECIAL REFERENCE TO THE PART PLAYED BY ENTERITIS. (*a*)

By LEONARD FINDLAY, D.Sc., M.D.

Assistant Professor to the Practice of Medicine, University of Glasgow.

In view of the great divergence of opinion regarding the question as to whether the healthy intestinal mucosa is pervious to the tubercle bacillus, and because it is one of great practical importance, the author carried out a series of experiments with improved *technique*. The *causa morbi*, in the form of culture of the bacilli, was suspended in oil and placed in a gelatine capsule which was slipped just within the nozzle of a stomach tube and ejected by forcing a stream ot water through it after its passage into the stomach. It had been previously found that the introduction of an emulsion of the bacilli per the stomach-tube almost invariably gave rise to insufflation tuberculosis, and any abdominal operation for its introduction direct into the stomach or intestine allowed infection of the peritoneum.

In consequence of the frequency with which catarrhal conditions of the intestine are present in childhood, the period of life in which the tubercle bacillus is believed to enter most frequently by the intestine, the question was studied in normal rabbits and in rabbits which had recently suffered from intestinal catarrh. This was induced by means of an infusion of senna and gamboge. Both the human and bovine types of the tubercle bacillus were experimented with. In a series of 12 healthy animals, fed as above described with bovine tubercle bacilli, and killed at periods varying from four to ten days later, living tubercle bacilli were demonstrated by animal experiment in the mesenteric glands from two of the cases. In another series of five rabbits which had previously suffered from diarrhœa and were killed six to eight days after the ingestion of the organisms, living bacilli were demonstrated in the mesenteric glands in one case. In neither series were living bacilli found in the lungs.

In healthy rabbits fed on living tubercle bacilli and allowed to live for prolonged periods tubercular lesions were discovered in all those that survived at least 50 days. The appendix and adenoid patch at the ileo-cæcal valve were invariably the seat of nodules, the mesenteric glands less frequently, and the lungs only when the experiments were at least of 70 days' duration. In a similar series of long period experiments in which the rabbits had previously suffered from enteritis, induced by gamboge and senna, tubercular lesions developed as early as 19 days, and were present in all that survived at least 30 days. The lesions were similarly distributed, but were much more extensive and more frequently generalised. A diarrhœal animal presented lesions at 20 days as extensive as those found in a healthy animal after a duration of 60 days.

The great majority of healthy rabbits fed on tubercular sputum and on emulsions of human tubercle bacilli and allowed to live for long periods afterwards did not develop tuberculosis. In 16 animals so treated tubercle bacilli were detected on one occasion in films of the mesenteric glands. In two healthy rabbits, to which 20 mgrs. of a young culture of the human type of tubercle bacillus were administered by gelatine capsule, and which were allowed to live for periods of 96 and 117 days, tubercular lesions were detected. In the 96-day experiment very slight but definite lesions were present at the ileo-cæcal valve, and in the 117-day experiment a suspicious-looking nodule about the size of a pinpoint was present also at the ileo-cæcal valve; but microscopic examination revealed the presence of tubercle bacilli only in the first case. In both, however, very definite tubercular foci were situated in the lungs. Of five rabbits which had previously suffered from diarrhœa, four, killed at periods varying from 37 to 63 days after the ingestion, presented tubercular lesions. The animal which remained free from tuberculosis had recovered about eight days from the symptoms of enteritis, whereas in the other animals the inoculation took place only two days after the cessation of the diarrhœa. The lesions when present were situated in the appendix and adenoid patch at the ileo-cæcal valve, and in the mesenteric glands. As one could understand, the lesions with the human type of the bacillus were much less extensive, and, in marked contrast to the experiments with the bovine type of organism (where the intestinal mischief was invariably the most extensive), the lungs in the healthy rabbits and the mesenteric glands in the diarrhœal animals were more severely affected than the bowel. Indeed, in one of the non-diarrhœal animals, the lungs alone were definitely diseased and it would thus seem possible for the primary intestinal lesion to heal and an apparently primary glandular or pulmonary tuberculosis to result.

The conclusions drawn from the experiments were :—1. Healthy rabbits can be infected by the ingestion of large amounts of bovine tubercle bacilli. 2. The bacilli can pass through the apparently intact intestinal mucous membrane and reach the mesenteric glands within a period of six days; this, however, does not frequently occur. 3. When infection occurs, the intestine is invariably the seat of lesions, and thus tuberculosis of any organ, other than the intestine, is always a secondary infection when the bacilli have entered by the intestinal route. 4. Catarrh of the intestine does not favour the passage of the tubercle bacillus through the wall, but allows of a more constant and also of an earlier and more widespread infection of the bowel, and in this way facilitates dissemination. 5. Healthy rabbits can be infected by the ingestion of large amounts of the human tubercle bacillus. 6. Rabbits just recovered from intestinal catarrh develop tuberculosis more easily and much sooner after the ingestion of human tubercle bacilli. 7. With the human type of organism, a local lesion, though always present, may be slight in comparison with the deceased foci in the mesenteric glands and lungs. 8. In digestion experiments with the human type of the bacillus, it would seem possible for the local lesion to heal and all trace of the portal ot entry to be lost. 9. It would seem that the best means of combating the spread of bovine infection in childhood, so long as the removal of

(*a*) Abstract of Paper read before the Glasgow Medico-Chirurgical Society, October 17th, 1913. (See page 480.)

the source is not tackled, is the avoidance of everything likely to cause intestinal catarrh, and the use of sterilised milk.

PLEUROGENIC REFLEXES IN THE LIMBS.

By Dr. HANS FINSTERER,
Privat Dozent in Surgery, and Assistant, Universitats Klinik, Vienna.

[Specially Reported for this Journal.]

In the Congress of Surgery held last year, von Saar read a communication (*Archiv fur Klinische Chirurgie*, xcix., 243) in which he discussed the occurrence and significance of sensory and motor derangements of the extremities, supervening upon lesions of the pleura in cases in which the original injury did not in any way involve the affected limbs. His attention had been directed to this rare clinical phenomenon, by meeting with a case in which reflex paresis of the left upper extremity developed after a penetrating wound of the left pleural cavity. This led him to examine the literature of the subject, and the comparison of the data of eight cases which had been previously reported; also to further research on the subject by a series of experiments on animals with the object of being able to throw some light on the clinical and pathological significance of the phenomenon. Regarding the relative infrequency of this clinical accident, on the one hand, and the importance of its recognition for diagnosis and indication of appropriate treatment—medicinal and mechanical—on the other, I may be allowed to place before the reader a brief account of a case which recently appeared in Professor Hochenegg's Klinik, and was carefully observed by me.

An official, æt. 53, was brought into the accident department of the Hochenegg Klinik, on the evening of June 22nd, 1912. A short time previously he had attempted suicide by shooting himself in the left mammary region. On being questioned in detail, the patient stated that he had felt sharp neuralgic pains in both lower extremities immediately after the attempted suicidal wound; also, that cramp-like spasmodic contractions and twitchings appeared at intervals, and lasted for about thirty seconds; soon after the lapse of which the legs could be moved voluntarily again without any pain or apparent deficiency of normal power.

On admission the patient displayed the Stokes syndrome; startling pallor of features; pulse 118. The breathing was very frequent. In the seventh intercostal space, a finger's breadth outside the mammillary line, was to be seen the opening left by the shot-wound; its margins were blackened by the powder. On the left side of the thorax there was abnormal dulness over a hand's-breadth area; no blood-stained expectoration. The abdominal walls did not present any abnormal tension; there was no abnormal area of dulness discoverable; the neighbourhood of the first and second lumbar vertebræ was markedly sensitive to pressure. During the process of percussion of the thorax, the patient complained of acute pains in both the lower extremities; especially in the thighs, and on the left side more than on the right. Also, it was noticed that on taking a deep inspiration, the more acute pains located in the thighs travelled down into the legs; and, on this account, the patient carefully avoided taking a deep inspiration.

On examination with the Röntgen rays, the projectile was located close to the first lumbar vertebra; on the left side of the latter, and on a plane somewhat posterior to the body—which had not been injured by the missile.

The treatment at first consisted of absolute rest in bed, with administration of morphine. There was no substantial improvement of the hæmothorax. The pains in the legs gradually subsided, but could still be vividly elicited after the lapse of a week by vigorous percussion of the thorax, or by deep inspiratory movements. There was no apparent defect of motor power or motion, either active or passive. With regard to the psychic condition of the patient, which had been markedly querulous, there seemed to be no traces of any erratic disposition observable at the close of an interval of ten days. At the time of discharge, the paræsthesia had almost completelydisappeared. And on inquiry into the subsequent history of the patient, it was ascertained that no permanent sequelæ of the original injury had remained.

The principal feature of importance associated with a knowledge of pleurogenic reflexes of the extremities is that of their diagnostic significance. The patient whose case is described above had been sent on to us by the Rescue Society, with the apparently correct diagnosis: "Gunshot wound of the spinal cord." At first sight this diagnosis seemed to be borne out very closely by the facts of the existence of pains in both lower extremities, and the periodic recurrence of muscular cramps. By the interesting communication of von Saar my attention was, for the first time, directed to the rare clinical phenomenon of pleurogenic reflexes of the extremities; and, in the case of which I have just detailed the symptoms, the recollection suggested special enlightenment regarding the significance of the complication—on account of the decided absence of pronounced motor lesions, and, even more especially, by the fact that the pains in the limbs were always elicited and emphasised by percussion and by deep inspiration; which, having regard to the nature and history of the original injury (a shot fired with the right hand into the left side of the thorax) would have, at first sight, appeared very unlikely to find a satisfactory explanation in associated cause and effect. Then the Rontgen-ray investigation of the position of the projectile which distinctly located it on the left side of the first lumbar vertebra, with which it was not in immediate contact, revealed a condition which absolutely excluded any attempt at explanation by mechanical injury of the spinal cord.

The question how the appearance and development of these reflexes can be accounted for can hardly be said to be satisfactorily answerable at the present time; inasmuch as we still possess but a very limited number of recorded clinical observations, and a few reports of experimental researches. We have but some apparently plausible grounds for the belief that the medium of conduction in those very rare reflexes is furnished in some cases by branches of the vagus (Cordier), and in others by twigs of the intercostals which lie beneath the parietal pleura. That anæmia of the spinal cord, produced by reflex contraction of the spinal vessels resulting from peripheral stimulation (Brown-Sequard), can hardly be taken as an intelligible cause of the cramps and pains in our cases, is fairly deducible from the fact that they may be made to appear so promptly by percussion of the thorax.

Had the pains developed, in our own case, in the left lower extremity exclusively, the position of the projectile, near the left side of the first lumbar vertebra, would have at once suggested a direct nerve lesion as the probable cause. But such could not be suggested by the symptoms actually observed, for the bilateral development of which concussion of the lumbar section of the spinal cord with consecutive capillary hæmorrhages would be requisite, according to this view—which was most unlikely, from the limited degree of traumatic injury. Thus there remains, in way of explanation of the origin of the symptoms in our case, only the view that it was the result of reflex stimulation, commencing in the pleura and possibly, as might be concluded from Cordier's experimental researches on animals, switched therefrom to the nearest conducting branches of the vagus.

Quite recently (*Deutsche Zeitschrift fur Chirurgie*, cxix., 1912) Zesas has given an exhaustive and lucid account, based on his own observation and the critical analysis of 53 cases collected from all the sources of the literature of the subject, of the various reported accidents associated with operative lesions of the pleura (as in tapping for empyema, etc.), which in rare instances have been followed by development of reflex spasms in various parts of the body—leading in special circumstances to a dangerous series of sequelæ, and even to a fatal issue. Those cases present a very considerable degree of similarity to the rare examples of reflex phenomena which appear after gun-shot injury of the pleura.

It should be borne in mind that a knowledge of the occasional occurrence of such pleurogenic reflexes is of great importance from the therapeutic view-point. This fact is forcibly illustrated by the history of our own case, in which adoption of the view that the symptoms which developed were due to organic lesion of the spinal cord would necessarily have led to very active therapeutic procedure; while, with the accurate knowledge of the facts which we were able to obtain, a purely symptomatic treatment, in which the administration of morphine was one of the principal factors, proved sufficient to lead to a successful issue. Zesas also ascribes a great degree of curative efficacy to the employment of this therapeutic agent in the class of cases of which he has so carefully collated the literature; indeed, he not only attributes to it the power to allay the pains and spasms which have already developed, but also relies upon it for prevention of such accidents occurring after puncture of the pleura, when judiciously administered in time as a prophylactic.

THE VARYING DEGREES IN THE MALIGNANCY OF EPITHELIOMA.

By F. T. PAUL, D.Sc., Ch.M., F.R.C.S.

The earliest histological research into the mysteries of cancer was a primitive form of cytology. It was useless to clinicians. We learnt nothing of practical value from it. Of late years improved *technique* and more perfect instruments have enabled capable researchers in this branch of study to give us much information of great scientific interest and value regarding the nature and character of cancer cells; but up to the present all the knowledge derived from histological research which has been of real practical use has come from the study of the time-honoured section. Cytology is an adjunct to minute anatomy. It does not supersede it, for there are just as many varieties of cancer cell as there are of tissue cell.

Spindle-celled tumours, innocent and malignant.

Modern methods give us clearer and more definite pictures of the minute anatomy of tumours, and with increasing experience we interpret them better, and so obtain more guidance for prognosis and treatment.

Between tumours which are innocent and those which are intensely malignant there are many intervening stages ; but we cannot give a definite name to each grade because the path of evolution follows a different line in the different types of tissue. Thus, in the fibrous connective-tissue tumours there are, between fibroma and soft spindle-celled sarcoma, growths of every degree between innocence and malignancy. Many of these are classed under the name of sarcoma, and as some are very malignant, whilst others are hardly so at all, more definite classification is needed to avoid confusion. Experience has taught us that if the nuclei are large, irregular in size, and show marked mitotic changes, and the cell wall is not defined, the growth is very malignant, involving a wide removal and a bad prognosis. If the nuclei are more regular and elongated, and the cell wall clearly defined—like, for example, the spindle cells in a myeloid epulis—the case is more hopeful. If the cell wall is continued into fibrillar branches the tumour is on the border line of innocence. If the nuclei are linear and the cells have completely fibrillated, the tumour is perfectly innocent. (Figs. 1 to 4.)

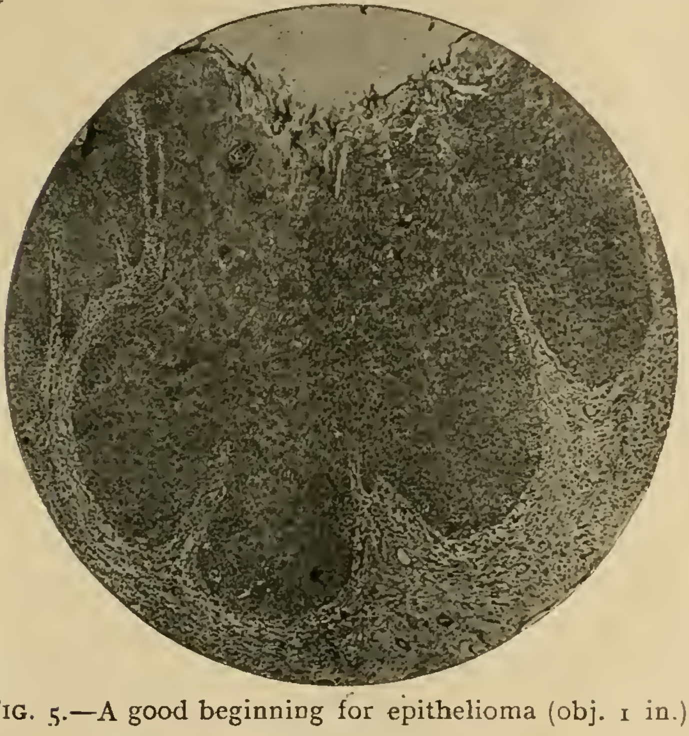

FIG. 5.—A good beginning for epithelioma (obj. 1 in.).

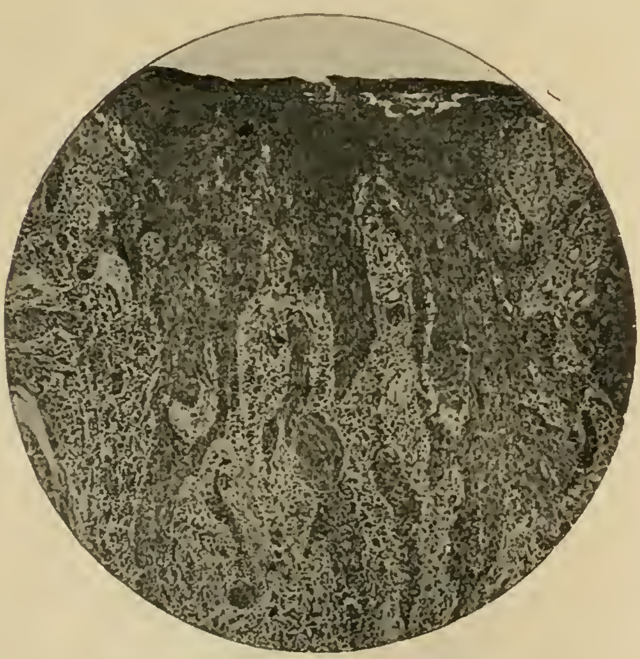

FIG. 6.—A bad beginning for epithelioma (obj. 1 in.).

Squamous epithelial tumours are subject to somewhat similar variations. These are not as clearly marked as in the case of spindle-celled connective-tissue growths, but one is able to point to many features which are sufficiently constant to prove helpful.

Apart from the histological appearances, which will be dealt with presently, there are certain preliminary points which should always be taken into consideration. The first is, *to get the case early*. This eclipses every other detail, for I find that of late years the patients operated on at an early stage have almost invariably been cured, even although the patient may have been young and the growth of malignant type. The second is, that *warty growths are better than ulcerating growths*. The more malignant a growth is the sooner it breaks down and ulcerates. A cauliflower type of epithelioma may attain considerable dimensions and still be completely cured by a clean removal. I have had many examples in proof of this on the body as well as in the mouth and larynx. The third is, that *epithelioma originating in scars, embryonic rests, and sebaceous cysts is usually under the average in malignancy*. Such growths are often chronic in type and remain localised for a long

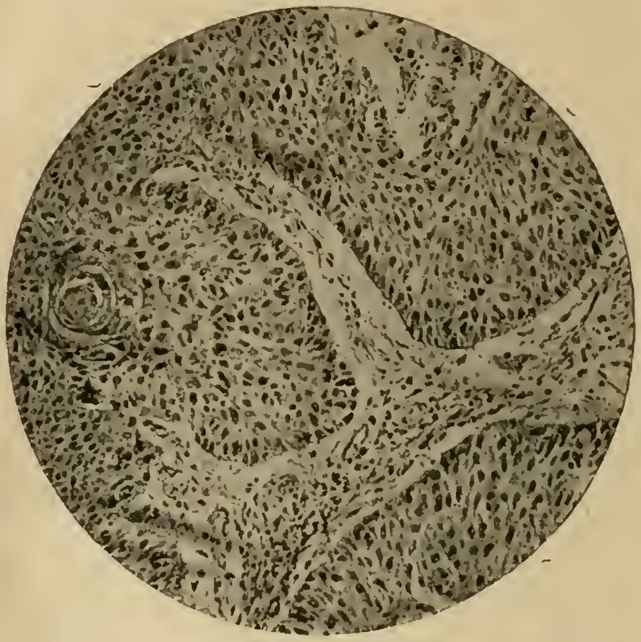

FIG. 7.—A mildly malignant epithelioma of the papillomatous type (obj. $\frac{1}{4}$ in.).

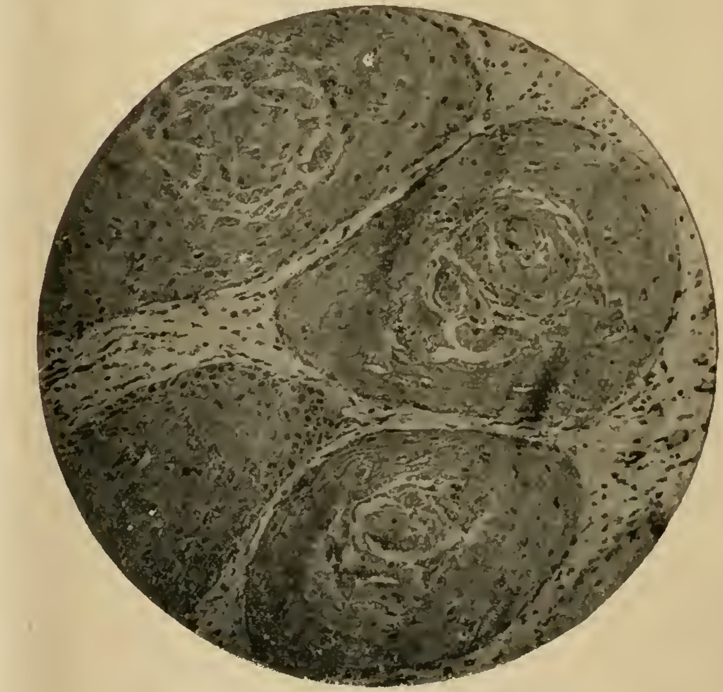

FIG. 8.—A chronic epithelioma (obj. $\frac{1}{4}$ in.).

time, though ultimately a change for the worse may be relied upon. The fourth is, that *epithelioma commencing in a source of chronic irritation is usually very malignant*—such irritation as a dental ulcer, or especially a superficial syphilitic glossitis. The more marked the irritation, the more rapidly will the tumour grow, and the more infiltrating will its nature be.

Regarding the histological appearances, the following are the points to be noted :—

(1) *The commencement.*—When the case is seen on at an early stage, good and bad starts may be observed. The best is a localised chronic warty tumour of the type shown in Fig. 5. The downgrowths should consist of good broad cylinders of epithelium, and the basal irritation should be clearly defined, not spreading far into the underlying tissues. The worst is a widespread downgrowth of fine trabeculæ of epithelium over an ill-defined area of chronically irritated tissue as in Fig. 6. The former never infects the glands in this early stage, and complete local removal is permanent cure. The latter is the type met with in the syphilitic tongue, and secondary distribution may take place at any time.

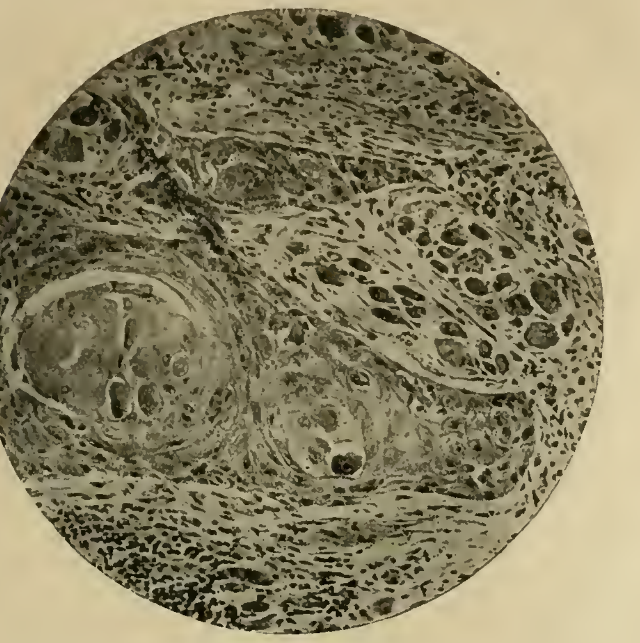

Fig. 9.—A very malignant epithelioma of the ulcerating and infiltrating type (obj. $\frac{1}{4}$ in.).

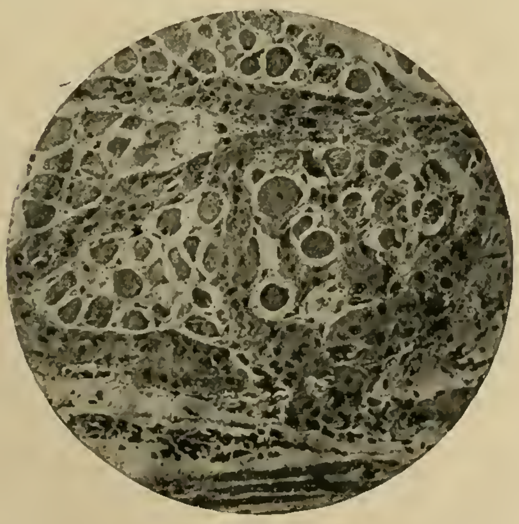

Fig. 10.—A bad lymphatic infection amongst the muscle fibres of the tongue (obj. $\frac{1}{4}$ in.).

(2) *The cell-type.*—One of the best is that there should be large trabeculæ of small cells of uniform type, and with only a slight tendency to the formation of "nest-cells" (Fig. 7). This variety of growth is usually met with in the warty kind of epithelioma, which, though infiltrating, is definitely localised. Such growths have afforded very good operation cures in mouth, tongue, and larynx cases. Another good cell-type is when the epithelium trabeculæ consist of clear-looking, equal-sized cells with smallish nuclei, and the intervening connective tissue is small in amount, fibrous in character, and shows little or no leucocytosis (Fig. 8). This is the appearance met with in chronic forms of epithelioma, like those which may attain a large size in old burn scars without secondary infection. A further favourable type, though not so favourable as the foregoing, is one in which there are large horny nest-cells surrounded by a narrow layer of growing epithelium. The more this character predominates throughout an ordinary epitheliomatous tumour, the more likely it is to be fairly localised, and the better is the patient's prospect after a thorough operation.

The bad cell-types show irregular groups of cells, many of which are small. The individual cells and their nuclei vary much in size, some usually being strikingly large. Nest-cells are always in evidence. The intervening connective tissue is swollen and shows marked leucocytosis. The growth is ill defined, remnants of the normal muscle or other tissue being visible amongst the groups of cancer cells (Fig. 9).

(3) *Definite limitation at the base of the growth.*—This is most important. A bad type, so long as it is definitely limited gives the surgeon a chance of complete local removal, though he may fail subsequently owing to a too wide infection of the lymphatic glands.

(4) *Lymphatic infection.*—The worst feature is to find tumour cells in the lymphatic vessels and spaces outside the area occupied by the growth (Fig. 10). Such cases as these recur locally as well as in the neighbouring lymph glands, and rarely offer any chance for a permanent cure. Early fixation and marked pain and tenderness are usually features of this type of infection.

Every surgeon of experience has witnessed brilliant cures following operations of a limited nature ; and also rapid recurrence and death in other cases, though every resource of modern surgery has been most thoroughly and conscientiously utilised. A consideration of the foregoing details helps to explain such apparent anomalies. If the information is sometimes only available when it is too late to influence the treatment, it is still valuable for forecasting the future, and in time one learns to anticipate the microscope, so that one feels almost sure by the history, appearance, mobility, tenderness, etc., of the growth what type it will prove to be, and how one should plan the attack to be made upon it.

THE SUPERVISION OF THE HEALTH OF CHILDREN BETWEEN INFANCY AND SCHOOL AGE. (*a*)

Report by W. W. JAMES, F.R.C.S., L.D.S.,
London.

The importance attached to the condition of the oral cavity in its relationship to the general health is associated with a notable development of medicine in recent years, namely, the recognition of regions in the body from which secondary infective processes or toxæmias may arise. A most valuable comparison can be made between these regions, and important

---

(*a*) Paper read before the Section of Stomatology, International Congress of Medicine, August, 1913.

as many are, the mouth is probably of chief significance.

The importance of the state of the oral cavity has long been known; for generations the doctor has looked at the tongue, but he should have looked further and examined the teeth. The diminished glandular activity of fever is well observed in the mouth, and in part, perhaps, accounts for the examination of the tongue; but the condition of the mouth is chiefly dependent upon the state of the teeth.

That pathological changes are more frequent in the mouth than in any other part of the body will hardly be denied, and that these changes are chiefly dependent upon the teeth and the tissues supporting them must be allowed, as the lesions otherwise occurring in the oral cavity do not differ markedly from those of other parts.

It is a fact of some significance that the Stomatological Section has been chosen to take part in a discussion upon the supervision of the health of children at this International Congress.

The influence of the mouth upon the general health is dependent upon two main factors, the efficiency of the teeth for mastication and their freedom from pathological lesions; the latter being of far greater importance than the former, although it is true one is dependent upon the other. Ill effects which result from an unclean mouth are due in part to its position at the portal of the alimentary tract, the food swallowed besides not being masticated is contaminated by micro-organisms or their toxic products, and also to direct infection of remote parts through the blood or lymph vascular system, either by micro-organisms themselves or by their toxic products, which have been produced in the tissues supporting the teeth.

The great difficulty of establishing the relationship of a lesion in a remote part with the mouth condition is such that at present our knowledge is based almost entirely upon clinical experience. The condition which has come to be known as " an unclean mouth " or " oral sepsis " is dependent either upon one or both of the two chief pathological lesions of the dental tissues, dental caries and pyorrhœa alveolaris. The supervision of health, therefore, regarded from the point of view of the stomatologist, must comprise the prevention of conditions favourable to these dental lesions or if established their treatment in order that they may not become extensive or dangerous to the patient.

During the period under discussion, between infancy and school age, most important changes are taking place in the mouth and neighbouring parts. Our considerations must comprise certain points in the normal development of the parts; and the deviations and pathological changes which have been established during infancy, which may arise during this period and which may be prevented in the future. It is most necessary also to consider the means which can be adopted to maintain the mouth in a healthy state both by the patient and the dental surgeon.

The normal development of the teeth and jaws is so closely related to the neighbouring parts that for a complete study it would be necessary to describe the progressive changes which occur in the bones of the face. For our present purpose it is sufficient to consider certain points in normal development which may undergo deviation and produce conditions favourable to the more serious pathological dental lesions.

At the time of completion of the temporary dentition the teeth should be evenly arranged in well-developed arches, their crowns should be free of the gingival tissues with the root implanted in marked alveolar processes. The occlusion of the teeth resembles that of the permanent series, except that the posterior surfaces of the second temporary molars of the maxillæ and of the mandible are almost in the same plane, the maxillary tooth being only very slightly posterior to that of the mandible.

The temporo-mandibular joint is most imperfect when compared with the adult joint, the surface for the reception of the condyle being almost flat. The state of this joint is most significant, for its development would seem to depend upon the future relationship of the maxillary and mandibular teeth. An anatomical consideration of the movements which occur in the temporo-mandibular joint should really include the articulation of the teeth surfaces of the opposing jaws, for the movements of the joint are dependent, in many positions, upon the articulation of the teeth.

The relationship between the development of the nasal cavities and the jaws and dental arches is of the utmost importance, on account of the great frequency with which maldevelopment of the one is associated with maldevelopment of the other. The deviation in the development of the jaws, from clinical experience, would appear to be secondary to the state of the nasal cavity; but some observers hold the converse is true, that the mouth condition is primarily at fault. Our present knowledge of the primary causes is so limited that we can speak from little more than clinical experience.

The succession of changes in the process of development of the jaws during the period under discussion comprises growths of the bones and eruption of the permanent teeth with loss of those of the temporary series.

The development of the bones is such that the additional space required for the permanent teeth is supplied, growth takes place in several directions, but the exact changes are not definitely known. It seems possible that the presence of the teeth may have a special influence; interstitial growth has been assumed to take place in the mandible, although it is most difficult to conceive.

Prior to and during the period of eruption of the permanent teeth the development of the jaws can be observed. The dental arches increase in size, the incisor teeth of the temporary dentition become spaced; the jaws in the region of the temporary molars are wider, as has been shown by measurement in a few cases; and the jaws show an increase in length in the antero-posterior direction in order to allow the first permanent molar to come into position. A change which, in the opinion of the writer, is of great importance, consists of an alteration in the relationship of the mandible to the maxillæ. Previous to the eruption of the first permanent molars the mandible appears to develop in such a manner that the incisors no longer occlude posteriorly to those of the maxillæ, but assume a more or less edge-to-edge occlusion. The marked attrition of the temporary incisors is explained by this change, and is an indication whether it is occurring or not. The normal occlusion of the first permanent molars is permitted by this change; but if it does not take place the mandibular teeth will probably assume a post-normal relationship, as the second temporary molars will still have their posterior surfaces in almost the same vertical plane. The establishment of this view is difficult, as the movements of the mandible are so free in a child, a very wide range being possible. Models show the edge-to-edge occlusion is probable, but also that other positions are possible. It is sufficient to examine the mouths of children to be sure that this edge-to-edge occlusion occurs. It is my opinion that a case calls for careful consideration if the attrition marks on the temporary incisors are not definitely seen at the age of five and a half years.

Normally the teeth should stand upon well-formed alveolar processes; too little attention has been directed to imperfect development in a vertical direction, probably because the treatment of the condition appears almost hopeless. This condition is only too common, and is associated with recognised imperfections in the development of the jaws.

Some of the causes of imperfect development of the dental arches are known, but our present knowledge cannot be regarded as other than vague. That nasal obstruction is a most potent factor is certain; that loss of temporary teeth at an early age is a cause of much importance has long been recognised, although in some cases ill effects do not result; of the deformities caused in infancy, those produced by habits constitute a larger group than has been thought; the general development of the child may be impaired by ill-health, by insufficient or poor food which may have a local effect as in the case of rickets. Local affections also may exercise a marked influence.

The interest which is now being taken in the deviations from normal development of the temporary dentition should be productive of a far greater knowledge than we now possess of the normal changes in the jaws. Until quite recently dental surgeons did not attach much importance to the stages prior to the eruption of the permanent teeth.

With regard to the eruption of the permanent teeth it is impossible to enter into a discussion of the various views held. The changes are of the greatest importance, and need be referred to only so far as they influence the prevention of dental lesions. Most observers will allow that the temporary teeth are lost by a process of absorption, and that the tissues supporting these teeth are, for the most part, also removed. If a tooth be examined prior to the date of eruption, by cutting sections, the crown is found to be merely covered by the overlying tissues, but the root from the neck downwards is very differently related, the tissues being closely attached. It is difficult to conceive "eruption" of the tooth without a corresponding change in these attached tissues.

The views of the writer, that eruption is brought about by the growth of the tooth and its supporting tissues, which causes advancement, and by denudation of the crown, at first by the opening out of the overlying tissues along the remains of the tooth band, and later by the actual removal of these tissues, may not be generally accepted, but that the final process is one of absorption will hardly be doubted.

The final stage in which the loose tissue about the crown of the tooth is removed, leaving the gum closely attached to the neck and protected by the projecting enamel, is so important that it cannot be passed over, for in those cases in which it is incomplete a predisposition to pathological changes of the utmost importance has been established.

The completion of eruption appears to be brought about by the removal of the soft tissues as the result of stimulation by friction when food is eaten, and the advantage of a type of food which is capable of doing this is obvious.

The effect of pituitary and thyroid secretions upon the growth of the jaws and the eruption of the teeth are insufficiently known to be of clinical value, but it may be mentioned that benefit is said to have followed the use of thyroid extract in cases of nasal obstruction.

Much stress has been laid from time to time upon inherited characteristics; how far these play a part in producing conditions favourable to dental lesions is uncertain. That the face of the offspring often so closely resembles that of the parent should be sufficient to prove that their jaws are similar; but that the same dental pathological lesions will occur does not follow. Future investigations from this aspect will certainly be of interest, and may prove to be of great value.

Normal development should result in the arrangement of the teeth in perfect arches with correct occlusion, and probably no one will disagree that when this occurs dental lesions are less likely to supervene. The dental surgeon should endeavour, therefore, to achieve this end, whilst normal function by the patient should be encouraged for the same purpose.

The commonest deviations from normal development, where the cause can be recognised as having occurred during infancy, are due to:

Mechanical Distortion.
Caries of the Teeth and their Loss.
Nasal Obstruction.
Constitutional Disturbances.

Mechanical Distortions primarily affect the anterior part of the jaws and are the result of constant and repeated pressure upon a firm substance placed between the teeth. The object is usually described as being sucked, and the deformities resulting are spoken of as due to "sucking a teat," "thumb-sucking," "finger-sucking," "tongue-sucking," and although sucking may be the reason of their introduction into the mouth, it is really the pressure of closing the jaws which causes the deformity.

Teats, whether upon bottles or as dummies, may be used without ill effects; but the deformities at times are considerable and of sufficient frequency to condemn their use, apart from their dirty condition, which is so usual. In cases of deformity from this cause the child has been allowed to sleep with the teat in the mouth. If a child be watched in which deformity has occurred, it will be seen at intervals to vigorously and rapidly close its jaws upon the teat, and when the mouth is examined a displacement of the tissues is seen which accurately fit against the teat when placed in position. The deformity involves the maxillæ more than the mandible; the maxillary central, and occasionally the lateral incisors, are displaced forwards and upwards, but what is more important is the similar displacement of the alveolar process carrying the teeth. The mandibular teeth may show little displacement; they may be slightly depressed, tipped inwards, but rarely outwards.

In nearly all these cases distortion of the alveolus is present, and the position of the permanent teeth will almost certainly be affected.

The method of prevention in these cases is obvious, although at times very difficult to carry out. If the cause be removed the lips will normally exercise sufficient force to correct the deformity, but it may be necessary to introduce an appliance such as is described later for the prevention of mouth-breathing. In the case of tongue-sucking a vulcanite palate plate with a flange projecting downwards behind the front teeth and worn at night will usually be effective.

The deformities, although variable, are generally characteristic of the different factors which cause them. The teat deformity is seen at the earliest age; it occurs in the middle line, involves the incisors, the central maxillary incisors chiefly; the teeth are often carious, and extensively so in those children for whom the teat has had honey or sugar put upon it, as is frequently done.

The deformity due to thumb sucking is usually more marked on one side of the arch than the other, and involves more teeth than in the case of the teat. Tongue-sucking may be seen occasionally in the molar region as well as anteriorly; the deformity often affects the canines as well as the incisors; when the teeth are occluded, a space forming a narrow slit is seen between the maxillary and mandibular teeth; the cause may be difficult to establish if the tongue is sucked only at night.

Dental Carries in the temporary dentition is so common that it is more usual to find it present in one or more teeth than a complete absence of it.

The fact of chief importance is that caries most frequently commences in the fissures of the molars. It is also commonly found in the incisors; a dirty teat is the cause in many cases, whilst in others mouth-breathing may be present. Maldevelopment of the teeth, in children with a history of constitutional disturbance such as rickets, is a common cause, and often the predisposing factor in those cases where all the teeth in the mouth are affected. It has been thought that hypoplasia of the temporary teeth is rare; but those who have examined the mouths of a great number of children will have recognised imperfections in development of the teeth which are only too common.

The secondary affections associated with caries in the temporary teeth are of such importance to the subject under discussion that they cannot be passed over.

The first ill-effect occurs when the function is impaired, the teeth are painful, and in consequence cease to be used; particles of food remain upon the teeth and caries commences in others besides those which are already affected.

Normal development is interfered with not only by the infection of the tissues, but by the loss of the temporary teeth. Where the crown of a tooth has been lost as a complete tooth has been removed the neighbouring teeth are forced together by the tension of the lips and cheeks, flattening of the arch results, leading to a diminution in size, which may have a marked effect upon the future position of the permanent teeth.

The presence of a root which is infected prevents normal absorption of the temporary tooth from taking place. This is probably due to the toxic products acting upon the tissues which should bring about the absorption. The presence of the septic root may cause marked deviation of rotation of the permanent successor.

Dental caries also leads to impaired mastication, which diminishes the stimulus to development of the jaws and permanent teeth.

The effect is very important upon the whole alimentary tract, for food is not masticated and is contaminated with micro-organisms and their products.

Local inflammatory conditions of the mucous membranes of the mouth are present and sometimes severe; cases of necrosis of the bone may result, and not infrequently necrosis of permanent teeth occurs, usually of the premolars. It is quite common to find hypoplasia of a permanent tooth due to the inflammation associated with a temporary tooth.

The uncleanliness of the mouth which results from dental caries leads to infection of other parts. In my own experience several cases of chronic otitis media have been arrested completely by rendering the mouth clean; the nasal obstruction had been treated, but the chronic suppuration in the ear continued, in spite of local treatment, until the mouth was rendered clean. The operation in cases of adenoids should not be undertaken, with our present knowledge, until after the mouth has been treated.

The association of infection of the mouth with enlargement of the lymphatic glands in the neck is well known. The experience in my cases may be of interest, as careful records were kept over a long period and a very large number of children examined.

The lymphatic glands particularly associated with mouth lesions are the upper cervical glands beneath the upper part of the sternomastoid, the glands and nodules closely connected with the connective tissue of the parotid and submaxillary salivary glands, and the submental glands.

The cervical glands are best examined by standing behind the patient, whose head is bent forwards and towards the side being examined. The other glands are best felt by a finger being introduced into the mouth to depress the floor, whilst the fingers of the other hand are used beneath the mandible externally.

In all children the glands are palpable, but when healthy can only just be felt, and are freely movable. When irritated, probably by toxic products rather than directly infected, they are felt to be enlarged, soft, and only slightly tender if at all, and usually movable. If definitely infected they will be tender, more or less fixed, and perhaps softening at one point. After removal of the teeth and cleansing of the mouth the glands can still be felt, but they have contracted and are felt as small, firm nodules.

The possibility of glands irritated in this manner being infected by the tubercle bacillus is of much importance.

Prevention of dental caries will be dealt with later in my paper.

The treatment of caries in the temporary teeth consists of filling cavities and the extraction of teeth in which the pulp is involved. Some modification is perhaps necessary to both of these statements, but taken as general principles they are, in the opinion of the writer, quite sound.

If the child is difficult to manage and many teeth are carious, extraction is indicated. The second temporary molars should be saved, if possible—the loss of these teeth has more effect than any others upon the future development; they may be removed if the first permanent molars are in occlusion or when the caries involves that part of the tooth which is next to the permanent molar. The loss of the anterior teeth leads to diminution of the corresponding part of the arch of the permanent series, but the correction of this condition is usually easy when the occlusion of the first permanent molars is normal.

Under all circumstances the mouth must be rendered clean, and if removal of the temporary teeth be the only way to achieve this end they must go; correction of ill effects, if necessary, can be undertaken later.

Nasal Obstruction and Mouth-breathing are powerful factors in causing maldevelopment of the jaws. Different views are held as to whether the mouth-breathing or the nasal obstruction is the primary fault—the majority of observers incline to the latter. This subject is being discussed at one of the meetings of the Stomatological Section, but some reference to it here is necessary.

(*To be concluded.*)

OPERATING THEATRES.

BOLINGBROKE HOSPITAL.

A Case of Cut Throat.—Mr. Swainson operated on a case of cut throat. The history of the case was as follows:—The patient, a man, æt. 75, cut his throat with a razor. The wound extended from the left sterno-mastoid muscle to the right at the level of the upper edge of the thyroid cartilage of the larynx, and divided the thyro-hyoid muscles, cervical fascia, and anterior wall of the pharynx. The epiglottis was completely cut from its attachment to the thyroid cartilage, and the common carotid arteries were exposed but uncut. The patient had lost much blood. the case was temporarily treated in the out-patient department as follows:—The bleeding points were ligatured; a stitch was passed through the upper border of the larynx and of the skin of the neck to prevent the larynx from slipping down into the wound. The patient was then admitted to hospital and seen by Mr. Swainson, who performed the following operation:—A preliminary tracheotomy was first done, and a tracheotomy tube stitched into the opening. The original wound was next dealt with. It was first gently mopped out with some biniodide lotion, care being taken to avoid the larynx. The epiglottis was sutured with catgut to the thyroid cartilage, and the lateral walls of the pharynx were similarly sewn up. Silkworm-gut sutures were then passed through the skin, cervical fascia and the muscles, and the wound closed. Drainage tubes were inserted in each end of the wound, which was then cleansed with biniodide in spirit, 1-500, and dressed.

Mr. Swainson said that the first thing to deal with in cases of cut throat was hæmorrhage. There was also danger of asphyxia from blocking of the larynx. In this case it was found that the patient breathed better when the larynx was drawn up by seizing the thyroid cartilage in the middle line with a vulsellum and making traction in an upward direction. It was advisable, he thought, to sew up the wound in layers with catgut sutures so as to restore as far as possible the normal condition of the parts. As the wound was necessarily septic owing to its communication with the pharynx, it was also necessary to provide free drainage, as had been done in the present instance. When the larynx was freely opened, as in this case, it was advisable to perform tracheotomy. The after treatment would consist in keeping the parts absolutely at rest with constant supervision of the patient and very careful feeding. Unfortunately these patients frequently succumb to pneumonia, usually septic in origin. As sequelæ fistulæ sometimes formed, there was occasionally stenosis of the larynx and trachea and sometimes aphonia from injury to the recurrent laryngeal nerve.

On returning to the ward the patient was propped up in bed and continuous saline given per rectum. Shortly after his return to ward the metal tracheotomy tube slipped out of the trachea, and had to be replaced by a piece of rubber tubing about three inches in length and split at upper end in order to make two flaps, which were stitched to the skin at the sides of the tracheotomy wound. The cause of slipping out of the metal tube was the depth of the trachea at the tracheotomy wound from the skin surface; this permitted only the end of the metal tube to lodge in the trachea. No fluids or food were administered by the mouth, but a nutrient enema of

Glucose, oz. i.,
Egg albumin, oz. i.,
Brandy, oz. ½,
Saline, ad oz. vi.,

was given. The patient unfortunately succumbed to pneumonia on the following day.

General Septic Peritonitis Complicated by Pregnancy.—The same surgeon operated on a woman, æt. 35, who had been admitted with the following history:—The patient was 5½ months pregnant, and about 60 hours previous to admission had been suddenly seized with acute abdominal pain and vomiting. The vomiting was continuous, while the pain, which had first been felt in the right side, had later become general, with acute exacerbations resembling labour pains. On admission she had a temperature of 100.8°, the pulse being 120, and the respirations 32. The abdomen was distended, rigid and tender. The tongue was coated and dry. An enema resulted in a large constipated motion, with passage of much flatus, which to some extent relieved the distension of abdomen.

Mr. Swainson saw the patient one hour after admission, and decided upon immediate operation. Under anæsthetic of open ether, a preliminary vaginal examination revealed an os dilated to admit the tips of two fingers, and through which intact membranes and active fœtal movements could be felt. A median incision about 6 in. in length was made from just below the umbilicus to the symphysis. On opening the peritoneum free pus was met in the peritoneal cavity, and a large gangrenous perforated appendix in the iliac fossa. The peritoneum was inflamed and coated with flaky lymph. The appendix was removed and the peritoneal cavity swabbed out and then flushed with saline. Two large drainage tubes were inserted into both sides of the pouch of Douglas, and the abdomen closed by through-and-through sutures of thick Pagenstecker thread.

Mr. Swainson remarked that the patient was clearly suffering from peritonitis as shown by the rigid, tender and distended abdomen. The temperature of 101° also pointed to this, and the pulse was 120 and the breathing was thoracic. There had been a history of sudden pain in the iliac fossa, which rather suggested the onset of appendicitis, and the patient was also pregnant. As the cause of the peritonitis was uncertain, it was decided to open the abdomen in the middle line. A free opening in this situation gives the most ready access to all parts of the abdomen, and is afterwards most easily and quickly sewn up by through-and-through sutures. Speed is most important in these cases; if possible the operation should not take more than half an hour. It is advisable to mop up the pus with large dry swabs and rolls of gauze. If there is a great deal of general extravasation flushing with saline solution is useful. If possible, the cause of the inflammation—in this case gangrenous appendix—should be removed if it can be done speedily. Free drainage must then be provided by means of rubber tubes and sometimes gauze, and then the patient should be quickly returned to bed and placed in the so-called Fowler position, with the head and shoulders raised, and saline infusion per rectum should be given continuously. By this means toxines are diluted and got rid of. Later on a solution of glucose per rectum would help to nourish the patient, whose normal alimentary functions were in abeyance.

The patient was put back to bed with the head and trunk raised, and continuous rectal saline commenced. Six hours after operation the patient aborted. The fœtus, which was delivered from a breech presentation, breathed for an hour. After the abortion the patient was given pituitary extract, 1 c.c., intramuscularly, and continuous rectal saline was recommenced. The saline was stopped at the end of 36 hours, by which time she had received four pints and a half.

The wound discharged copiously for ten days, and the thread sutures which closed the abdominal wound became infected. The stitches were painted with iodine and also fomented, and later a dressing of emulsion of iodoform and glycerine was applied. One pelvic drainage tube was removed on the third day after operation, and the other was replaced by plugging gauze on the tenth day. The through-and-through sutures were removed on the fourteenth day and a firm scar resulted. The wound was painted with tinc. iodine daily.

Three weeks after operation the patient's temperature and pulse were normal, and on the 32nd day she was allowed up on a couch. The temperature had never reached 102°.

TRANSACTIONS OF SOCIETIES.

HARVEIAN SOCIETY OF LONDON.

Clinical Meeting held at Paddington Green Children's Hospital on Thursday, October 16th, 1913.

Dr. Leonard Guthrie in the Chair.

CASES SHOWN.

The President showed several cases of congenital hereditary nystagmus and head rolling.

Dr. G. A. Sutherland, a case of cœliac disease in a child. A case of a child with auricular fibrillation of which some interesting heart tracings. Also a child three years after the removal of the left kidney for sarcoma by Mr. Burghard. For two years there was an apparent cure, now recurrence had taken place.

Mr. Gauntlett showed a case of ulnar paralysis following the separation of the lower epiphysis of the humerus. The nerve had been freed from the callus by which it was surrounded. A case of ischæmic paralysis after a fracture of the olecranon.

Dr. Hay, a case of bacilluria.

Dr. Haldin Davies, an extremely severe case of ichthyosis in a young man.

Mr. Leonard Ball showed a series of dental cases, ranging from six to ten years.

Mr. Duncan Fitzwilliams showed a case of which a lipoma had been removed from under the parietal pleura, also a fibrolipoma from under the deltoid; it had been attached to the capsule of the shoulder joint. Also a case of tumour in the upper part of the abdomen in a child, the nature of which was uncertain.

Dr. Perkins had arranged an exhibition of interesting microscopic and pathological specimens.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

Meeting held October 17th, 1913.

Dr. John M. Cowan, in giving a lantern demonstration on

AURICULAR FLUTTER,

reviewed briefly the literature on the subject. McWilliam, in 1887, showed that the application of an electrical stimulus to the auricle produced a premature systole starting at the point of stimulation. Faradisation of the auricles "sets the auricles into a rapid flutter, the rapidity of which largely depends upon the excitability of the auricle tissue and the strength of current employed. The movements are regular; they seem to consist of a series of contractions originating in the stimulated area, and thence spreading over the rest of the tissue. The movement does not show any sign of inco-ordination: it looks like a rapid series of contraction waves passing over the auricular walls," and thus differed from auricular fibrillation, in which the auricular contractions were inco-ordinate, much more frequent (500-600) and irregular. In 1905, Gibson and Ritchie reported, with polygraph tracings, a case of full heart block, in which, with auricular contractions numbering 246-300, the ventricular beats numbered 30 per minute; and in 1906 a similar case. Morrison, Hertz, and Goodhart also published similar tracings. In 1910 Jolly and Ritchie commenced investigations with the electrical polygraph, and, independently of others, isolated auricular fibrillation. They also examined the 1905 case of rapid auricular action and found that the auricular waves were regular, numbering about 300, and diphasic. They suggested that this might be the same as McWilliam's auricular flutter. Further observations by Ritchie, Lewis and others seemed to have established the identity of a new rhythm, and one that is not at all uncommon. Thirty cases have been published, and Dr. Cowan had found eight cases in his own collection with polygraph tracings, and many more in which its occurrence seemed probable. In illustration of the condition, a series of polygraph tracings was demonstrated.

Dr. Leonard Findlay read a paper, illustrated by lantern slides, on

THE INTESTINE AS A PATHWAY OF INFECTION TO THE TUBERCLE BACILLUS,

with special reference to the part played by enteritis, a full abstract of which will be found under the heading "Original Papers," page 471.

LIVERPOOL MEDICAL INSTITUTION.

The First Ordinary Meeting of the 75th Session was held on Thursday, October 16th, 1913.

The President, Mr. Robert Jones, in the Chair.

The President read an inaugural address on the views held by the late Mr. H. O. Thomas, more especially on

INTESTINAL OBSTRUCTION.

The works of the late Mr. Thomas, with the exception of his splints, were too little known, partly owing to his writings having been published privately. Mr. Thomas, writing in 1884, recognised the futility of the commonly advocated methods of treating intestinal obstruction—namely, by purgation, enemata and milk diet. He recognised that where a mechanical condition was the obstruction, no medical treatment could avail anything, but that in cases of functional obstruction it was possible by resting the bowel, by rendering the contents above the block fluid and non-irritating, and by relieving pain, to give a favourable termination to many cases. The treatment he advised was first to relieve pain by hypodermic injections of morphia, to allay thirst by the administration of water, and to withhold all food that would add to the contents of the intestine. Cases so treated might go on for from 40 to 50 days. Resolution occurred by the patient passing first flatus, perhaps some small scybala, then a large pultaceous motion followed by watery evacuations. Mr. Thomas was particularly anxious for his cases at this stage, enforcing complete rest and allowing food to be given only very gradually and of such a kind as to produce as little intestinal residue as possible. Mr. Jones alluded to the views of Ochsener, of Chicago, who had recommended lavage starvation, while he withheld cathartics.

Mr. Rushton Parker proposed a vote of thanks to the President, and was seconded by Mr. F. T. Paul.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Oct. 25th, 1913.

Treatment of Flatulence.

Flatulence, says Prof. Robin, is one of the most frequent symptoms of every form of dyspepsia, especially in that due to fermentation.

At the beginning of the process of digestion flatulence is purely gastric, later it becomes intestinal and manifests itself by quantities of wind and tympanites. It is characterised by frequent eructations and bubbling sounds synchronous with the respiration; the neighbouring organs are more or less compressed, provoking in many cases dyspnœa, oppression, palpitations and cardiac intermittence. When the gases cannot find a way of escape meteorism sets in, to the great danger of a weak heart.

Herschell believes that the cardiac compression may provoke sudden death, and those persons known to suffer from disease of the heart, who are found dead in bed in the morning, succumb during the night to syncope produced by flatulence.

Flatulence has a double origin : Gas developed during gastric fermentation; air swallowed with the food or otherwise (aerophagia).

The gases engendered by fermentation are but little abundant, but the presence in the stomach of air swallowed with the food increases the amount of gas developed during fermentation. These gases are composed of azote, oxygen, carbonic acid, but also hydrogen and, in certain cases, sulphuretted hydrogen. Contrary to what is observed in pure aerophagia, these gases are more or less odorous.

The treatment of flatulence due to gastric fermentation is that of fermentation. Small doses of fluoride of ammonium :—

Fluoride of ammonium 6 grs.
Water 10 ozs.

a tablespoonful in the middle of each repast (2).

In the case of lactic fermentation the double iodide of bismuth—erythrol—should be preferred,

Erythrol $\frac{1}{2}$ gr.
Prepared chalk 5 grs.

for one cachet; taken after meals.

The nature of the food ingested should receive attention; every article to be excluded that has tendency to ferment: pork, game, shell-fish, cheeses, grease, sauces, etc. It is also necessary to aid rapid evacuation of the stomach by giving bitters to stimulate the muscular coat of the organ—

Tincture of nux vomica 3 drs.
Hippo wine 1 dr.
Essence of aniseed 1 drop,

ten drops in a little water after meals.

Absorbents, and particularly poplar charcoal, are good adjuvants.

In the second variety of flatulence, that due to aerophagia, the ætiological characters are quite different. The digestive troubles are provoked, not by a dyspeptic condition complicated with gastric fermentations, but by the deglutition of quantities of air—enormous quantities in some cases. Fits of eructation appear at any moment; they are independent of the ingestion of food, come on spontaneously or under the slightest exciting cause, cease suddenly, are not painful. In most cases, aerophagia represents a simple neuropathic manifestation.

The treatment of this form is that of the cause—neuropathy. In slight cases, hydrotherapy, ether spray over the epigastrium, massage may be useful, but in aggravated cases these means are inadequate.

The patient should be instructed as to the nature of his affection, and advised to control the movements of deglutition. A good way of avoiding aerophagia outside of meals consists in keeping the mouth open as long as possible by means of a piece of cork or india-rubber placed between the teeth, thus involuntary deglutition is prevented.

Where the gas escapes with difficulty, tympanism and meteorism set in with all their complications. Here Seltzer water may be tried, ether may be given, while gentle massage is made over the epigastrium.

Salpingo-Ovaritis.

Salpingo-ovaritis is, needless to say, due to multiple causes: complications following confinement, spontaneous or provoked abortion, obstetrical or surgical operations, menstrual disorders, gonorrhœa, metritis, etc.

The impossibility of curing salpingo-ovaritis outside surgical interference was generally admitted; removal of the diseased appendages was the rule adopted by most medical men some years ago. However, a reaction has taken place in favour of preserving the organs to the patient when possible. As prophylactic treatment the chances of infection have been reduced to a minimum by the generalised use of antiseptics in confinements and all infections of the genital tract.

In presence of a case of acute or chronic salpingo-ovaritis, the medical attendant has in hand several active means which will frequently render operative measures unnecessary, if intelligently employed.

In acute cases: (*a*) Absolute rest in bed and in the horizonal position. (*b*) Warm applications over the abdomen, hot poultices moistened with

Belladonna oil, 3 oz.
Ext. of opium,
Ext. of belladonna, aa 1 dr.
Ext. of hyoscyamus,
Chloroform, 5 dr.

(*c*) Against fever, six or eight leeches loco dolenti and one of the following cachets—

Bichloride of quinine, 8 gr.
Powdered digitalis, 1 gr.

(*d*) Warm injections (113° F.) twice a day, with—

Boric acid, 2 teaspoonfuls.
Laudanum 50 drops.

For two quarts of water.

(*e*) Laxatives.

Chronic cases of salpingo-ovaritis are treated by warm rectal injections, plugs of cotton wool steeped in

Glycerine, 3 oz.
Tannin, 3 oz.

and applied to the cervix once or twice a day. Iodide of potassium is given internally—

Iodide of potassium, 1 dr.
Arseniate of soda, 1 gr.
Water, 10 oz.

Two tablespoonfuls a day after meals

The mineral water cure is frequently very efficient in removing exudations and adherences and relieving pain. Prof. Robin classes these waters according to their degree of activity—Biarritz, Salies de Béarn, Rheinfelden, Salins du Jura, Néris, Luxeuil, Plombieres.

GERMANY.

Berlin, Oct. 25th, 1913.

At the Aerztlicher Verein Stettin Hr. Kalb related a case of operation for obstinate constipation. He first pointed out the value of Roentgen illumination after giving bismuth by the mouth followed by injecting it into the bowel. The case (patient shown) was that of a man, æt. 34, who for years had suffered from the most obstinate constipation. The motions were passed at the most every three days, and that following the administration of very powerful purgatives, with enemata following. The illumination showed atony of the transverse colon, but more especially of the descending part. Laparotomy was performed with transverse section of the fasciæ after the method of Pfannenstiel. The atonic portions were excluded from the main intestinal tract by wide anastomoses between the commencing portion of the transverse colon and the sigmoid flexure. Recovery was uninterrupted. After the operation the bowels were opened twice daily without any medicines of any kind and without any change in the diet. X-ray examination after the operation showed that nearly all the contents of the bowels were passing through the short cut made by the operation.

Hr. Haeckel showed an infant for whom he had performed

Extirpation of a Suppurating Kidney.

The child, two months old, had had a panaritium, in connection with which necrosis of a phalanx had occurred. During the course of this suppuration had taken place in the left kidney, this had been incised Excessive discharge of pus took place from the opening and persisted for a long time. Two months later, when the infant was four months old, the incision was lengthened forwards—without the previous administration of an anæsthetic—in an oblique direction. Multiple abscesses were found in the fat around the kidney. The kidney was then after incision of the capsule shelled out and removed. In the upper surface was a large abscess which communicated with the outside, and which had been the cause of the other abscesses round the kidney. The wound was closed partly by suture and partly by tampons. The little thing stood the operation well, and now three months after it was quite well with the exception of a small secreting orifice. Staphylo and streptococci were found in the suppurating tissues, but no tubercle bacilli.

Hr. Freund, Jr., who had attended the child earlier, said the kidney process was a metastatic one, as was proved by the panaritium and the presence of staphylococci in the urine.

Hr. Kalb also related what he considered to be a

Unique Case of Peptic Ulcer of the Duodenum.

It was that of a infant only six weeks old who suffered from perforation of the bowel and purulent peritonitis. He was of opinion that the very early age of the patient rendered the case unique as far as regarded literature. Since the year 1904 there has been in existence in Berlin a society which has for its aim the watchful care of all cases of disease of the lungs, cancer and the victims of alcoholic excesses. The society sends visitors, nurses, or medical men who will undertake the duties to watch over and advise in these cases. In the case of drunkards, for instance, it is infinitely better for the patient that his steps should be watched over daily or even hourly if necessary, than that public-houses should be shut or even that publicans should be fined, however gratifying that may be. Interference with the sale of alcohol does not fall within the scope of the activities of the society. If a patient passes from one part of the city to another he is not lost sight of, but is simply passed on to an affiliated branch in that district. In the case of drunkards the patient's family is usually aroused to take an active interest in trying to save the patient against himself, and this has been followed by an encouraging amount of success. During the year 1912, 1,277 cases were taken in hand, in 646 of them the patient's family was roused to a sense of responsibility with prompt amelioration of the conditions. In 122 cases the drunkard was successfully kept within the bounds of sobriety and at work. No medicines are given, and there is no interference in the medicinal treatment of the cases.

At the Aerztlicher Verein Frankfort, Hr. Sasse reported two cases of

Total Extirpation of the Stomach.

The second case was one of special interest. It was that of a man, æt. 76, for whom a diagnosis of cancer of the stomach had been made. Partial resection was determined on. At the operation it was found that the carcinoma was very extensive and superficial, and that it was adherent to the adjoining parts. In order to mobilise and set free the stomach it was found necessary to remove a triangular piece from the mesocolon and also a portion of the pancreas. As the disease reached almost to the cardiac orifice of the stomach the operator determined on total extirpation. The stomach was therefore removed *in toto*, the duodenal opening closed and an upper loop of small intestine sewn into the œsophagus. The patient several weeks after the operation felt quite free from any intestinal troubles. (Skiagrams of the case were shown).

AUSTRIA.

Vienna, Oct. 25th. 1913.

The Use of Papaverin in the Differential Diagnosis of Stenosis and Spasm of the Pylorus.

Papaverin, which is an absolutely innoxious pharmacological and therapeutic agent, has been employed by Drs. Holzknecht and Sgalitzer, of Vienna, as an auxiliary to the Röntgen rays in the differential diagnosis of pyloro-spasmus and pyloro-stenosis. For this purpose it is administered by the mouth, in form of the hydrochlorate, in doses of 0.05 to 0.07 gramme. In case of a normally healthy stomach, it procrastinates the expulsion of the contents for a fourth to a third of the normal period, as tested by the standard period of Rieder's meal-time. By its influence in producing relaxation of muscular contractile vigour it increases the retardation of effective motility produced by pyloric spasm; and, in cases of organic obstruction, it increases the motile procrastination which results from pyloric stenosis by its lowering effect on the tonus of the muscular fibres of the coats of the stomach. The total result is that papaverin produces a retardation, of practically similar extent, of gastric motile activity in both pyloro-spasmus and pylorostenosis, and lasting for a corresponding period of time. Its therapeutic employment is, accordingly, indicated in pyloro-spasmus and in spastic obstipation, especially in combination with atropine.

Serum-therapy in the Toxicoses of Pregnancy.

Dr. Wolff has obtained conspicuously successful results in treatment of the pruritus and dermatoses of pregnancy by injections of serum—not of another gravid female, but of a healthy woman—taken at the close of an interval of 14 days after delivery. This therapeutic effect goes to prove that the serum of the post-partum patient in the early days after delivery must still continue to retain ferments which tend to disintegrate the molecules of the albuminous constituents of pathogenic organisms.

The Production and Course of Existence of Anti-bodies.

A communication which has just been published by Dr. Lüdke is devoted to demonstration of the fact that the complete periodic course of production of anti-bodies is definable in two anti-body types—agglutinin and hæmolysin. The three phases of the oscillation-curve of the existence of the anti-body—latency, growth, and disintegration—can be defined in all properly investigated cases. The duration of the period of latency or incubation depends on the method of application and special variety of antigen, its quality of virulence, and the previous condition of the animal experimented on. And it was shown by further investigation on the same lines, and comparison of results obtained with the data supplied by clinical observation, and pathological investigation of the results of the effects of the disease and of inoculation on the human organism, in way of modification of its tissues and fluids, that the period of latency noted in the course of laboratory experiments on animals corresponded, at all points, and in every aspect, with the incubation period in men who were the subjects of infection. In the course of convalescence there was noticeable an abbreviation of the period of incubation, and a higher elevation of the titration value of the anti-body. Dr. Lüdke demonstrates the form of the anti-body curves in numerous cases of experiment carried out on the lower animals, also those observed in cases of infected human beings. After discussion of the normal course and production of anti-bodies, the author traces the history of the formation and development of anti-stuffs under pathological conditions in anæmic, icteric and nephritic animals. In every one of these cases, the various individual phases of the formation of the anti-body repeated themselves—even in those in which the lesions were of the most severe type, the process of anti-body formation always retained its sovereign power of survival; the effective intensity of the resulting formation, which expressed itself in the titration value, alone appearing to undergo depression in such cases.

The Poisonous Miana Bug (Argas Persicus).

Lehmann has published an interesting communication on this recent addition to our armamentarium of entomological toxicology, of which he recently exhibited some examples to some of the scientific societies. It belongs to the tick group and is found in Persia. Natives do not seem to notice any effects of its punctures, but foreigners feel sharp pain at the time, and develop symptoms of illness afterwards, which may even end in death after the course of a few days of suffering. The symptoms are mainly gastric. The treatment is chiefly dietetic—by administration of very sweet articles of food. We are obviously concerned with intoxication by animal poison. The poison glands are yet unknown.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Professorship of Clinical Medicine in Edinburgh.

At a meeting of the University Court on the 20th, Dr. William Russell was appointed to the new Moncrieff Arnott chair of clinical medicine. Dr. Russell is at present the Senior Ordinary physician to the Royal Infirmary, and under the new arrangements was one of the senior lecturers on clinical medicine. He has had a very distinguised career, having obtained a gold medal for his thesis for the degree of M.D. in 1884, and the Cullen Prize of the Royal College of Physicians in 1893. He has lectured on the practice of physic for many years, and has taken a deep interest in the School of Medicine for Women, of which he is at present Dean. Dr. Russell was attached to the Royal Infirmary as pathologist for a number of years in the eighties, and in due course he was elected to the medical staff. He has always associated himself with any movement which has for its object the general welfare of the profession. He has held office in the British Medical Association, being President of the Edinburgh branch. He took a foremost part in organising resistance to the terms of the Insurance Act, and was a moving spirit in the creation of the Scottish Medical Insurance Council, of which he was chairman. When the *Scottish Medical and Surgical Journal* was founded in 1897, Dr. Russell was appointed its first editor, and under his guidance the journal prospered exceedingly. His principal contributions to medical literature are his work on "Arterial Hypertonus," a manual of physical diagnosis, in the authorship of which the late Dr. G. A. Gibson also participated; the section on arterial disease in Gibson's textbook of medicine; the article on "Vessels" in the "Encyclopædia Medica"; "Investigations into some Morbid Cardiac Conditions," and numerous contributions to periodical literature, chiefly on vascular and digestive disorders. Dr. Russell is held in high esteem by his colleagues in the College of Physicians, as is evidenced by the fact that he is a member of the Council of that body, and is their representative on the General Medical Council. He is also a Major in the R.A.M.C. (T.), Scottish 2nd General Hospital.

Murray's Royal Asylum, Perth.

The directors of this Asylum have appointed Dr. R. Dods Brown Physician-Superintendent of the Institution. Dr. Brown is at present Senior Assistant Physician at Morningside Asylum, where he has served both under Sir Thomas Clouston and Dr. George M. Robertson. He now succeeds Dr. Urquhart, who has resigned his office. In his last report, for the year ending March 31st, 1913, Dr. Urquhart states that the patients in the Asylum at the end of the year numbered 120; during the year there were 15 deaths. The average rate of admission is 33 per annum, and in 1912–13 exactly that number of patients were admitted. The number of curable patients was 12, of whom 10 recovered during the year. Twenty-one of the admissions had a bad heredity; in eight morbid heredity was denied. The percentage of deaths was 12.32, the average rate being about 6.23. The average age at death was 73 years, and the average duration of residence nine years. The high death-roll was ascribed to the effect of the inclement season on a community of aged persons.

Gartloch Mental Hospital.

The sixteenth annual report of this asylum, dealing with the year ending May 15th, 1913, has been issued. At the end of the year there were 389 male and 364 female patients in residence. The admissions numbered 235, the discharges 180, and the deaths 90. Twenty-two per cent. of the new patients were under 30, 46 per cent. between 30 and 50, and 32 per cent. over 50. Senile and paralytic cases are very numerous and make the ward work heavy. Owing to an accumulation of residual cases, troublesome and dangerous paranoiacs and epileptics are being crowded more and more closely together, hence the wards are less manageable than they used to be. The only way to improve this is to increase the accommodation, and H.M. Commissioners in Lunacy continue to draw attention to the narrow margin of vacant beds. At July 15th, 1913, there were no empty beds on the female side, and only 24 on the male side. This shortage of beds greatly increases the difficulty of proper supervision; if a patient falls sick he has to be sent to a sick room, and this may mean displacing a patient who ought still to be under observation. In view of these facts, Dr. Parker, the Superintendent, urges that there should be two new blocks for phthisis of 30 beds each. At present it is necessary to treat some males suffering from phthisis on the verandah of the male admission ward. The death-rate for the year was 11.5: of the 90 deaths 18 were due to general paralysis. Alcohol was the main determining cause of the insanity among the admissions; alone, or along with syphilis, it accounted for 20 per cent. The Wassermann test has been extensively carried out during the year. Of 213 admissions tested 30.9 were positive. Dr. Parker anticipates that the first effect of the Mental Deficiency Act will be to strain the present asylum accommodation by increasing the number of deficients. The report of the Commissioner speaks in high terms of the management of Gartloch, and approves of the arrangements being temporarily made by the District Lunacy Board to meet the demands on their accommodation.

Medical Candidates for the Glasgow Municipal Election.

The municipal elections are at hand, and in Glasgow some medical candidates are in the field. Dr. Edward McConnell, who is a bailie, has been for a considerable time in the Town Council, as also has Councillor Dr. James Erskine. The latter, whose term of office now expires, seeks re-election, but is opposed by another candidate. For the representation of Townhead Ward, a younger practitioner, Dr. P. Mackellar Dewar, has come forward to oppose the re-election of a labour representative. The return of Dr. Erskine and Dr. Dewar to the Council would make up the number of medical members to six—certainly not an over-representation of the profession in a body consisting of 113 members and having the care of a population of a million. Of the six referred to, four are engaged in panel practice under the Insurance Act.

BELFAST.

Royal Victoria Hospital.

At the opening of the winter session, a lecture was given by Dr. Rankin, Assistant Physician in Charge of the Electrical Department. After discussion the nature of the work in the wards and out-patient department, Dr. Rankin reviewed the various conceptions that had at various times been entertained on the nature of disease. He showed how these general conceptions influenced our attitude toward the ætiology, diagnosis and treatment of disease. After enumerating some of the latest discoveries in medicine and surgery, he went on to describe more particularly recent advances in electro-therapeutics. He mentioned the use of the X-rays and radium in the treatment of cancer, and concluded by predicting further advance and the increased importance of the electrical department of our medical school.

Mater Infirmorum Hospital.

A new department in connection with X-ray and Finsen light has just been established at the Mater Hospital. On the 23rd inst. the medical staff of the Hospital invited the practitioners of the district to an exhibition of the working of the new installation. There was a large response, and those present were much pleased with the display of the most modern X-ray work. The installation consists of a complete X-ray outfit and a quartz lamp for skin work. The X-ray outfit is one of the largest and most modern in the three kingdoms, and the staff and management of the hospital are to be congratulated on the possession of such an efficient addition to their armamentarium for the diagnosis and treatment of disease.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

INSANITARY FRANCE.

To the Editor of The Medical Press and Circular.

Sir,—Some weeks ago there appeared in your valuable paper some editorial paragraphs on this subject. These were followed by an important correspondence, in which I took a humble part. It may be hard to say whether this discussion of a subject rarely alluded to in French or English journals has had any effect in bringing about the result, but it is gratifying, at any rate, to note that a movement has been started which may in time lead to the drastic reforms in public hygiene called for throughout, in order to bring France in this direction up to the level of civilisation attained by her neighbours. The current French papers give an account of a meeting yesterday (October 15th) of 3,000 delegates from provincial towns to discuss the means of encouraging tourist traffic in France. M. Thierry, Minister of Public Works, presided. The Congress began by discussing the steps needed to improve the standard of country hotels, and to educate hotel keepers in the requirements of modern tourists. It was pointed out that the fact that in Paris and on the Riviera, the only parts of France at present largely visited by tourists, the hotels are mainly in the hands of foreigners, is proof that such education is needed. Hotel hygiene will occupy a good share of the attention of the delegates. This movement, whilst it must prove valuable in an educative way, will not suffice to advance very far the hygienic condition of the country generally, or to remove the shameful and damaging scandal of a death-rate so much higher than that of Great Britain and Germany. The hotels will no doubt in time be provided with closets which themselves will be ventilated and provided with flush-tank apparatus with an adequate supply of water. But if the soil pipes remain unventilated and discharging into foul cesspools or more foul sewers, and if these in their turn are allowed to pollute the smaller watercourses and bigger rivers, very little advantage is likely to accrue to the mass of native inhabitants or foreign sojourners on French soil. In my previous letters I dwelt upon the fact that the gross neglect of public hygiene constitutes a serious handicap to the prosperity of the French nation. It is to be hoped that the new movement which I now report may do something towards impressing this fact upon the leading statesmen who now control the destinies of their country.

I am, Sir, yours truly,
Anglo-Francais.

Boulevard des Capucines, Paris.
October 16th, 1913.

YELLOW *VERSUS* WHITE VASELINE IN THERAPEUTICS.

To the Editor of The Medical Press and Circular.

Sir,—We read with much interest the item in your issue of August 13th, 1913, entitled "Yellow *versus* White Vaseline," and should appreciate your affording us space in your publication for the following observations:—

(1) "Vaseline" is the registered trade mark of the Chesebrough Manufacturing Co., Cons'd., in the United States, Great Britain, and other countries, for use by it alone on products of its manufacture.

(2) We therefore assume your article refers to the white and yellow petrolatum jellies sold by this Company under its trade mark "Vaseline."

(3) There is little or no difference therapeutically between the white and yellow "Vaseline."

(4) From the white has been removed by filtration, not otherwise (as by acids and alkalies) more of the coloured matter—the oxidised carbon—of the crude petroleum, than from the yellow.

(5) Products from petroleum more or less resembling ours in appearance are made by chemical treatment,

and retreatment to wash out the remaining chemicals.

(6) These treatments are variable, unstable, and may be dangerous.

(7) Many of these products are mixtures of paraffin waxes and oils in varying proportions, are subject to separation of the wax from the oil, and retain, more or less, taste and odour of petrolatum.

I am, Sir, yours truly,
per pro Chesebrough Manfg. Co.,
Chas. F. Emery,
General Manager.

Holborn Viaduct, London.
October 23rd, 1913.

[The above communication should be of interest not only to dermatologists, but to the medical profession generally.—Ed. M.P. and C.]

NEW DERMATOLOGIAL SOCIETY OF LONDON. DISCUSSION ON LICHEN PLANUS.

To the Editor of The Medical Press and Circular.

Sir,—I did not receive for correction the shorthand reporter's notes of my remarks on lichen planus during the discussion on that affection which took place on October 9th. Consequently errors and an omission occurred which I should like to correct.

"Where the hair follicles were *well marked*" should read "*not* well marked."

"The lichen planus began *above* the sweat pore and duct" should read " . . . *about* the sweat pore," etc.

I mentioned that I looked upon the sweat apparatus as similar to the excretory organs of the kidney, and that probably the pathology of lichen planus had its counterpart in inflammatory disease of that organ.

I am, Sir, yours truly,
Alfred Eddowes.

28 Wimpole Street, W.
October 27th, 1913.

OBITUARY.

DR. J. D. SWALLOW, OF CLAPHAM.

At Clifton Lodge, Clarence Road, Clapham Park, on the 11th inst., Dr. James Dodd Swallow passed peacefully away, in his 78th year. The deceased was long a well-known and popular figure in Clapham, in the neighbourhood of which he had been practice for nearly 52 years. Born at Henley-on-Thames in 1836, he was first apprenticed to Mr. G. May, a Reading surgeon, after which he went to St. Thomas's Hospital, where he had a very distinguished career, taking his M.D. at St. And., and becoming M.R.C.S.Eng. and L.S.A.Lond. Dr. Swallow first set up in practice in Kennington Park Road, but removed shortly after to 343, Clapham Road, where he remained in practice up to within a week of his death. His loss will be felt deeply by all with whom he came in contact, for he was greatly esteemed on account of his sympathetic nature and kindness of heart. At one time he was reputed to possess the largest practice in South London, and amongst the appointments he had held were those of Surgeon to the Royal South London Dispensary, St. Martin's Hospital for Fistula, the Linen and Woollen Draper's Institution, and the London City Mission. He was greatly interested in medical charities and was Hon. Local Secretary of the Epsom Medical College and the Royal Medical Benevolent Fund. Dr. Swallow leaves a widow, three sons, and one daughter.

DR. A. B. CARPENTER, OF CROYDON.

We regret to announce the death of Dr. Arthur Bristowe Carpenter, M.A., M.B., L.R.C.P., eldest son of one of the most distinguished citizens of Croydon, Dr. Alfred Carpenter, which took place last week. He had suffered from bad health for the last two years, but bravely fought against pain and continued to practise. He had been seriously ill for six weeks, and was removed to a nursing home in the Dingwall Road, where he underwent an operation for an internal complaint on October 14th, and died on the 16th. In his school days at Winchester he gained a scholarship and afterwards a Winchester scholarship, and many other honours at New College, Oxford. He entered as a student at St. Thomas's Hospital, and had several appointments there, and then returned to Croydon and started a practice. He was a member for years of the committee of the Literary and Scientific Institute, also churchwarden of St. James's, and at one time a member of the old Croydon School Board, being first elected in 1891 and re-elected in 1894. He was in early days a good athlete, but his real hobby was bell-ringing, and for a year he was secretary of the Surrey Association of Bell Ringers. He leaves a widow and five children.

REVIEWS OF BOOKS.

DISEASES OF THE STOMACH. (*a*)

The fact that Dr. Einhorn's book has reached its fifth edition is proof of its continued utility to the profession. The present edition shows many advances on its predecessors, the most notable change being in the prominence given now for the first time to the uses of the X-rays in diagnosis. Dr. Einhorn is a clear thinker, and is able to put his teachings in the most easily intelligible form. His chapter on the methods of examination should be studied by every physician. Before proceeding to discuss the more complicated methods, he tells clearly what should be done by the more simple methods of interrogation, inspection, palpation and percussion. It is surprising how much can be learned from a careful and intelligent use of these methods. In his discussion of the causation of gastric ulcer, the author inclines to accept the recently fashionable view of the importance of hyperacidity as the main factor. Like other holders of this theory, he fails to make any suggestion as to how hyperacidity can bring about an ulcer. The fact that hyperacidity is frequently present in cases of gastric ulcer does not give us much help when we bear in mind that, as Dr. Einhorn himself says, gastric disorders are accompanied by hyperchlorhydria in more than one-half of the number of cases of digestive affections. It is right to add that the author maintains that gastric ulcer may occur without hyperacidity. In discussing the treatment of perforated gastric ulcer, Dr. Einhorn refers only casually to surgical treatment—"resort has been lately had to laparotomy." Surely it is recognised by now that surgical treatment is not a matter of choice in case of perforation. Dr. Einhorn gives a useful outline of diet for use in cases of gastric ulcer. The quantity of fluid food he gives in the early stages—viz., nearly two quarts, chiefly milk, in doses of five ounces every hour, seems to us excessive, but no doubt it has given good results in Dr. Einhorn's hands. The book as a whole is thoroughly satisfactory, and should be on every physician's shelves.

CLIMATOLOGY AND MEDICINE. (*b*)

The contents of these lectures are, of course, already known to most of our readers. But the subject is one which must ever retain its freshness and vital importance. The principal aim of the author has been threefold—to show the serious effects of general negligence of climatology; to insist on recognition of the principle of approximate isolation of influences; and to emphasise "the absence of any valid evidence that altitude *per se* affects the prevalence of phthisis." The author's general state of mentality in the connection may be approximately gauged by some experienced readers from the following sentences (found on page 20): "What right have we at present to believe that the

(*b*) "The Plaoe of Climatology in Medicine." Being the Samuel Hyde Memorial Lectures, read before the Section of Balneology and Climatology of the Royal Society of Medicine, May 20th and 21st, 1913. By William Gordon, M.A., M.D.Cantab., F.R.C.P.Lond., Physician to the Royal Devon and Exeter Hospital, etc. London: A. K. Lewis. 1913.

methods of open air, graduated exercise, and tuberculin administration cannot be aided by judiciously selected climates? It may be that they cannot. But it is wholly unjustifiable to assume it. . . . . 1858 is no doubt a very long while ago, and since then Koch's discovery of the bacillus of tubercle has drawn a barrier of demarcation across the history of phthisis investigation, so that all antecedent statements require investigation." The author's views on bacteriological pathology are very obviously "orthodox." Whether he is truly "scientific" in his notions of climatology, and the application thereof to therapeutics, is a question which must be variously answered; according to the scientific attainments and critical capacity of the reader.

THE HEALTHY MARRIAGE. (*a*)

Believing, as does the author of this little work before us, that the married state is the proper social setting to the natural functions of men and women, he has succeeded in producing a popular manual which should be consulted by every newly-married woman. Interestingly written, in not too technical a style, Dr. Wrench at once appeals to the reader's intellect and leads up by degrees to a homely and helpful explanation of all the phenomena accompanying normal pregnancy, childbirth, and the menopause. We have rarely come across a book in which the ideals of marriage are held up in so exalted a fashion from the sociological and physiological aspects as the one under consideration. As the author wisely remarks, "A sound physiology is the rock upon which to build up firm wedded happiness." Given this desideratum, the rest follows naturally, and the neurasthenic or hysterical disposition will be prevented from developing. In the twenty-two chapters are discussed every topic of vital interest and importance to the married woman. Dr. Wrench is evidently no lover of "tube" railways, for in lamenting the want of exercise from which so many women suffer he desciibes those who work in towns as being "hurtled through an iron bowel buried deep in the earth, with air pumped down to them and the light of the metal filament overhead," until, having arrived at their place of business, their occupation only too often "bends and sacrifices the organism to its peculiar speciality." As might be expected from the author's special experience, the directions given for the preparation of the lying-in chamber, the management of ordinary labour in the absence of skilled medical assistance, are all thoroughly sound and practical. In short, we have no hesitation in recommending this book as an indispensable guide to the prospective mother.

ASTHMA, AND ITS RADICAL TREATMENT. (*b*)

In our present lack of knowledge of satisfactory treatment of the group of symptoms classed together as asthma, any book which helps to clarify our ideas and to indicate a plan of procedure "which fifteen years of experience have proved to be increasingly successful, and which vindicate the view adopted as to the nature of the disease," is likely to be read with considerable interest, even if the beliefs contained therein shall not chance to find immediate and universal acceptance. That immediate belief will follow is hardly to be expected of an attitude of mind balanced and scientific, but the reasons for the author's views will be found to dovetail very closely with our previous knowledge, and, if such success attends the treatment of the patients of other doctors, as is asserted by Dr. Adam in his own experience, then indeed can he claim to have advanced medical science in the amelioration of this widespread and distressing malady. Put shortly, Dr. Adam believes the asthmatic paroxysm to include hyperæmia of the mucous membrane and spasm of the bronchioles, both conditions being the result of toxæmia. According to the kind and extent of the latter, hyperæmia, he says, may vary from that of the recurrent "bronchitis" of children, to "angioneurotic and acute pulmonary œdemas." As regards the importance of the nasal factor, in asthma one is inclined to agree with the author that the value of proper nasal treatment cannot be gainsaid, but that it should be secondary to treatment of the primary toxæmia. The proof of this contention is that asthma can remain unaltered even after extremely drastic nasal operations have been carried out, whilst it promptly clears up on simple anti-toxæmic treatment.

The assumption that asthma is due to a definite toxin causing bronchial spasm, similar in action to muscarin and originated in the intestinal canal appears highly probable, for experimentally it has been found that poisons arise with powerful actions on the nervous system either by the agency of bacteria or through normal enzymatic metabolism of proteins. Normally these are stopped in the intestinal wall and liver, and are antagonised by atropin. Further evidence is statistical and clinical.

Prognosis, according to Dr. Adam, is very favourable if combined nasal and anti-toxæmic treatment be adopted, 76.4 per cent. of cases of *more than ten years standing* being "cured" and 21.3 per cent. improved. The last chapter on treatment is especially to be recommended, whilst the tenor of the whole work encourages the profession to proceed along such hopeful lines.

THE NATURE OF WOMAN. (*a*)

Never was there greater need for clear thinking on what is roughly termed the woman's movement than to-day. Women are becoming more and more eager in claiming a larger share than formerly in political, industrial and social work. That they will do so is certain. That they are adopting methods towards that end of which many people disapprove is irrelevant. The important thing is to have a clear idea of the part that the feminine can best play in these several spheres. That is to say, to learn in advance for what part of the world's work woman is best fitted. What part can she, in fact, play better than man? What part can she alone perform? The essential argument of Mr. Tayler's book, as we understand it, is that woman has fundamental differences from man, as far reaching in mental quality as in physical structure and physiological function. In this we cordially agree, and it is a point too frequently overlooked. Many of the so-called feminists base their arguments for equality with man on an assumed identity of nature, not seeing that the strongest argument for woman's freedom from undue control is that she may be free to develop her own individuality. For emphasising this essential difference of nature we are grateful to Mr. Tayler, even if we do not go with him in his views as to the exact lines on which woman should develop. We cannot regard her as a mere home-maker, even if we agree that her work in the home is the highest of which woman is capable. It seems to us that Mr. Taylor is so irritated by the illogical and short-sighted views of various feminist writers, that he limits his own outlook too narrowly. The truth is that lines of development cannot be accurately foretold; we may, however, form a shrewd judgment of what lines are impossible. An instance of Mr. Tayler's curious perversity is to be found in the first sentence of his book, where he tells us, first, that "the study of sex is primarily a human one," and next, that "sex specialisation and intensity have reached a higher stage in the human species than elsewhere." The first statement reverses the process of evolution, and is, moreover, contradicted by the second, which is itself, we think, untrue. Nevertheless, Mr. Tayler is to be congratulated on having written a thoughtful and interesting book, and one which contains much truth which is too often forgotten.

(*b*) "Asthma, and Its Radical Treatment." By James Adam, M.A., M.D., F.R.F.P.S. Pp. 179 and index v. 1913. London: Henry Kimpton.

(*a*) The Nature of Woman." By J. Lionel Tayler, M.R.C.S., L.R.C.P. Pp. 186. London: A. C. Fifield. 1912.

LITERARY NOTES.

In the October number of the *Medical Chronicle*, Dr. Judson S. Bury, it new editor, states that, in addition to the ordinary features of the journal, references will be given to medical matters in general literature, as well as a number of short extracts from medical and other publications. A warm tribute is paid to the work of the former editors, Drs. Brockbank, and Tylecote. We wish our contemporary continued prosperity under its new rule.

* * *

The "plans for advance" disclosed in *Mercy and Truth*, the organ of the C.M.S. Medical Missions, concern chiefly the supply of living agents and the provision of hospital buildings. It is evident that great care has been expended on the inquiries which have resulted in these proposals, and truly, "the prospect of advance is one which cannot fail to inspire with new hope all who are helpers in the Foreign Missions of the Church." Dr. Lilias Blackett gives the story of a cold weather tour in the Dera Ghazi Khan district.

* * *

The new volume for 1912 of Merck's Annual Report (Vol. XXVI., 1913) is a most useful compendium of modern pharmacology. All the latest advances in pharmaceutical chemistry and therapeutics are dealt with upon the lines of previous issues. An interesting symposium of lecithin occupies the first seventy pages, which is most opportune, seeing how greatly lecithin has come to the front of late in medicine. Many new preparations are also described, together with a succinct *résumé* of the work done during the past year in connection with other newer remedies. An immense amount of information is contained within the 1913 report which cannot fail to be useful to the busy practitioner.

* * *

The second issue of the *British Journal of Surgery* (price 7s. 6d. per copy, or 25s. per annum) fully maintains the high standard of its predecessor. The frontispiece is a portrait of John Hunter, who is described as working the raw material of scientific surgery. Sir John Bland-Sutton writes on the surgery of the spleen. Mr. F. W. Goyder, of Bradford condenses his Jacksonian Essay on the Embryology and Treatment of Cleft Palate into an instructive paper. Recent advances in the surgery of the lung and pleura are dealt with by Mr. H. Morriston Davies. Mr. Andrew Fullerton (Belfast) describes a series of 48 successive nephrectomies with four deaths. An interesting case of sellar decompression is reported by Professor William Thorburn (Manchester), while a review of the more important factors involved in operations upon the hypophysis cerebri is contributed by Mr. Manfred Moritz (Manchester). A good account is given of a visit to Sir Arbuthnot Lane's surgical clinic at Guy's Hospital and to that of Dr. Lambotte at Antwerp.

MEDICAL NEWS & PASS LISTS.

The International Tuberculosis Conference.

The German Empress attended the opening meeting of the International Tuberculosis Conference, which was held on October 23rd, in the Lower House of the Prussian Diet in Berlin. Dr. Franz Bumm presided. The Conference was welcomed by the Secretary of State for the Imperial Ministry of the Interior, Dr. Delbrück, who observed that the Conference was meeting at the place where the international organisation was founded exactly eleven years ago under the patronage of the German Empress. It now embraced the whole world, and united the nations in a common labour for humanity. Speaking of the fight against tuberculosis in Germany, Dr. Delbrück said that there were now 147 sanatoria, with 15,278 beds. There were 103 institutions, with more than 9,000 beds, for children threatened with tuberculosis, 114 forest sanatoria, and 17 forest schools. He observed that England held the lead in the matter of notification, and referred to the new movement in Germany for the isolation of cases in an advanced stage of the disease. This point was endorsed by the Medical Officer of Health for Berlin, who announced that a special tuberculosis hospital, with 1,000 beds, is to be built here.

Of the British representatives, Dr. Barty King, of London, Dr. Nathan Raw, of Liverpool, and Dr. Shennan, of Edinburgh, were present. The subjects discussed were tuberculosis and mankind, and the surgical treatment of tuberculosis. Papers were read by Dr. Louis Rénon, of Paris, about the artificial pneumo-thorax, and by Professor Brauer, of Hamburg, who is a pioneer in the surgical treatment of pulmonary tuberculosis.

Death of a Famous French Surgeon.

News has been received of the sudden death of Dr. Lucas Championnière, the well-known surgeon, which took place suddenly on the 22nd inst, whilst reading a paper before a committee of the Institut de France. He was famous as having been the first to introduce into France the antiseptic method in surgery, which he had learned from Dr. Lister, as far back as 1868. He met Dr. Lister in Scotland in that year, when the new methods in surgery had not yet been generally accepted. He was thus the most active agent in France of the transformation which has changed the whole surgical art in recent times. He was also the author of various works on the radical cure of hernia and surgery of the brain, and on the treatment of fractures by massage. He was to have made a communication to the Institut on the 25th inst., and he was reading the text before the committee when he suddenly fell back in his chair and expired. His death was due to an embolism.

London Medical Referees.

It is reported that the appointment of Medical Referees in London has already resulted in the detection of many cases in which insured persons under the Act were able to work while claiming sickness benefit. At last week's meeting of the London Insurance Committee at Spring Gardens, Mr. Fred Coysh reported that they had had 389 applications for the services of the medical referees and 221 reports had already been furnished from approved societies in respect of those cases. Of the first 255 cases the doctors reported that 108 were able to work, 86 were incapable of work, and the other 61 had chosen between discretion and valour and declared "off." Thus, 34 per cent. of the cases submitted to the referees remained upon the approved societies' deposits at the present time.

The Guild of St. Luke.

The annual service of the Guild of St. Luke for Medical Men was held on October 21st at St. Paul's Cathedral. The preacher was the Rev. Canon Arnott, F.R.C.S., Rector of Beckenham, whose remarks were characterised by practical common-sense and devout spirituality. He pleaded for a greater co-operation between the clergy and medical men, for there was no real need for the subtle antagonism that sometimes existed between them. The first lesson was read by Sir Dyce Duckworth, Bart., M.D. (Vice-Provost of the Guild), while the second was read by the Rev. H. Kirkland-Whittaker, M.D., Secretary. There was a good attendance of members and friends.

Medical Sickness and Accident Society.

At the last meeting of the Executive Committee, held a few days since, Dr. F. J. Allan in the chair, the claim account presented showed a slight margin against the Society, and from figures to hand it would appear that the claims will be heavy for the whole year. New proposals were up to the average, and the proposals for additional benefits show a steady increase. This being the quinquennial valuation year, the results are awaited with a good deal of interest, as it is the sixth quinquennial valuation since the inception of the Society in 1884. In spite of the serious depreciation of gilt-edged securities in which a large part of the Society's Funds are invested, and the consequent writing-down of these, it is expected that a substantial surplus will be shown this year as in the previous reports. Inquiries have been directed to the office as to whether dental surgeons are eligible for membership. There are already a large number in the Society, and members of the dental profession who wish to join are asked to write for a prospectus to the Secretary.

Medical Man found Dead.

Dr. Horace Dimock, the special insurance panel doctor at Wisbech, who was charged with criminal libel and was remanded on bail on Friday last, was found dead in his bed on October 27th.

On Saturday night there was the usual crowd of patients at his surgery, the waiting-room and hall being full, while others waited outside. He told one patient to see him again on Tuesday. On Sunday he visited his patients on his motor cycle, and returning to his home at Stretham, near Ely, at nine o'clock, he went to bed, as he had had no sleep for three nights. On the 27th inst. his sister found him dead in bed.

Dr. Dimock, who was M.B., B.C.Cantab., and M.R.C.S., L.R.C.P., was formerly resident anæsthetist at St. George's Hospital, and Senior House Surgeon at Addenbroke's Hospital, Cambridge. He went to Wisbech from Ely early in the present year to complete the panel of doctors under the Insurance Act.

Society of Apothecaries of London.

At a meeting of the Board of Examiners the following candidates, having passed the necessary examinations, received the L.S.A. diploma of the Society, entitling them to practise Medicine, Surgery, and Midwifery:—W. Alcock, C. Duncan, S. E. Murray, W. E. Masters, and W. V. Tothill.

The Royal College of Physicians Ireland.—Election of Officers.

At the stated annual meeting of the President and Fellows of the Royal College of Physicians of Ireland, held on St. Luke's Day (the 18th inst.), the following officers were elected for the ensuing year:—

President: Dr. Charles E. Fitzgerald; Vice-President: Dr. James Craig.

Censors: Dr. James Craig, Dr. T. G. Moorhead, Dr. A. Nixon Montgomery, and Dr. T. Henry Wilson.

Examiners for the Licence to Practise Midwifery: Dr. Hastings Tweedy and Dr. Gibbon FitzGibbon.

Additional Examiners to take the place of an absent Censor or Examiner: Medicine, Dr. Parsons; Midwifery, Dr. Norman Holmes; Medical Jurisprudence and Hygiene, Dr. H. T. Bewley.

Supplemental Examiners under the Conjoint Examination Scheme: Biology, Dr. MacDowel Cosgrave.

Chemistry: Dr. Edwin Lapper and Dr. Ninian Falkiner.

Physics: Dr. Harvey and Dr. Rowlette.

Pharmacy, Materia Medica and Therapeutics: Dr. Travers Smith and Dr. D. J. O'Connor.

Physiology: Dr. H. C. Earl.

Pathology: Dr. F. C. Purser.

Medicine: Dr. J. F. O'Carroll and Dr. H. C. Drury.

Hygiene and Forensic Medicine: Dr. W. A. Winter.

Extern Examiners for the Conjoint Preliminary Examination: Languages, Mr. E. H. Alton, F.T.C.D.; Mathematics, Mr. R. A. P. Rogers, F.T.C.D.; Irish, Mr. Edward de Valera, B.A., R.U.I.

Examiners for the Diploma in Public Health: Chemistry, Professor E. Lapper; Hygiene, D. F. C. Martley; Bacteriology, Dr. H. C. Earl; Meteorology, Dr. Matson.

Examiners for Membership: Clinical Medicine, Dr. James Craig, V.P., and Dr. George Peacocke; Practice of Medicine, Dr. T. G. Moorhead and Dr. Martin Dempsey; Pathology and Bacteriology, Dr. H. C. Earl and Dr. A. C. O'Sullivan; Midwifery and Gynæcology, Sir William Smyly and Sir Arthur Horne.

Representative on the General Medical Council: Sir John Moore.

Representatives on the Committee of Management: Dr. Walter Smith, Sir John Moore, and Dr. T. P. C. Kirkpatrick.

Treasurer: Dr. H. T. Bewley.

Registrar: Dr. T. Percy C. Kirkpatrick.

Librarian: Mr. R. G. J. Phelps.

Law Agents: Messrs. S. Gordon and Sons.

Land Agents: Messrs. Townsend.

Architect: Mr. A. E. Murray.

Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and Royal Faculty of Physicians and Surgeons of Glasgow.

The quarterly examinations of the above Board, held in Edinburgh, were concluded on the 25th inst., with the following results:—

First Examination.—The following candidates passed the first examination:—Joseph Michaelson, Andre A. Lamaletie, Venkatasubba Mahaderan, Clifford Pullan, William Jackson, James H. Brown, Alexander Morrison, and Sengarapallai Ponniah. Six passed in Physics, three in Biology, and three in Chemistry.

Second Examination.—The following candidates passed the second examination:—Hugh G. Anderson, James S. Durward, Clarence J. Middleton, John H. Bain, Harry Ellison, Owen G. Evans, and Victor A. Rankin. Two passed in Physiology.

Third Examination.—The following candidates passed the third examination:—Cawton F. Pereira, Joseph V. Duffy, Alexander G. McKee, William MacLeod, Allan G. Bee, William H. Wray, Thomas W. Drummond, John K. Garner, and Robert C. W. Spence. Three passed in Pathology and five in Materia Medica.

Final Examination.—The following candidates having passed the final examination were admitted L.R.C.P.E., L.R.C.S.E., L.R.F.P. and S.G.:—Joseph B. Wilman, John B. Aickin, Charles S. Ogilvy, William Bannatyne, Emma C. R. Fisher, Solomon D. Bridge, Bickford J. Hattam, Winnifrid M. Doran, Michael P. Power, John W. McCagie, Venkatasubba Mahadevan, Charles Dolan, Harold E. Rose, Robert H. Thomson, Robert E. N. Martyn-Clark, John N. Clark, Michael V. Walsh, and John R. Smith. Two passed in Medicine, three in Surgery, seven in Midwifery, and fourteen in Medical Jurisprudence.

Conjoint Examinations in Ireland.

The following candidates have passed the First Professional Examination of the Royal College of Physicians and the Royal College of Surgeons, October, 1913:—

J. Cusack, L. Finnegan, P. J. Flood, W. F. Moorhead, W. H. Pierce and W. H. Sexton.

The following candidates have passed the Preliminary Examination of the Royal College of Physicians and the Royal College of Surgeons, October, 1913:—

J. J. Brennan (passed with honours), M. C. Albuquerque, J. T. Alcock, E. S. Becker, V. A. Carroll, S. Conway, T. H. Cooper, R. J. Cussen, J. Denaher, B. Epstein, J. A. F. Flynn, S. J. Halpin, J. A. Hamilton, W. R. Henry, N. L. C. Irwin, P. McAndrew, P. J. McGing, C. McGlade, E. J. Magner, M. R. Morris, C. J. H. Mouritz, G. O. Nightingale, H. O'Neill, J. C. Rowan, V. E. Stack, P. G. L. W. Suys, J. F. Thornton, R. Walters, F. J. Walsh, and R. P. Williams

Intending medical students are required to register their names at once, as the lectures of the new session are now in progress.

Among the names added the other day in congregation to the list of benefactors of the University of Oxford was that of Dr. Theodore Williams.

The Chelsea Hospital for Women has received a grant of £500 from the Trustees of the Zunz Bequest. This donation is additional to the Trustees' promise of £10,000 towards the Rebuilding Fund.

Dr. and Mrs. C. H. Wise, who have recently left Walthamstow for the South of England, were the recipients the other day of a handsome presentation as a token of the esteem and respect in which they have been held by the inhabitants during their thirty years' residence in the district.

Summary of Recent Medical Literature English and Foreign.

Specially compiled for The Medical Press and Circular.

Emptying the Uterus as a Method of Treatment of Eclampsia.—Peterson (*Amer. Jnl. of Obs.*, lxviii., 2) has collected statistics of a large number of cases from various clinics, and claims that these show that prompt delivery gave a maternal mortality of 15.9 per cent., as compared with a maternal mortality of 28.9 per cent. when the delivery was long delayed. When the uterus is emptied immediately or very soon after the onset of the first convulsion, the maternal mortality is still lower. Before 1900 a large group of cases show 5 per cent. in favour of the conservative method of treatment, but from 1900 to 1912, on account of better and more prompt obstetric surgery the figures are reversed, and show that the mortality is lower by 4 per cent. after the radical as opposed to the conservative treatment of the complication. Therefore the treatment of ante-partum eclampsia should consist of emptying the uterus as quickly as possible after the onset of the first convulsion. The operative procedure which will empty the uterus the quickest with minimum trauma and shock to the eclamptic mother and child should be selected. The tables also show that the operative treatment has reduced the fœtal mortality. F.

The Medical and Surgical Treatment of Eclampsia. Zinke (*Amer. Jnl. Obs.*, lxvii., 6), from a review of the reported cases, is compelled to disagree with those who hold that the immediate emptying of the uterus is the best and only treatment for eclamptic convulsions and that it has reduced the mortality of the disease. He claims that the operative treatment has raised the maternal mortality by 1.75 per cent. above the average mortality obtained under various methods without hysterotomy. Cæsarean section gives a much higher mortality, according to the list of cases collected by Moran, and although the report is stated to show a steady improvement, the author cannot appreciate it. The absolute disregard for medical treatment in these cases is as flagrant as is the advocacy of surgical intervention as the only measure of relief. In the management of eclampsia much more good is to be obtained through intelligent medical care than some are willing to admit. The treatment of eclampsia on medical lines, as advocated by the author, is fully described. It is divided into prophylactic, (*a*) as applied to pregnant women, and (*b*) after the appearance of symptoms. Under the former head he advises milk diet, catharsis, hot baths, fresh air in abundance, gentle exercise, calisthenics and massage, suitable dress, sleep and rest in bed; the curative treatment deals with the control or abbreviation of the convulsions by the use of veratrum viride and the employment of bleeding in suitable cases; the use of chloroform is questionable, and chloral has been disappointing. The use of normal saline by rectum and hypodermoclysis is strongly urged, and oxygen inhalation is said to be of value. If the patient is at the end of the first stage of labour, and then only if the symptoms are grave, forceps may be employed to terminate labour. F.

Indications for Abdominal Cæsarean Section.—Peterson (*Surg., Gyn. and Obs.*, xvii., 2) in a short paper divides and considers the indications for Cæsarean section under three heads—(1) obstructions to labour, which include contracted pelvis, obstructions by tumours, stenosis of cervix or vagina, and miscellaneous conditions, such as ventrofixations, large size of child; (2) uterine hæmorrhages; (3) constitutional crises, eclampsia. In dealing with eclampsia, he says "that for those who do not believe in the immediate emptying of the uterus as soon as the patient has been seized with convulsions, neither abdominal nor vaginal Cæsarean section are ever indicated," but that "the majority of obstetricians" do believe in this, and therefore with eclampsia in a case with contracted velvis, and which has not been infected by manipulations or repeated examinations Cæsarean section is indicated. He concludes by saying that he is tabulating the results of 425 cases of eclampsia treated by Cæsarean section, 317 since 1900, and performed by over 200 operators. "The maternal mortality for the total number is 31.9 per cent."; of those treated "since 1900 it is 31.8 per cent." This reduction is produced by the operations being performed after what the author terms the beginning of the "aseptic era," and may therefore be considered due to aseptic *technique*. The 50 per cent. mortality is ascribed to errors in the selection of cases, because many were subjected to operation when they were hopelessly septic." "In 245 cases where there was no sepsis, or very little chance of sepsis prior to operation, the mortality is only 24 per cent." The infantile mortality for 317 cases is 5.5 per cent., and where the operations were performed after from one to five convulsions was further reduced to 3.7 per cent. From these statistics the future report should be interesting as showing how statistics can be made to support a theory in spite of figures. It is doubtful if any institution or any individual series of cases of eclampsia could be found which gives a mortality of 48 per cent. from any other line of treatment, and even taking the selected cases, 245 in number, which were evidently operated upon early, the probability is that even if the patients were left with no other treatment than starvation and a competent attendant, who would prevent their suffocating during the convulsions, the maternal mortality would not be much if any higher than 24 per cent. These statistics are particularly interesting when taken with the paper by Zinke previously summarised in this number, and in which this matter is touched upon. Peterson ends his paper by saying: "At least, the statistics in over 400 cases have shown beyond a doubt that no one is justified in dismissing the treatment of eclampsia by abdominal Cæsarean section with a short statement that the mortality is so high as to make it an unjustifiable operation." It is to be asked what mortality will make an operation unjustifiable. E.

Extra-uterine Pregnancy and Its Subsequent History.—Williams (*Amer. Jnl. Obs.*, lxvii., 6), from a study of 147 cases, reports the following facts:—Nineteen per cent. occurred in primiparous women; 8 per cent. were illegitimate pregnancies; 30 per cent. had a previous history of abortion; and 28 per cent. were preceded by premature confinement. The average interval after a uterine pregnancy until the extra-uterine pregnancy developed was 45 months. Recovery was noted in all the 17 cases operated upon during shock. Seven cases subsequently developed extra-uterine pregnancies at an average interval of 24 months. Thirty cases did not develop any subsequent pregnancies, while 39 intra-uterine pregnancies have developed subsequently, 28 ending at term and three being still pregnant. F.

Esthiomène or Lupus Vulvæ.—Kurz (*Jnl. Obs. and Gyn. Brit. Emp.*, xxiii., 6), from an analysis of six cases studied and reported, and the vast amount of literature published on the subject, concludes that this condition is a tertiary syphilitic manifestation, and that the syphilitic virus is the sole cause. The grounds upon which he forms this conclusion are, that the poor and neglected furnish the majority of cases, and servants, wives of soldiers and sailors are amongst the most frequent victims. Sterility, relative or absolute, is common. The age and period of occurrence in the cases reported varied from 20 to 50 years, but an old syphilitic history was suggested in all. In most cases some other indication of syphilis was present, and the condition might persist and progress without producing any marked change in general health, even after many years' duration, and might cause very little inconvenience. The presence or absence of enlarged inguinal glands does not influence the diagnosis. They might in early cases be syphilitic and in late cases septic in origin. The chronicity of esthiomène is a significant feature. In no other ulcerative condition is the history so long and so little disturbing in its effects. After a great many years it may cause death through malnutrition or toxæmia arising from fistulous burrowings. The condition does not always respond to anti-syphilitic treatment, but this depends on the duration and nature of the burrowings of the ulceration; early cases do respond, but old-standing ones do not. The cases respond to anti-syphilitic treatment combined with surgical methods and cleanliness and feeding. Histologically, esthiomène tissues are gummatous; they undergo the usual process of necrosis and cicatrisation. (A very full bibliography is given.) F.

Menstrual Molimina.—Chisholm (*Jnl. Obs. and Gyn. Brit. Emp.*, xxiii., 6), from inquiries among a number of adults engaged in various occupations, draws the following conclusions, which have been compared with facts previously collected from inquiries made amongst a number of young girls. Among adults the cases of disturbance at the menstrual periods are many more than among adolescents. Passive hyperæmia of the pelvic organs appears to be the cause of much local pain. This is relieved in the majority of cases in the first day after onset of menstruation. Unhealthy hygienic conditions and mode of life contribute to lowering the general nervous system, so that pain is readily felt, and a habit of pain at the periods is formed. Nervous symptoms, reflex and vasomotor, are often associated with secondary menstrual discomfort. Except in a small minority, this menstrual disturbance does not affect the woman's capacity for carrying on her ordinary work. Any development of menstrual pain shows a pathological condition whose cause, whether local or general, should be investigated and treated before the discomfort becomes established as a regular habit. F.

The Elastic Area in the Isthmus of the Uterus a Positive Sign of Pregnancy.—Ladinski (*Amer. Jnl. Obs.*, lxviii., 2) says that he has invariably found in early uterine pregnancy a circular area situated in the median line of the anterior surface of the body of the uterus, just above the junction of the body and cervix, that is, at the isthmus of the uterus, which varies in size according to the duration of pregnancy, and offers to the palpating finger the distinct sensation of elastic fluctuation. It can frequently be made out as early as the fifth week, when the area is only the size of a finger tip, and can always be felt in the sixth week. The area varies in size in a crescentic manner, and extends upwards towards the fundus until the third month, when nearly the entire anterior surface of the uterus presents a fluctuating cystic feel to the examining finger. The sign is not to be confused with Hegar's sign of softening, thinning and compressibility of the entire lower uterine segment. The author claims for his sign earlier appearance, constant and invariable pressure, greater ease and facility in detection over Hegar's sign, which would warrant general acceptance. The explanation of the cause of the change is not definite, but it is suggested that it is due to a hypertrophic process involving not only the muscle fibres and connective tissue, but especially the lymphatic and vascular structures of the uterus. F.

Vaccines in Enteric Fever.—Randolph (*New York Med. Journ.*, September 6th, 1913) records the result of his experience in treating enteric fever by vaccines. The patients treated may be divided into four groups; (1) those in whom the treatment was begun early in the infection; (2) those who had been ill for ten days or more; (3) terminal cases; (4) patients suffering from relapse or delayed resolution. The vaccine given was the same as that used by the United States Army for prophylaxis against typhoid fever. There was considerable variation in the dose given, as Dr. Randolph was trying to find out the best method of giving it. The vaccine is supplied in one c.c. ampoules, each containing one billion bacilli, and in his more recent cases Dr. Randolph has been using one-third of a c.c. for each dose. Three days' interval was generally allowed between each dose, but it is suggested that perhaps two days' interval would be more satisfactory. The general reaction following the injection of the vaccine varied a good deal. In the height of the disease a febrile reaction was not produced, but later on, as the temperature began to fall, the injection was generally followed by a sharp increase of fever, which lasted for from twelve to twenty-four hours. Patients in the stage of delayed convalescence or relapse exhibited a much sharper reaction, both local and general, than have those in the acute stage of the primary infection. Dr. Randolph admits that the number of the cases he has recorded is too small to enable him to draw any useful generalisations from his results, but he has a strong clinical impression that the vaccine treatment had a beneficial effect in the acute stage of the fever, and that this effect was better the earlier the administration was begun. All his patients expressed themselves as feeling better after the administration of the second dose of the vaccine. K.

Treatment of Pneumonia by Means of Specific Serums.—Cole (*Journ. Amer. Med. Assoc.*, August 30th, 1913) gives the following summary of his conclusions on the treatment of pneumonia by specific serums:—Antipneumococcus serum, in order to be effective, must be given early and in large amounts. Since pneumococci, so far as their immunity properties are concerned, are divided into distinct groups, it is necessary in each case to administer the serum active against the group to which the organism infecting the patient belongs. Highly active serums against two groups of pneumococci have been obtained, and treatment has been carried out in a small number of cases. The effect in these cases has been favourable, and the mortality has been very low. In judging of the value of serums, however, other facts are considered of more importance, namely, first, that bacteria in the blood are destroyed; and second, that immune substances, which ordinarily appear in the blood about the time of crisis, appear in the treated cases very soon after the administration of the serum. Lastly, there is some experimental evidence that part of the action of the immune serum may be antitoxic. K.

The Position of the Stomach in Children.—Sever (*New York Med. Journ.*, September 20th, 1913) has made an investigation of eighty-three averagely developed children to determine the normal position of the stomach. He concludes that it is usually situated much lower than one had previously suspected, and that it is not unusual to find the stomach at or below the crests of the ilium. The children were healthy and showed no symptoms of disorder as far as their digestive apparatus was concerned. In the majority of the children the stomach was large and either of the horizontal or of the "sink drain" type, while the so-called "cow's horn" stomach was rare. K.

Congenital Hypertrophic Stenosis of the Pylorus.—Mixter (*Bost. Med. and Sur. Journ.*, August 28th, 1913) records an invesigation into this condition, from which he draws the following conclusions:—An early diagnosis is the most essential factor in lowering the mortality from this disease. The bismuth X-ray will conclusively demonstrate the presence of pyloric obstruction. In any patient in whom careful medical treatment has failed to check the vomiting and progressive loss of weight, and where a pyloric obstruction can be demonstrated by X-rays, even if the differential diagnosis cannot be definitely made between hypertrophic stenosis and pylorospasm, exploration should be advised. X-ray photographs taken at varying intervals after operation show the pyloric obstruction to be a permanent condition, and in the patients studied the spasm was a factor of no importance in the obstruction. In true stenosis, surgery offers the only hope of cure. An infant develops normally after a posterior gastro-enterostomy. K.

NOTICES TO CORRESPONDENTS, &c.

☛ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial,* and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office, 8, Henrietta Street, Strand; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

DR. T. M. (N. Wales).—Since the establishment of the British Goat Society, which publishes a monthly register and herd-book, a great deal of useful information has been collected regarding the breeding of goats. It is well known, of course, that goat's milk is a safe food for consumptives, being preferable in many ways to cow's milk.

MR. W. JOHNSON (Ealing, W.).—According to recent returns, compensation was paid, in 1912, in 3,599 cases of death and in 424,406 cases of disablement under the provisions of the Workmen's Compensation Act and Employers' Liability Act. The average payment in each case was £158, and in case of disablement, £6 3s.

M.B.LOND. (Essex).—It may be stated roughly that sugar is now one of the cheapest of fuel foods, a shilling spent on it yielding 11,000 calories, which is more than can be obtained from the same amount of money spent on bread. As a general rule, the consumption of sugar is in the inverse ratio of the consumption of alcohol.

F.R.C.S. (Lincs).—Our correspondent will find a recent paper in *La Presse Medical,* No. 70, in which Aubert puts forward strong arguments in favour of the conception of erythema nodosum as a "pre-tuberculous" manifestation. Other observers have also considered that this disease is frequently the expression of the earliest phase of infection with the tubercle bacillus.

Meetings of the Societies, Lectures, &c

WEDNESDAY, OCTOBER 29TH.

BRITISH OTO-LARYNGOLOGICAL SOCIETY (11 Chandos Street, Cavendish Square, W.).—4 p.m.: Clinical Meeting.

THURSDAY, OCTOBER 30TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF THE HISTORY OF MEDICINE) (1 Wimpole Street, W.).—5 p.m.: Professor G. Elliott Smith: The Contributions of Ancient Egypt to the History of Medicine.

ROYAL SOCIETY OF MEDICINE (SECTION OF NEUROLOGY) (1 Wimpole Street, W.).—8.30 p.m.: Presidential Address: Mr. William Thornburn.

CHILD STUDY SOCIETY, LONDON (Royal Sanitary Institute, 90 Buckingham Palace Road, S.W.).—7.30 p.m.: Prof. W. Rippmann: Child Speech.

MONDAY, NOVEMBER 3RD.

SOCIETY FOR THE STUDY OF INEBRIETY.—Fifth Norman Kerr Lecture by Sir Thomas S. Clouston, LL.D., M.D., in the Hall of the Royal College of Physicians, Queen Street, Edinburgh. 4 p.m. Subject: "The Clinical Aspects of the Study of Inebriety."

TUESDAY, NOVEMBER 4TH.

ROYAL SOCIETY OF MEDICINE (SUB-SECTION OF ORTHOPÆDICS) (1 Wimpole Street).—4.30 p.m.: First Meeting.

ROYAL SOCIETY OF MEDICINE (SECTION OF PATHOLOGY).—8.30 p.m.: Demonstrations at the Imperial Cancer Research Laboratory, Queen Square.

WEDNESDAY, NOVEMBER 5TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF OPHTHALMOLOGY) (1 Wimpole Street, W.).—8 p.m.: Cases by Messrs. Sydney Stephenson, George Coats, Charles Killick, A. S. Cobbledick. 8.30 p.m.: Papers by Mr. George Coats and Mr. C. Wray.

Appointments.

FRASER, Sir THOMAS, M.D.Edin., F.R.C.P.Edin., Chairman of the Medical Lecturers in the Royal Infirmary, Edinburgh.

GARRETT, P. C., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory and Workshop Acts for the Dursley District of the county of Gloucester.

LYLE, JAMES DUNCAN, M.B., B.S.Lond., M.R.C.S., L.R.C.P.Lond., Assistant Anæsthetist to the London Hospital.

MACKIE, WILLIAM, M.D., M.S.Aberd., Medical Referee under the Workmen's Compensation Act, 1906, for the Sheriffdom of Inverness, Elgin, and Nairn.

NELSON, H. RUNDLE, B.S., M.D.Dub., Quarantine Officer at William Head, Vancouver Island.

PALMER, S., M.D.Durh., Police Surgeon to the South District of Liverpool.

Vacancies.

Joint Counties Asylum, Carmarthen, South Wales.—Second Assistant Medical Officer. Salary £180 per annum, with board, lodging, washing, etc. Applications to the Medical Superintendent.

Kent County Asylum, Maidstone.—Fourth Assistant Medical Officer. Salary £200 per annum, with furnished quarters, attendance, coals, gas, garden produce, milk and washing. Applications to the Medical Superintendent, Asylum, Maidstone.

City of Westminster Union.—Assistant Medical Officer. Salary £160 per annum, with board, residence, and washing. Applications to W. J. Lickley, Clerk, Guardians' Offices, Princes Row, Buckingham Palace Road, S.W.

Lancashire County Asylum, Winwick, Warrington.—Assistant Medical Officer. Salary £200 per annum, with furnished apartments, attendance, and washing. Applications to the Medical Superintendent.

Bradford Union.—Assistant Resident Medical Officer.—Eastby Sanatorium. Salary £130 per annum, with rations, apartments, and laundry. Applications to George M. Crowther, Clerk to the Guardians, Union Offices, 22, Manor Row, Bradford.

London County Asylum, Hanwell, W.—Junior Assistant Medical Officer. Salary £200 per annum, with board, furnished apartments, and washing. Applications to H. F. Keene, Clerk of the Asylums Committee, Asylums Committee Office, 6 Waterloo Place, S.W.

Births.

CRAIG.—On October 24th, at 54 Welbeck Street, W., the wife of Dr. Maurice Craig, of a daughter.

MORISON.—On October 20th, at Marlborough Gardens, Stanwix, Carlisle, the wife of Dr. Morison, of a son.

MURRAY.—On October 25th, at 14 Moncrieffe Road, Sheffield, the wife of C. Graham Murray, M.D., of a daughter.

REES-ROBERTS.—On October 26th, at Danesfield, Walton-on-Thames, to Dr. and Mrs. Rees-Roberts, of 14 Park Lane, W.—a daughter (first-born).

TULK-HART.—On October 19th, at 4 Gloucester Place, Brighton, Blanche Madeline, wife of T. Tulk-Hart, M.D., B.S., of a son.

WILKINSON.—On October 26th, at Kemnal, Caversham, Oxon., the wife of Lt.-Colonel Edmund Wilkinson, Indian Medical Service, of a daughter.

Marriages.

BAILEY—SLOAN.—On October 22nd, at Sandyford Parish Church, Glasgow, the Rev. T. Graham Bailey, B.D., Church of Scotland Mission, Wazirabad, to Agnes Bankier Sloan, M.B., Ch.B., second daughter of Alexander Sloan, Chartered Accountant, Glasgow.

GILLIES—STEWART.—On October 22nd, at St. Giles, Edinburgh, Hugh Gillies, M.R.C.P., New Abbey, son of the late Dr. Hugh Gillies, Easdale, to Janet McCulloch, elder daughter of the late Captain William Stewart, of Shambellie, in the Stewartry of Kirkcudbright.

HOLFORD—LOTT.—On October 21st, at St. Mary Abbots, Kensington, Christopher Tredwell Holford, F.R.C.S.Edin., M.R.C.S.Eng., L.R.C.P.Lond., son of Mr. and Mrs. Christopher T. Holford, of 5 Northumberland Avenue, Putney, to Doris Emily Lott, younger daughter of Mr. and Mrs. Frank E. Lott, of Alexandra Road, Burton-on-Trent.

LACEY—BARBER.—On October 23rd, at St. Andrew's, Hertford, Herts, William Stocks Lacey, L.R.C.P.Lond., M.R.C.S.Eng., L.D.S.Eng., D.M.D.Harvard, only son of Mr. and Mrs. William J. M. Lacey, of Clyde House, Hertford, to Mabel, only daughter of Mr. and Mrs. Thomas Barber, of Castle Street, Hertford.

Deaths.

O'NEILL.—On October 15th, at Endsleigh Gardens, London, Surg.-Lt.-Col. John O'Neill, late of the Indian Army Medical Service, aged 65.

PARSONS.—On October 25th, at Fulham Infirmary, Hammersmith, W., Amy Elizabeth, the dearly loved wife of Christopher Thackray Parsons, M.D., and second daughter of the late James Hunter, Liverpool.

WILLIAMS.—On October 24th, at St. Thomas's Hospital, Doctor Edgar Williams, of Beyrout, Syria, aged 46.

NOTES AND COMMENTS.

Camberwell Again!

THE Metropolitan Borough of Camberwell seems to have a faculty for getting into the medical limelight. Her dispute, we understand, is still alive as to the propriety of storing trucks of town filth within a few yards of the Infirmary in neighbouring Southwark. The Camberwell Medical Officer of Health furnished a report explaining that the dust from the trucks could not traverse the intervening space. The good, easy minds of his Council readily grasped this theory as absolute proof that invisible germs of enteritis could not possibly have been conveyed from the trucks to the Infirmary. Nor did the Local Government Board see fit to intervene in this tempest of Bumbledom, behind the comedy of which were stretched the stark bodies of some dozen or so Southwark paupers. The attempt to get at the cause of their deaths has led to a pretty pother indeed! As the local Coroner has failed to deal with the deaths, it is somewhat interesting to find the Guardians of Southwark thus suddenly imbued with scientific curiosity. Last week the Camberwell Guardians were called upon to consider the strained relations between the Superintendent and the Resident of their own Infirmary. The Chief reported that the Assistant Medical Officers complained they had not sufficient time to play tennis, that they were restricted in piano-playing, and had to be indoors by 12.30 three times a week. It would, of course, be impossible to hazard an opinion as to the merits of the case without full information as to the conditions of the work performed by the Assistant Officers. All work and no play, as the world has long recognised, makes Jack a dull boy. Possibly the L.G.B. might be able to settle this point, which, be it said, in spite of its seeming triviality, goes deep into the root of all efficient medical service.

The York County Hospital.

THE affair of the York County Hospital is still unsettled, a fact that in itself furnishes a seathing comment on the chaos of our voluntary hospital system. Thanks to the initiative of the *Hospital*, a vigorous complaint by two former residents of the Institution in question was publicly and fully investigated. The inquiry was conducted by Sir Cooper Perry, who published a singularly able and just report upon the whole matter. In an internal dispute of the kind it is often extremely difficult to estimate the precise value of evidence and to arrive at demonstrably sound conclusions. In the present instance Sir Cooper had the assistance of a legal assessor, and learned counsel appeared on behalf of the various parties concerned. The result of the investigation may be thus summed up: Out of twenty-six charges made by the residents, fifteen were more or less successfully sustained. Some of the points thus established were of a serious nature, and revealed an administrative laxity and ineptitude of no ordinary degree. In short, the management of the York County Hospital was called upon to answer a scathing indictment before the bar of public opinion. Upwards of three months has elapsed since the publication of Sir Cooper Perry's report, a somewhat prolonged period, one would think, for the delivery of a formal reply by a management that has on more than one occasion indignantly repudiated the criticisms passed upon its methods of administrative control. To ordinary folk it seemed clear enough that the report had established beyond the shadow of a doubt the fact that reforms of a drastic nature were demanded if the York County Hospital were to regain its position as a well-ordered voluntary hospital.

The Committee's Explanation.

As the result of three months' deliberation, the House Committee of the York Hospital have furnished a report upon Sir Cooper Perry's report. It has held eleven meetings and has interviewed members of the medical staff as well as one former resident and the matron. As the result of its labours, it has furnished a white-washing document which has since been formally approved by the Committee and the Medical Board. The Sub-Committee, no less than the Committee itself, has apparently failed to grasp the elementary fact that it was responsible for the proper administration of the Hospital and that its admitted and established failure in various directions cannot be palliated by measures compounded of a few half-hearted confessions, of recriminations, of assertive denials, of evasions, and of self-congratulations and approval, combined with a modicum of suggested reform. The proper course, we submit, is to call together the governors of the York Hospital, and to ask them their candid opinion upon Sir Cooper Perry's report. At the meeting one would expect any self-respecting body of management, faced with an adverse public report of the weight and authority of the one in question, to hand in their resignations, which might or might not be accepted by the main body of the governors. The ultimate judgment must come from the public. Already, so it has been announced, the York Labour Party has resolved that it will advise working men to withdraw their support from the Hospital unless the recommendations of Sir Cooper's report are at once adopted. The management will gain nothing by deferring the date of their public defence. It is clear that the duties of a matron and her relations to the medical residents should be in future clearly defined in all hospitals that hope to escape "scandals" of the York County type.

The Anæsthetic Room. Most anæsthetists will agree that quiet and peaceful surroundings are desirable for the administration of ether and chloroform, especially to nervous and excitable patients. The dread of an approaching operation is a very real thing, and everything should be done to minimise the condition of mental distress, if not actual fright, that is apt to supervene prior to the ordeal. In the majority of modern hospitals the operating-theatre is provided with a room, or even a suite of rooms, in which the patient can be anæsthetised privately, so that he is spared the somewhat alarming vision of an array of instruments, bowls and trays. Where space has to be considered and no anæsthetic room is available it is usually possible to screen the various surgical paraphernalia from the patient's view. Even then, the knowledge that he is already inside the place of operation is quite sufficient to upset the nerves of a sensitive person, so that he is thereby less fit to take the anæsthetic quietly. In the case of a death under chloroform which occurred at a provincial hospital the other day, it was stated at the inquest that the patient was examined, anæsthetised and operated upon in the operating theatre. The heart failed, apparently, as the result of fright, for the organ was perfectly sound. The jury recommended, and rightly so, that patients should be examined and the anæsthetic administered before being taken into the operating theatre.

The Wisbech Demonstrations. Seldom have the death and funeral of a country medical practitioner been marked by such scenes as were witnessed last week at Wisbech upon the occasion of the interment of Dr. Horace Dimock, at Stretham. It will be remembered that the deceased was found dead in bed after proceedings for criminal libel had been instituted against him. Dr. Dimock was said to have been the last of the panel doctors appointed for Wisbech, and to have incurred a certain amount of local opposition, if not an actual boycott, thereby. However, he speedily earned considerable popularity, and he is said to have had 2,500 persons on his list. Local ill-feeling continued to run high, the sending of anonymous abusive postcards, alleged to have come from insured persons, to several practitioners in the district, resulting in the action referred to above. As the inquest upon Dr. Dimock has been adjourned we are precluded from speculating upon the cause of his death. It is significant, though, that one of the wreaths upon his coffin bore testimony to the fact that he was "worried by the few, but loved by the many." At any rate, it is easy to see from the expressions of sympathy passed at the huge mass meeting at Wisbech, attended by about 5,000 persons, that the deceased practitioner's services were appreciated by the public whom he served. It is satisfactory to note that the promoters of the meeting, together with the great majority of the more sober-minded among the crowd, dispersed quietly to their homes. A certain section of the mob, indignant at what they imagined was the unjust persecution of Dr. Dimock, smashed the windows of certain other medical practitioners who they thought were the cause of all the strife. The reading of the Riot Act and the arrival of a posse of police, happily relieved a situation the necessity for which need never have arisen if small misunderstandings had not been magnified.

LEADING ARTICLES.

THE COMMISSION ON VENEREAL DISEASE.

The recent appointment of a Royal Commission upon venereal diseases registers an event of first-rate social importance. Reduced to its simpler terms, it is in point of fact a logical development of that public health movement which has done so much to ameliorate the conditions of our modern civilisation. Once given the knowledge of the causation of various human infective maladies, and the application of measures of prevention must follow sooner or later in communities actuated by the elementary instinct of collective self-preservation. Modern medical science has enabled the State to legislate against infectious maladies by such salutary measures as vaccination, compulsory notification, isolation, and disinfection, and less directly by drainage, disposal of refuse, the supply of pure water and so on. The State, in fact, is realising the economic value of the health of the citizen as a national asset. In the matter of tuberculosis it has brought the full resources of the nation to bear upon its extinction, and it may be not unreasonably anticipated that ere long the world will be practically rid of that particular scourge. As to another widespread foe of humanity, venereal dieases, public sentiment has hitherto blocked the way to effectual collective action. The fact that such disease is commonly spread by impure sexual intercourse has led to a pretty general attempt on the part of society to ignore its existence. This attitude, however understandable to the moralist, is incompatible with the State-accepted responsibility of protecting the nation so far as may be from the ravages of infectious disease. The incidence of venereal maladies, like the rain from Heaven, is upon the righteous as well as the unrighteous. It would tax the subtlety of the sternest moralist to justify the transmission of syphilis or gonorrhœa to innocent persons by purely extra-genital channels. Medical science, however, has not to deal with motives or conduct in this particular matter, but is rather concerned with the expulsion of the malady from the community. Happily, such a consummation has been rendered possible by the rapid advances in pathology, diagnosis and treatment connected with such eminent observers as, to mention a few only, Schaudin, Wassermann, Ehrlich, Neisser, Noguchi, and, in our own country, MacDonagh. The present situation with regard to this class of disease is clear and encouraging. It is possible, in a word, to do away with syphilis and gonorrhœa as surely as plague, rabies and cholera have been banished from the shores of the United Kingdom. In response to an appeal by certain prominent members of the medical profession Government has appointed a Royal Commission of Inquiry into the circumstances attending the incidence and the prevention of venereal diseases.

There can be little doubt that, at some future time, the State will adopt measures of prevention based upon the information derived from the labours of their Commission. That intention will be strengthened by the encouraging results that have followed the application of modern scientific methods to the control of that class of disease in the army. A remarkable change of mental attitude has come upon society with regard to these special maladies. It is no longer thought shameful for pure-minded folk of either sex to have a knowledge of, and to discuss, their nature and their existence. Indeed, social reformers of the highest standing openly advocate that young persons, male and female, should not be brought up in ignorance of facts that may affect profoundly, not only their own future welfare. but also that of their children. It is not the first time that the legislature has considered the control of these diseases by statutory means. The Contagious Diseases Act was enforced for several years, and its operations were attended with no small measure of success. It was exceedingly restricted in its scope, however, and dealt with the public women only of certain towns. It was soon found that the women concerned were subjected to the risk of official injustice, and the Act was finally repealed at the instigation of a small but powerful band of opponents. There is no likelihood of a similar element of compulsion, directed against a single sex, being revived. It may possibly be one day possible to treat venereal maladies more closely on the analogy of the more serious ordinary communicable infections. That and other points of prevention will doubtless be threshed out before the Royal Commission, the appointment of which marks a new era in the evolution of a sane collective morality, based on the sure ground of science and guided by a firm grip of the economics of public health.

THE HEALTH OF THE CITY OF LONDON.

The Report of the Medical Officer of Health for the City of London always contains interesting matter, and that for 1912 is no exception to the rule. Dr. W. Collingridge, who has now relinquished office, was assisted in the preparation of the report by Dr. W. J. Howarth, the present Medical Officer of Health. On the subject of the milk supply, the report states that in order to determine to what extent milk on arrival in London could be regarded as responsible for the dissemination of tuberculosis a system of taking samples on arrival at the great railway termini within the City boundaries and submitting them to bacteriological examination was instituted in 1902. Thirty samples were taken in January last and submitted to Dr. Andrews for bacteriological examination. He reports: "I have on occasions, when the results of an investigation have been of a more satisfactory character, felt that the efforts made to secure a pure and wholesome milk supply for the people of London have not been altogether unsuccessful, but these feelings have been quickly banished by the unsatisfactory results of subsequent inquiries which have made it apparent that until the hands of farmers, dairymen, and others engaged in the distribution of this indispensable commodity are forced by Statute, no real or lasting improvement can be looked for. This investigation, however, revealed a marked improvement in the type of churn used for conveyance. The old objectionable pattern, which, under the mistaken idea of providing 'ventilation,' afforded means of access to all kinds of dirt in transit, is gradually being replaced by dust-proof, sealed and locked churns, which, if the milk be clean and properly cooled at the farm and properly dealt with in transit, will do much to ensure its delivery in a proper condition. Milk from which eighteen of the samples referred to above were taken was contained in properly constructed receptacles, locked and unventilated." Twenty per cent. of these samples were dirty, and 33.3 per cent. were clean. A matter of great practical importance is referred to by Dr. Collingridge, to which we alluded only a few weeks ago in our columns—namely, the question of the sanitation of offices where clerks, warehousemen, typists, and others are employed. Many such persons, who belong to a very deserving class, are "earning their daily bread in surroundings of a most unsatisfactory and even dangerous character." Here, again, common experience supplies conclusive evidence. In the business quarters of London there are thousands of offices which are as ill-suited and as ill-equipped as they could possibly be for the activities which they house. There are underground offices, offices with borrowed light only, offices in old buildings, ill-constructed, inconvenient, unventilated, and often undrained; offices so overcrowded that the atmosphere after a few hours is thick enough to cut with a knife. No doubt the high value of property has tended to bring about these results, but the question is whether they ought to be tolerated, having regard to the very large section of the population whose health is endangered. Parliament legislates freely for factories and workshops, for lodging-houses, for bakehouses, and for schools, why not for offices? The clerk and the typist have, after all, a great claim to consideration, and public opinion will be inclined to agree with Dr. Collingridge that it is a matter of regret that the Legislature does not furnish local authorities with more definite and efficient powers for remedying conditions in offices—conditions which in many cases must contribute largely to the spread of disease as well as to the depression of vital energy. We hear much of the need for housing reform nowadays; but the ends for which such reform is advocated can never be fully maintained as long as so many of the non-manual workers spend their working days in an environment that is thoroughly, and generally quite needlessly unhealthy. During the year under review 806 deaths were registered in the district, including 674 persons dying in the City but not belonging thereto. The deaths from phthisis correspond to a rate of 1.06 per 1,000 of the population, compared with 1.35 in the metropolis. The total death-rate for 1912 was 9.5 per 1,000 per annum of the population (the previous year being 10.9), whilst that for the whole of the metropolis was 13.6. Workers and residents alike in the City of London may have cause, therefore, to congratulate themselves upon the health of the great capital, which owes so much to the vigilance of its able Medical Officers of Health.

CURRENT TOPICS.

Speeding Up.

THE efficiency engineer has got a grip of the factories. He has drilled the operatives to eliminate so-called superfluous movements from their work and to employ only a purposive directness in the performance of the daily task. He was a great man, the joy of the capitalist and the workers' pride. Efficiency *in excelsis* was his motto, and a workman for him became, literally, a hand. Rectilinear ruthlessness was to oust the graceful curves of humanity in motion, regardless of the fact that it is physiologically imperative that muscles should not work by the shortest mathematical route. That is the difference between mankind and machinery. Only an untrained eye would deem the style and flourish we all associate with the efficient workman to be superfluous. It is during these graceful squanderings of time that the essential muscles observe a systole. If this infinitesimal liberty from labour is taken away fatigue develops fast and becomes permanent. The effect is decreased effectiveness. The speeding-up idea which has taken hold of our industries came from America, and even there it has lost its favour. The theory of the thing was wrong, and would have been obviously wrong to those who conceived it had they realised that a man is not a machine, but an animal.

Housing in Dublin.

DURING the past week the Lord Lieutenant and the Chief Secretary of Ireland received several important deputations to discuss the housing question, particularly as regards Dublin. The Women's National Health Association, the Dublin Citizens' Association, and the Housing and Town Planning Association, were among the bodies represented. One common demand was made by all the deputations that the Irish Government should appoint a Vice-Regal Commission to investigate and report on the whole matter. Public opinion in Ireland is unanimous on this point. Mr. Birrell, however, remains unconvinced. As we stated last week, he proposed in the first instance to appoint a Departmental Committee of the Local Government Board to make a private inquiry. He has been persuaded to modify this suggestion so far as the privacy of the inquiry is concerned, but he still regards a committee of the Local Government Board as a better instrument than a Vice-Regal Commission. His arguments in favour of this view are so weak that we feel compelled to think that he has not stated his real reasons. He refers to expense and delay. The expense of a Commission is not so formidable as Mr. Birrell suggests, and, considering the thousand and one purposes—more or less useless—for which Commissions are appointed, this objection does not carry much weight. To go no further: the importance of the subject is out of comparison greater than that referred to the Vice-Regal Commission on the Milk Supply which reported a few days ago. As to the delay occasioned by the appointment of a Commission, it would surely be better to proceed on a well-considered and complete scheme than to rush hastily into feverish activities. The reason for insisting on a public inquiry by independent men is easily stated. In stating it, we are not sure that we are not also stating the reason of Mr. Birrell's refusal. It is this. In so far as any public bodies can be held responsible for the deplorable condition of the health of Dublin, in which is included the housing of the working classes, two bodies must answer—the Dublin Corporation and the Local Government Board. They stand at the bar of public opinion, and they cannot at the same time occupy the bench.

The Predominant Prescription.

THE dead hand of the apothecary rests on us. He took something from a big box, and our patients still expect us to do the same. The lawyer gives advice, and even the rich he sends empty away; while the doctor is expected to part with drugs or their equivalent prescription. Our patient wants a portable instrument for obtaining a potable ingestion, and if he does not get it he is dissatisfied. The idea of a charm or amulet still survives to keep medicine a mystery. Every layman believes in the transferability of therapeusis to the extent of the omnipotence of "a good prescription." He does not yet see that the paper the doctor leaves behind him is not so important as the knowledge which he takes away. Facts and opinions in a case book are the valuable part of a professional visit, and as soon as this is really known the quack's day is over. Anyone can hand out remedies, but no one but a competent practitioner can extract the full knowledge of a case. The prescribing chemist could not use the information if he had it, and the real *mala fide* quack has no use for it whatever. What he wants to know is his victim's income.

Municipal Control of Lying in Institutions.

A RESOLUTION, unanimously adopted at a recent meeting of the London County Council, registers a public movement of no little importance. It pledged that body to apply next year for legislation conferring further powers in the control of all hospitals, other than poor-law institutions, and of premises used for lying-in purposes. It is asked that all such places be registered with right of entry of officers and of granting or of withdrawing licences. There is much to be said in favour of such a proposal, inasmuch as it protects the health of parturient women on the one hand, and strengthens the hands of the authorities, on the other hand, in dealing with a subtle and widespread branch of criminal activity. In spite of these obvious advantages, however, the legislation thus proposed deserves most careful attention, for it introduces the thin end of the wedge of State hospital service. If the principle be conceded in the case of the lying-in institutions, it can hardly be denied in the case of institutions devoted to other branches of medical practice. It by no means follows that if the London County Council had control of lying-in houses it would necessarily be able to keep them up to first-rate administrative pitch. A larger and more powerful body, to wit, the Local Government Board, although backed by the resources of the Government and governed by a man of exceptional strength of character, is by no means able to enforce high standards in Poor Law Infirmaries. Recently, the Board has shown itself impotent as dealing with so simple a case as an epidemic of enteritis in a Poor Law Infirmary said to be caused by a local filth deposit. The voluntary hospital system, whatever its faults, has of late years undergone a marvellous phase of evolution. It is open to question whether collective public enterprise can do better. It is to be hoped, at any rate, that the matter will be well threshed out before Parliament sets the seal to any hasty socialistic measures.

The Milk Supply of Ireland.

The Vice-Regal Commission on the Irish Milk Supply presented a unanimous report last week, which contains several recommendations of interest. As regards the alleged scarcity of milk there is apparently no scarcity in the larger towns, and only a slight seasonal scarcity in the smaller towns. In some rural districts there is a genuine scarcity sufficient to affect the health of the people, the scarcity being due in all probability to all the milk being sent to a creamery. The suggestion for the use of separated milk as a food is not likely to be welcomed. In regard to the purity of the public milk supply, the Commission recommends that the public health authority should have extended powers in regard to dairies suspected of conveying diphtheria or typhoid. It is suggested that the authority should be empowered to take the necessary steps to ascertain the presence of a "carrier" in the family or employment of the milk seller. Moreover, it should be possible to order the closure of a dairy on epidemiological evidence alone. We give a brief summary of the report elsewhere.

PERSONAL.

H.M. the King has been graciously pleased to approve the appointment of Surg.-Gen. A. T. Sloggett, C.B., C.M.G., K.H.S., to be Director-General Army Medical Service, in succession to Surgeon-General Sir Launcelotte Gubbins, K.C.B., M.V.O., M.B., K.H.S., when the latter vacates the appointment.

Dr. J. Murray Bligh has been appointed Lecturer in Clinical Medicine in the University of Liverpool.

Dr. F. G. Wrigley, M.D.Vict., has been appointed Honorary Assistant Surgeon to the Manchester Ear Hospital.

The annual dinner of the Huddersfield Medical Society took place the other day under the chairmanship of Dr. D. Lewis Cairns.

Mr. W. Bernard Secretan, M.B.Lond., F.R.C.S. Eng., has been appointed Assistant Surgeon to the Royal Berks Hospital, Reading.

Sir Arbuthnot Lane left London on Saturday last for the United States to give several addresses, and will return to London on December 7th.

Mr. E. Arthur Dorrell, F.R.C.S.Eng., has been appointed Assistant Ophthalmic Surgeon to the Prince of Wales's General Hospital, Tottenham, N.

Dr. Sanderson Long presided over the annual dinner of the York Medical Society last week, and the Orator for the year was Mr. Stephen Paget.

Dr. P. E. Walton-Smith, M.B.Syd., M.R.C.P. Lond., has been appointed Honorary Physician to the Royal Prince Alfred Hospital, Sydney, New South Wales.

We regret to learn, as we go to press, of the serious illness of Sir Donald MacAlister, Principal of Glasgow University. Our readers will join with us in wishing him a speedy recovery.

Dr. Arthur Rotherham, M.A., M.B., B.C., Medical Superintendent of the Darenth Asylum, has been appointed a Commissioner (paid) under the Mental Deficiency Act, 1913.

Dr. J. H. Yolland, County Director of the British Red Cross Society for the Bromley (Kent) Division, was the recipient of a suitable presentation the other day in recognition of his services.

Dr. C. A. Mercier will deliver the FitzPatrick Lectures at the Royal College of Physicians of London on Thursday, November 6th, and Tuesday, November 11th, on "Astrology in Medicine."

The annual dinner of the Bristol Medical School will take place on Tuesday, November 18th, 1913, at 7 for 7.30, under the Presidency of Dr. P. Watson-Williams. Sir Felix Semon, K.C.V.O., will be the guest of the evening.

Dr. F. W. Mott, F.R.S., will deliver an address on "The Degeneration of the Neuron in the Light of Recent Research," at the inaugural meeting of the Midland Medical Society, to be held at the Grand Hotel, Colmore Row, Birmingham, on Thursday evening, November 13th.

Dr. and Lady Philippa Stewart are to be presented by the Conservatives of East Grinstead with a piece of antique silver plate and an illuminated album containing the names of some 700 subscribers, as a silver wedding gift. Lord Colchester will make the presentation early in the present month.

Professor F. H. Edgeworth, B.A., M.D.Cantab., D.Sc.Lond., will deliver the eighth Long Fox Lecture in the University of Bristol on Tuesday, November 18th, at 4.30 p.m., on "The Cranial Nerves: Their Motor Nuclei and Muscle Sensory Fibres." Sir Isambard Owen, the Vice-Chancellor, will preside.

Sir William Collins, M.D., F.R.C.S., was entertained at dinner last week at the Café Royal by the house surgeons, registrars, and anæsthetists who have held office at the London Temperance Hospital during the 25 years that Sir William has been Visiting Surgeon to that institution, and a presentation was made to him by his former colleagues.

Sir George T. Beatson, M.D., K.C.B., was the recipient last week of a handsome presentation from the Superintendent and past Assistants and House Surgeons of the Western Infirmary, Glasgow, as an expression of their high appreciation of his services on the occasion of his retirement from the active staff, and his appointment to the honorary consulting staff of the institution.

Speaking at the annual dinner of the London School of Tropical Medicine on October 24th, presided over by Dr. F. M. Sandwith, Mr. Austen Chamberlain, M.P., said that the committee of which he was chairman set out to obtain £100,000 for the endowment and support of tropical medicine. They had not succeeded in this endeavour, but had obtained the not inconsiderable sum of over £70,000.

FRENCH CLINICAL LECTURE
ON
IS IT NECESSARY TO OPERATE IN SPINA BIFIDA?

By Dr. FROELICH,
Professeur Agrege in the Faculty of Medicine, Nancy

[Specially Reported for this Journal.]

Notwithstanding the great number of the publications inspired by spina bifida, surgeons are still far from a state of unanimity regarding the opportunity of intervention in cases of this congenital malformation of the spinal column, and the question of the most favourable time for operation. In order to arrive at a judgment in the matter of each of those questions, it is necessary to have at one's disposition observations that have been carried out during a great number of years, and to be able to examine without undue haste the respective series: on the one hand, of patients with exactly corresponding lesions who have been subjected to operation; and, on the other hand, of patients on whom no such procedure has been carried out.

The question has been discussed on the occasion of the recent communications to the Société de Chirurgie that were made by Rouville and by Delagéniere. MM. Kirmisson, Savariaud, Broca, Périer, and Walther took part in that discussion. But no well-defined conclusion has been arrived at as a result of those debates. In the following sentences, I purpose limiting my documentary evidence to the record of a certain number of personal observations made without interruption during fourteen years or so. I shall endeavour to extract from these the teachings which they convey. As all the observations that I am about to reproduce have already been published by myself or by my pupils, I may be permitted to sketch them very briefly.

Obs. 1.—In Froelich, *Etudes de Chirurgie interne*, Paris, 1905.—Male infant of eleven months, presenting lumbar spina bifida of size of fist; skin normal at base of tumour, but cicatricial and translucent over the summit, which is bilobar. No paralytic symptoms. The tumour is partially reducible. Operation, in 1898. Cure. Seen again in July, 1904, and presented at the Société de Médecine of Nancy. A perfect cure. Again in 1910, when the boy was 12 years old; on the left side the foot had developed equino-varus.

Obs. 2 (*Ibid.*, p. 81).—A young man, æt. 22. At the time of birth he was found to be affected with spina bifida, in the lumbar region; the tumour was soft, but irreducible, and of the size of a large nut. The contents were translucent. No treatment was adopted. Talipes equinus developed on the right side. When seen by us, at the age of 22, this deformity was very pronounced, with slight inclination to valgus; there was no trophic trouble. In the spinal region, there was a trilobar tumour at the level of the second lumbar vertebra, the base of which was surrounded by a collarette of long hairs. The consistence of the tumour was hard—fibro-lipomatous.

Obs. 3 (Thèse Martin, Nancy, 1912).—Boy, æt. 13. Affected from time of birth with spina bifida of the lumbo-sacral region; tumour of size of an egg; non-reducible; covered throughout with healthy skin. Movements of lower limbs normal. Extirpation of tumour at the age of six weeks. Healing by first intention. Histological examination revealed no neural tissues in the contents. The infant continued healthy till the age of 4. At that date, talipes equino-varus developed on both sides; and, soon after, incontinence of urine and fæces. At the age of 6, the clubbed feet were treated in the clinique of Dr. Kirmisson. At present date, the boy is 13 years old; the equino-varus is highly developed on both sides; there is also genu valgum. On the right ischium, a deep perforating ulcer. Incontinence of urine and fæces. Hypertrophic phimosis. The genu valgum was treated by apparatus; tarsectomy was performed for the clubbed feet. The phimosis was disposed of by excision. The lad is now able to walk with a cane.

Obs. 4 (*Revue Médicale de l'Est*, 1911).—A girl, æt. 10. Had been born with lumbar spina bifida, situated at the level of the second and third vertebræ; tumour of size of mandarine, and covered with healthy skin. No intervention was adopted. Seen in October, 1910. On the right side there exists a slight equino-varus, and a perforating ulcer beneath the metatarso-phalangeal articulation of the great toe. There was also slight incontinence of urine. The perforating ulcer healed after erasion, followed by three weeks' rest; the equino-varus was subjected to forcible reduction, after healing of the ulcer.

Obs. 5 (unpublished).—A lad, æt. 16, was sent us by Dr. Guyon, of Remiremont, on April 14th, 1908. At birth, a tumour of the size of half a chestnut was found at the base of the sacrum. No treatment was adopted. During the previous period of four years, the left foot had gradually developed equino-varus; there is limping gait, and incontinence of urine. On examination we found shortening of the left leg, by 3 c.c.; there is equino-varus; there had been on the same foot a sixth toe, which was removed when æt. 1. In the sacral region, there was a tumour of triangular outline—apex pointing downwards. The base was limited by a deep cutaneous furrow, and was garnished with a collarette of long hairs. The skin over the tumour was normal in appearance. The tumour itself was reducible. Between the skin and the reducible contents, a hard, fibrous *plaque* was interposed.

Such are our former observations of spina bifida. We shall now append our integrated statistics, in the endeavour to estimate the relative proportion of the operative mortality: that of operation and of non-intervention. Of fourteen children operated on by us, since 1898, during the early weeks following birth, five died a few days after the operation of broncho-pneumonia or of convulsions; four others succumbed in the course of the first year, two from the co-existing hydrocephalus, and two from progressive gangrene of the digits; the other five still survive, after the respective intervals of thirteen years and two years (*Obs.* 1 and 3); without hydrocephalus, but with motor troubles and incompetence of sphincters, slight or grave; of the remaining three, which have been operated on within the past two years, two are affected with hydrocephalus.

Of the seven children who had not been subjected to operation, three are still living (*Obs.* 2, 4 and 5) after respective intervals of 22, 11, and 16 years; two others are also still living, but are only 3 years old. One of these has progressive hydrocephalus; the other is in good condition, as regards cranial ossification and motility, but the tumour has not disappeared; two have died—one succumbed to digestive troubles, the other of rupture of the tumour preceded by convulsions. In the latter there had co-existed—in addition to hydrocephalus—complete paralysis of the lower limbs.

If we now regard but our twenty-one personal observations, we find that the operative mortality is 64 per cent.; while that of the subjects of expectant treatment was but about 29 per cent. It must, however, be noted that it was only the more favourable cases that were treated by the expectant method; the cases in which the tumour was inverted by resistant membranes, and had displayed no rapid increase of growth; while, on the other hand, operation had been adopted in the worst cases only—those in which the membranes were on the point of rupture, or had already become partially gangrenous, or even perforated. Nevertheless, the mortality remains a very high one, and the operative results are but little gratifying; and such is the experience of all surgeons who have had long experience of the surgery of infancy (Kirmisson, Broca).

The ultimate prognosis depends, as we have already said, on the contents of the tumour. That is evident. But it is not necessary that one should allow himself to be influenced too far, and give a prognosis too favourable in consequence of a negative histological examination. In our *Observations* 1 and 3, the tumours seemed to be pure meningoceles, as the tissues excised with the tumour were of fibrous structure. Nevertheless, in *Obs.* 1, medullary phenomena supervened after a period of ten years, in form of an equinovarus; and in *Obs.* 3, after four years, corresponding deformities of the feet supervened, with incontinence of urine and fæces superadded.

The explanation of those tardy spinal changes may be sought, perhaps, in adhesion of the meninges and nerve filaments to the rachidian orifice. When the patient grows up, as there is no correlation between the elongation of the spinal canal and that of the spinal cord, the latter becomes dragged-on; and paralysis of the lower limbs, and trophic disturbances, begin to appear. Nor should we forget that Lannelongue had already advanced the view, in the thesis of Dubreuil (Paris, 1902), that the formation of the tumour in spina bifida is but a secondary fact; defective evolution of the spinal cord being the primary one. The same observation harmonises with certain of the phenomena of spina bifida occulta. Furthermore, we have met with three children for whose cases we were consulted between the tenth and thirteenth year; for deviations of the feet which had developed tardily and progressively. Talipes varus existed in each of the three cases. In two of them there were slight trophic troubles in the plane of the ball of the great toe and of the calf; where red patches appeared and some points of ulceration developed. On examination of the vertebral column, we did not, at first, notice any modification of the integument; but on palpation, there was discovered, at the lower extremity of the lumbar column, an opening of the rachidian arches, which permitted the introduction of the finger; and of which the compression caused pronounced pain. Absence of the posterior arch of the fifth lumbar vertebra was easily verified by radiography.

In those three cases (spina bifida occulta of very slight development) there was no tumour, no hypertrichosis; merely a hiatus in one of the posterior arches of the spinal column. Nevertheless there was supervention of paralytic and trophic troubles. Is the cause, as in the cases of true spina bifida, a primary malformation of the spinal medulla, with retarded manifestations?—or, are these due to adhesions, consequent on the vertebral dehiscence of the osseous structures, between the bones and the membranes of the cord, and the consequent dragging of the latter at the period of increased growth?—or is it that the solution of vertebral continuity exposes the neural structures to ready traumatisms? All those hypotheses are respectively possible. With such restrictions, it is certain that the best operative results are to be anticipated in presence of a meningocele or myelocystocele; tumours in which the integuments are often undamaged, and the portions of the nervous system therein contained are of relatively little importance and easily reducible within the spinal canal after extirpation of the fluid capsule. But, on the other hand, in cases of myelo-meningocele, with its characteristic aspect of a tricolour cockade, enclosing nearly all the nerve structures destined for the supply of the lower limbs, operative procedure carries with it the risk of a deplorable result. Nevertheless, in two of the cases of children which were presented in conditions sufficiently unfavourable, the complete extirpation of the sac did not in any way diminish the motility of the limbs during the whole period of survival. This fact would indicate that a sufficient supply of nerve structures had remained within the canal to guarantee the innervation of the lower limbs. Such innocuity of the main nerve trunks in cases of spina bifida has already been indicated by Denucé and Piéchaud, in their "Précis de Chirurgie Infantile."

The anatomical investigation of spina bifida has been carried out in the most perfect manner by Professor Muscatillo (of Catania), and by Professor Denucé (of Bordeaux). And, most recent of all, the "Traité de Chirurgie," of Le Dentu and Delbet has displayed with much discrimination the anatomy and surgery of hydrorachis. Our personal observations go to prove that spina bifida is a grave lesion, whatever may be the anatomical aspect in which it presents itself—meningocele, myelocystocele, or myelomeningocele—from the fact of the great mortality which it occasions, whether the affected children undergo operation or not. Among the children who survive—whether the course adopted be that of operation or expectation—a great number, if not all, will gradually present, after the lapse of ten or twelve years, motor troubles in the lower limbs, paralyses of the sphincters and trophic ulcerations (talipes equino-varus, perforating ulcer). And the children who have not been subjected to operation appear to present those tardy developments in degree not less intense than those who have been.

Our conclusion accordingly is that: operation should not be carried out, whatever may be the anatomical formation of the spina bifida, except in those cases in which operative procedure is necessitated by a rapid increase in growth of the tumour, by imminent rupture, or by the appearance of patches of ulceration on the surface. In all other cases, we should await developments, while protecting the tumour with an appropriate apparatus.

In an article which recently appeared in the *Archives de Chirurgie* (October 25th, 1912), inspired by Professor Jeannel of Toulouse, and written by MM. Tournier and Ducuing, the subject of dealing with spina bifida of old standing is discussed; and conceptions are displayed which correspond, for the most part, to those which we have just indicated. The authors affirm, however, that "every case of old-standing spina bifida should be operated on, when displaying recent complications." I feel myself unable to subscribe to this precept; and, indeed, the two observations which are offered in support of the view are by no means convincing. Operation, at most, can have but the effect of aggravating the motor lesions and those of the sphincters. And, with regard to scars and perforating ulcers: these are readily and rapidly curable by the methods of local treatment, aided by rest and appropriate dressings, as we have frequently had the opportunity of proving.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Sir Arbuthnot Lane, Bart., M.S.Lond., F.R.C.S. Subject: "Chronic Intestinal Stasis."*

ORIGINAL PAPERS.

POST-OPERATIVE INTESTINAL STASIS AND THE INTRA-ABDOMINAL USE OF OIL (a)

By WATERS F. BURROWS, M.D.,
New York.

SINCE my subject has reference to a post-operative abnormality, it is interesting to note that much has been accomplished in hastening convalescence and eliminating the discomforts and complications of the surgical patient by permitting early post-operative freedom of movement and through placing of the patient in the partial or complete sitting posture after the administration of a general anæsthetic. The abdominal case operated upon without delay, returned to a bed raised 18 to 24 inches at the head, permitted to move from side to side and sit upright in bed upon the second or third day, convalesces rapidly and, more important, avoids such complications as embolism, thrombosis, pneumonia, and difficult micturition, with its dangers of cystitis, when catheterisation is required. Intestinal functioning is likewise bettered, there is less inhibition of peristalsis, and evacuations occur sooner; yet frequently intestinal disturbance is shown by a coated tongue, loss of appetite, abdominal distension and pain, while excessive vomiting and inability to easily pass gas or bowel contents by rectum emphasises the fact that there are other important considerations.

Referring, in this communication, not to the cases with more or less complete inhibition of intestinal peristaltic activity, such as is present in advanced peritonitis, nor to those where there exists an obstruction, dependent upon adhesions, kinks, exudates, rupture of the operative wound, or accidental constrictions of the gut caused at operation, but to the more common ones, with less interference with the fæcal current, seen after many abdominal surgical procedures, it is evident that the last are associated with a regional or segmental gut spasm. There is present a form of intestinal obstruction, accompanied by its usual signs, vomiting, some abdominal distension and inability to readily pass bowel matter and gas. The bile-stained, continued and often excessive vomiting is not fully accounted for by the gastritis resulting from the anæsthetic. The comparative rarity of true fæcal vomiting indicates the evanescence of the obstruction, which seldom exists long enough or to the extent necessary to cause regurgitation from the ileal loops. Fæcal vomiting, however, does occur in this condition, may be mistaken for acute gastric dilatation, and overcome without the necessity of secondary operation, required when some mechanical ætiological factor is present. Acute abdominal pain develops, dependent upon intestinal spasm and œdema, while proximal to the gut involved increased peristalsis occurs. Accumulation of gas follows when obstruction is unrelieved or spreading peritonitis is present, and meteorism may become extreme, indicating over-distension and relaxation of the intestinal musculature, and a congested, sluggish circulation, conditions favourable to the spread of intra-abdominal inflammation. Pain then becomes much decreased on account of the septic condition which supervenes and from discontinuance of muscular spasm. In its place there is the distress which results from encroachment of abdominal viscera and diaphragm upon the thoracic cavity, breathing becomes more difficult, and interference with heart action increases its irregularity and adds to the abdominal vascular disturbance. Associated with the condition there is always more or less irregular peristalsis, distension, and incomplete evacuation of the colon and rectum, which to some extent explains the beneficial results of an effectual stimulating enema. However, the expulsion of gas, following a rectal irrigation is not in itself as important as the reflex, activating effects which a successful colonic stimulation exerts upon the rest of the intestinal tract, causing a return to normal, uninterrupted, wave-like peristaltic contractions.

The small intestine is usually the site of the abnormality, as is shown by the diffuse character of the pain and distension, when present, which are not typically colonic. With distension of the colon pain is never so severe, or only becomes so when, with obstruction, the small bowel distends secondarily; it is more definitely located, either in the sigmoid, most frequently, cæcum or other portion, and the "ballooning" is most marked in the transverse colon, above the level of the umbilicus. Moreover, that the small bowel, not the large, is involved, is clinically demonstrated by the frequency of serious excessive vomiting and severe abdominal pain following operative procedures upon the small intestines or in the upper abdomen, where they are more exposed to irritation during operation than in either pelvic or iliac regions. In the lower animals, the dog in particular, the small gut contracts violently and becomes a stiffened spastic tube upon even moderate irritation, whereas the rectum and large bowel are less perceptibly affected.

(a) Paper read in the Section of Surgery, before the International Congress of Medicine, London, August, 1913.

During the early stage of post-operative intestinal stasis the prognosis for spontaneous return of normal peristalsis is good, relief is affordable, and suitable measures favour the propulsion and evacuation of intestinal contents, but with the advent of distension, following a primary period of spasm and pain, the condition present has, almost without exception, passed what might be termed an exaggerated physiological stage, has become pathological and demands secondary operation. In the aged, following operations where large intra-abdominal growths have been removed, and where a relaxed belly wall exists, there may occur, in the absence of actual obstruction, a degree of distension post-operatively which is not usual. In these instances there is the distress caused by pressure upon the respiratory and circulatory organs in the thorax, but absence of severe abdominal pain. The condition is one of intestinal atony, associated with deficient intra-abdominal pressure; the danger is less, and with stimulation, especially the use of strychnine, atropine, enemata, and extra-abdominal pressure, intestinal activity is regained.

The Treatment of Intestinal Stasis and Spasm consists in resorting to rectal enemata, containing soap, turpentine, alum, castor oil, glycerine, magnesium sulphate, etc., in combination or singly, or the use of large, continuous, saline rectal irrigations, with or without essence of peppermint, added. Strychnine aids the weakened patient; atropine, in large doses, inhibits abnormal spasticity; turpentine stupes and mustard paste, applied to the abdomen reflexly, favour return of normal peristalsis; and the rectal tube left in place for the escape of gas, and stomach lavage, may both be effectual. Eserine, theoretically contra-indicated, is often used to overcome an intestinal atony, erroneously believed present, while "hormonal," acting similarly and more powerfully upon a bowel already in spasm, is consequently additionally distressing and ineffectual in producing results in the worst cases. Attempts through enterotomy to empty the gut of its contents, with failure to eliminate the cause of obstruction, is attended with almost universal disaster. The position of the patient, lying upon the side, especially the right, is often a means of affording relief, and the partial sitting posture, drinking of fluids, and early taking of solid food conserve energy and hasten recovery. Morphine is indicated in many instances, not only controlling pain, but, through relaxing the spastic gut, aids intestinal propulsion.

The pain, disturbance, and actual dangers resulting from post-operative bowel stasis make evident the importance of prophylaxis. Not only are the means used to remedy the condition largely symptomatic and only partially effective, but some of them are in themselves attended with discomfort, and often repeated procedures, each adding to the patient's fatigue, are required before a normal condition is restored. All attempts at prophylaxis depend upon recognition of the causes of post-operative stasis, and these may be classified as follows:—

1. Irritation of the intestinal musculature or peritoneum, resulting in spasm and obstruction at the site of excitation, with consequent increased peristalsis and accumulation of intestinal contents proximally, and in a reflex contraction at other susceptible portions of the alimentary canal.

2. A secondary circulatory engorgement, which prevents the absorption of the gas and renders peritoneal and other tissues less resistant to spreading infection.

3. The restoration of intestines to non-anatomical positions and the oversight, at operation, of kinking or prolapse.

4. Abrasions of the visceral peritoneum, followed by adhesions sufficient to cause angulation or to retain a displaced bowel in abnormal position.

To avoid intestinal irritation at operation, it is important to have large or easily enlarged incisions, to minimise the use of foreign substances, such as sponges and pads, within the abdominal cavity, relying instead upon posture of the patient, to manipulate the gut, when required, with a gloved hand, to avoid infection and exposure of intra-abdominal parts to the drying effects of air or to all but body temperatures, failing which congestion follows (consequently as little evisceration as is feasible), to eliminate from the operating-room all irritating solutions in bulk, such as plain water, bichloride of mercury solution and alcohol, which upon the hands might gain entrance to the belly, and to exclude the use of all chemicals, such as phenol or iodine, employing instead the actual cautery, the effects of which are controllable.

Evisceration and faulty replacement of intestinal coils or displacement and angulation, following operative procedures, are frequent sources of unrecognisable mild intestinal obstruction. Concerning the position of small intestines, Mall says, "The jejunum first arranged itself into two distinct groups of loops situated well up in the left hypochondriac region. Each group made more than a complete circle and both of them came in contact with the anterior abdominal wall. After this the intestine passes through the umbilical region to the right side of the body. Then the intestine recrosses the median line to make a few convolutions in the left iliac fossa, after which it fills the pelvis and lower abdominal cavities between the psoas muscles." To a great extent misplaced intestines and purely mechanical disturbances will be restored, after operation, to normal position and overcome by physiological shifting, of which the gut is capable. However, with any abdominal distension or in the presence of fresh adhesions this is made more difficult or impossible. Likewise an omentum, placed in malposition or spread out and pulled down into the lower abdomen, always tends to regain its natural position, carrying with it and kinking coils of intestine to which it may have adhered, or, becoming involved in the inflammatory process, it may press upon or constrict the intestinal lumen. Mechanical obstruction may have origin, moreover, in a mobile, prolapsed cæcum, ileal kink (Lane) ptotic colon, or voluminous sigmoid, all of which portions of gut should be inspected, when practicable, during operation.

The Value of Mineral Oil in Intestinal Stasis.

Abrasion of the peritoneal surface of the gut is a most common and, frequently, unavoidable cause of post-operative intestinal stasis. The method of overcoming the effects of this traumatism by means of mineral oil, introduced within the abdominal cavity at operation, has proved effectual and safe. Wilkie concluded that sterile vaseline oil could be used intra-abdominally in suitable cases without danger, that it was of value in mopping over denuded surfaces in operations for peritoneal adhesions; Crump used similarly an oily animal extract, and others, including Blake, Seuffert, Hirschel, Krecke, and Kolb, resorted to plain or camphorated oil to combat peritonitis. The advantages of using neutral oil intra-abdominally was more fully demonstrated, however, in the following case, where a larger amount of mineral oil was used than had ever before been resorted to or thought desirable, so far as a research of the literature upon the subject indicates.

A patient, a woman æt. 32, was operated upon early in January, 1913, for the relief of obstinate constipation and cæcal distress; volvulus of the cæcum was found and appendectomy and cæcopexy performed. The patient left the hospital upon the seventh day, and for a few days the bowel evacuations were natural, but a certain amount of "gas" pain and attacks simulating increased peristalsis now occurred. The pain became severe at the pyloric region and was associated with vomiting which gave temporary relief. Upon each of the twelfth, thirteenth, and fourteenth days vomiting occurred three or four times, and pain, coming at intervals, was controlled by lavage. Upon the fifteenth day vomiting became more frequent, occurring every two or three hours, colicky pains became severe, and enemata resulted in the passage of a little gas and particles of fæces. The temperature, which had been normal, rose to $100\frac{1}{2}^\circ$ at 4 p.m., the pulse remained under 90, but considerable general abdominal distension appeared. Two hours later, at secondary operation, coils of small intestine, beginning at a point about one foot from the ileo-cæcal valve, lying to the left of the mesentery and filling the pelvis, were found matted together with extensive, fresh, soft adhesions, sufficiently firm to cause acute angulation in three places, and constriction in others. Upon separating them, which was done by blunt dissection, areas of peritoneum were torn off, and denuded portions of gut, aggregating approximately 10 square inches, remained It was found necessary to break down adhesions at about twelve places, involving perhaps 8 ft. of bowel. The site of absolute obstruction was near the cæcum, the intestine distal was collapsed, that proximal greatly distended, but as usual it was the jejunum which suffered most in this respect. This part of the gut for 3 ft. was distended to double its normal, black, but still presenting a glistening peritoneal surface. The peritoneum ruptured in several places upon putting back the jejunum, evisceration having been required, its walls were so thinned out and tense that sutures would not hold, and attempts in this direction were soon abandoned. Six ounces of liquid petrolatum or mineral oil were sterilised, poured into the abdominal cavity and spunged over the coils of intestine. Approximately five ounces of oil were left within the abdomen, the fluid welling up into the wound upon closing the belly wall. Convalescence was uneventful except for the occurrence of an extensive urticaria and temperature of 102° upon the fifth day, the temperature remaining at other times under 101° F. The pulse-rate, after leaving the table, was 128, but soon dropped to below 100; no vomiting followed operation, nor did "gas" pains, other than low colonic ones, relieved at once by rectal irrigation, reappear; but as a precaution cathartics were given early and persisted with for three weeks. The patient again left the hospital before the completion of a full seven days.

The writer has carried out a series of animal experiments showing the harmlessness and value of neutral mineral oil, used intra-abdominally. In most simple abdominal operations its use is not required, since prophylactic care will limit post-operative distress, but in all others the oil is of the greatest value when employed upon abdominal pads, during operation, or sponged gently upon intestinal coils, previous to closure of the incision, excluding only areas where adhesions are desired, and having care that all plastic procedures and intestinal anastomoses are completed before oil is introduced. In cases presenting extensive adhesions, or widespread peritonitis, large amounts of oil (up to 6 or 8 ounces) are required to prevent recurrence or formation of adhesions, to limit the absorption of toxines from the peritoneal cavity, to assist nature in combating the infection, and as a prophylaxis against intestinal stagnation, obstruction, spasm, and final paresis. In the case of more than moderate severity, intestinal spasm and stasis, together with abdominal pain, are largely eliminated and convalescence is made more comfortable and safe, while the individual in dire straits, at the time of surgical interference, has, post-operatively, manifoldly better chances of recovery.

Conclusions, based upon the peritoneal reaction to chemical irritation and upon the results of using neutral oil intra-abdominally to control infection and effects of traumatism, both mechanical and chemical, as observed in guinea-pigs and dogs (a) are as follows:

1. Iodine, mercuric chloride solution, carbolic acid, alcohol, etc., applied to the peritoneum, rapidly spread beyond the area intended, through capillary action and affinity for the tissues, destroy the endothelial cells, cause an excessive exudate, and tend to produce permanent adhesions.

2. Olive oil, containing fatty acids, and commercial liquid petrolatum, the impurities of which are acids, resins, fats, and oils, both animal and vegetable, combining irritating substances with a bland oil, produce inflammation of intact peritoneal surfaces, as is shown by the occurrence of a watery hemorrhagic exudate, which differs, however, from that which takes place in the absence of oil, in that agglutination and organisation do not follow.

3. Bland, non-irritating oil, represented by purified liquid petrolatum obtained from Russian oil, causes none of the changes occurring in the process of adhesion formation, which are endothelial cell injury, coagulable exudate, agglutination, organisation, and finally connective tissue and fibrous scar prodution. The oil has no appreciable chemical action upon the tissues, nor deleterious effect upon the animal, and is slowly absorbed.

4. Oil, used intra-abdominally in sufficient quantity, prevents, to a great extent, the formation or recurrence of adhesions.

5. Oil fills the lymphatic channels leading from spaces denuded of peritoneum or opened by incision, thus limiting septic absorption, and, through preserving the endothelial cells, prevents extension of destructive processes.

In his lecture before the Royal Society of Medicine last week, Professor Elliott Smith stated that during his experience in Egypt he had examined 20,000 bodies. Some of the prehistoric bodies dating back 60 centuries were in a marvellous state of preservation, and even bloodstains could still be seen. He had discovered splints which went back to the time of the Pyramids. In the earliest cemetery ever excavated in Egypt they found that all the men had been circumcised.

SOME OF THE PSYCHOLOGICAL AND CLINICAL ASPECTS OF ALCOHOL. (*a*)

By SIR THOMAS CLOUSTON, M.D., LL.D.,

Author of "Clinical Lectures on Mental Diseases," "The Hygiene of the Mind," "Unsoundness of Mind," etc.

In tackling the psychology of alcohol, one of the first questions that occur to the medico-psychologist is a historical one—What has been the effect of alcohol on the brains, mind, and conduct of the men who in their lives have exhibited the supreme qualities of human nature? Though this particular point has not come out in all the biographies of such men, profuse as have been the details related in their Lives, yet we know enough to form reasonably correct conclusions in the case of some of them. Taking Alexander the Great, Socrates, Moses, Solon, Julius Cæsar, St. Paul, Mahomet, Francis Bacon, Shakespeare, Goethe, Napoleon Bonaparte, and Darwin—those men being of different races, living in different ages of the world, all strongly influencing its history, and certainly representing the best that evolution has been able to do for men. Alcohol was known to all of them, and was in common use in their time. None of them except Mahomet abstained from its use, and none but he laid down any definite rules against it. St. Paul included drunkenness among his seventeen deadly "works of the flesh" which debarred men from the Kingdom of Heaven, but he enjoined its medical use to Timothy. Even Jesus Christ converted water into wine in order to add to the happiness of a small company of Jews, in accordance with a social custom of the time. He seems to have used wine in His daily life, for He said at the Last Supper: "I will not drink *henceforth* of the fruit of the vine." We cannot say that much guidance can be obtained from any of these in regard to the moderate use of alcohol. Solomon certainly spoke with two voices in regard to it.

The difference in the effects of alcohol on the two sexes is very great. Less alcohol will show bad effects on the brain of the average woman far sooner than in that of the average man. The woman seems not to have so commonly the kind of craving that men have for either alcohol or tobacco; but when they do come under the influence of the stronger liquors, a craving is set up which is more uncontrollable and difficult to deal with than it is in the average man. When many women take to the stronger drinks, it has a far more generally demoralising and disastrous effect on the whole social organism. In this respect the woman's brain in civilised countries is like the brain of the primitive peoples.

When we analyse the psychological effects of alcohol, we find that the first effect in the average human being—to which, however, there are many individual exceptions—is to accentuate the feeling of organic satisfaction. It produces happiness of a certain lower and bodily kind, analogous to that of a full meal It also accentuates the common social pleasures of intercourse with one's kind. It increases the gregarious tendencies of man. It tends to dull feelings of responsibility, of worry, of insistent duty, and of a serious view of life. It diminishes the tendency to take trouble about things. Looking to the pure emotions and higher pleasures of love, idealism, filial and parental affection, it undoubtedly tends to put those on a lower plane, diminishing their ideals.

Looking to the reasoning power—I am still speaking of the effects of a moderate amount of alcohol circulating in the brain—it cannot be said in any way to increase a man's power of coming to right conclusions from facts or to strengthen any form of reasoning whatever. It does, to begin with, seem to increase the power of endurance of irritations and hardships, and to diminish the sense of intellectual fatigue; but I believe that this is transitory, and does not last long enough to pay for its being so employed for such purposes.

Taking the virtue of courage, which is partly a mental and partly a bodily quality, alcohol may undoubtedly increase it; but it does so by diminishing the rational fear of consequences and lessening those protective instincts of which fear and even cowardice are expressions. It produces a sort of "Dutch courage." Undoubtedly it has been the custom in many nations to give alcohol to their soldiers on the eve of a battle, and probably that produces a greater willingness to a rash exposure of their lives.

Analysing next the effect of alcohol on the great human quality of imagination, does the stimulation of the brain by alcohol increase this wondrous faculty, or does it not? is a question of the profoundest importance to all civilised peoples. Human opinion has been divided on the subject from the earliest times. Many of the very great artists and the creators of literature and song have maintained its real stimulating power.

There is one great gift which only great men have possessed, and not all of them—that is, the gift of oratory—needing a large power of speech, a perfect choice of words, a high imagination, an influence for the persuasion of others, and intense feeling, all combined. Fox and Pitt undoubtedly depended, probably far too much, for the transitory power to make great speeches, on wine. John Bright, the greatest political orator of modern times, did not do so. Gladstone did not do so. Other modern orators are much belied if they did not resort partly to the stimulus of wine when they were to deliver a great speech. It may very well be that alcohol may stimulate a great orator for a great effort, but it is certain that constant resort to such a stimulus is an extremely dangerous thing both to his oratory and to his future length of life; but in this, as in everything else with which alcohol has action, much depends on the innate and hereditary qualities of the brain.

The faculty of memory cannot be said to be in any way stimulated by alcohol; on the contrary, it tends always to be obscured and made less accurate.

The power of attention is a faculty which many psychologists have carefully studied of late years. It relates to the action of the special senses, and the manner in which the impressions from them become a part of the mental furniture. Without attention there would be little memory, and therefore an insufficient basis on which to form sound reasoning judgments. I think it may be stated without hesitation that the action of alcohol on the power of attention is to make it less keen.

Rising to the supremest mental faculty of all—that of the will—can it be said that alcohol has any effect in strengthening it? The ego, the self, the conscious power of choice, free will, the power to do this or not to do it, the faculty of inhibition, is certainly not rationally strengthened, and may as certainly be greatly weakened by the presence of alcohol in the brain, through which will-power is exercised. At least, this is so under the ordinary circumstances of life. When a great choice has to be made by a man, when a great temptation has to be resisted, when the wills of other men have to be dominated by great volitional and mental efforts, who would advise any man to take to alcohol to help him to exercise this supreme power? If he needs such help, his brain is to that extent shown to be weak.

Taking the faculty of speech, which implies both bodily and mental effort, how is that usually affected by alcoholic stimulation of the brain? In nine cases out of ten it is stimulated. The company at a dinner party nearly always begins to talk more after the first glass of champagne. The speech centres seem to act more freely; the ideas find a readier outlet. Excess of alcohol notoriously affects, not only the mental part of speech, but its muscular apparatus. In some persons speech is affected at once by a very small quantity. It is rare that alcohol produces silence. Men are rasher and less cautious in action under its influence. They will thoughtlessly run more risks to their lives when under its influence. Forty per cent. of the suicides in England are due to alcohol. The great instinct of sex and reproduction does not seem to be, in itself, stimulated by alcohol: but, undoubtedly, less pains are taken to restrain that instinct within moral and conventional limits, and

---

(*a*) Abstract of the fifth Norman Kerr Memorial Lecture, delivered in the Hall of the Royal College of Physicians, Queen Street, Edinburgh, on Monday, November 3rd., 1913.

things relating to it are talked of far more freely than when men and women are not under its influence.

Desire is one of the fundamental qualities of man and every one of the higher animals. It is a normal, necessary and primary attribute Desire in an accentuated form becomes a craving, and that craving may be under control or pass out of the regulation of the will. Now, alcohol has in many human beings the fatal power and tendency to rouse an ordinary desire into such a diseased craving. This is one of the most injurious and common of all its evil results on certain human brains. If there is in addition to this an impaired power of inhibition, an actual disease is thereby constituted. The craving becomes uncontrollable. This occurs in the condition we call "dipsomania."

Many of the conventionalities of social life are very essential to civilisation. They contitute a minor code of morals. They are the practical aspect of Lord Haldane's *sittlichkeit.* They express the proprieties, the gentlenesses, and the pleasant things of our lives. In many ways they distinguish civilisation from barbarism. It is certain that any excess of alcohol tends towards a setting aside of many of those conventionalities. A gentleman is presumably under the influence of liquor or slightly off his head who walks along Princes Street without his coat, or even fails to raise his hat to a lady friend, for instance.

The habitual use of alcohol in any degree over the strictest moderation, in my opinion and experience, certainly tends to bring on the signs of old age before their time. Grey hairs, disinclination to muscular exercise and mental exertion, blurred facial expression, loss of keenness of eye, loss of memory, diminution of the usual interest of life, selfishness, are all more apt to come before their time in the man given to take a "little too much."

Some of the Clinical Aspects of Alcohol.

The chief clinical symptoms of alcohol in almost every form have been already described by many authors in many languages. The first treatise of any importance on this subject was written in Norway before the middle of last century. At that time the manufacture and sale of strong alcoholic drinks was absolutely uncontrolled in Norway, and in consequence alcoholism in exceedingly bad form was rampant among the population. This fact and its sequel—which was that the Norwegian Government had, for the sake of the health of its population, to pass stringent laws affecting both the manufacture and the sale of strong alcoholic drinks—had the result that the consumption of it was enormously diminished, and that alcoholism became a rare disease instead of the most common to be met with in Norway. That is a very notable contribution to my subject, and is a most important fact in studying the psychology of alcohol as well as its medical aspects. In what I have to say on the clinical aspect of the subject I shall largely confine myself to its mental and nervous symptoms and to my own personal experience in this department of the subject. I find. as I have said, that I have had under my care, in the fifty years of my practice of medicine, over two thousand cases of alcoholism with mental symptoms, 60 per cent. of those being men and 40 per cent. women. The proportion of alcoholics in the total number of mental patients under my care during that time was 14.5 per cent. Alcohol is, in fact, the most frequent cause of insanity, no single cause approaching it in numbers except the predisposing one of heredity to mental and nervous diseases. In those cases there was seen almost every variety of alcoholic damage to brain and mind. The clinical psychology of a definite toxin like alcohol is of special interest to the mental doctor on account of this definiteness in ætiology. To anyone not acquainted with the human brain and its physiological and pathological conditions, it might be rashly assumed that, the cause being so definite, the clinical effects would also be the same in almost every case. This was very far indeed from being so. Nothing could illustrate better the extraordinary differences between one brain and another than the variety of pathological effects on mind and body which alcohol is capable of producing, either when taken in single doses or for long periods. Those ranged from slight mental elevation up to complete destruction of mind, and from slight insomnia up to complete motor paralysis.

The actual number of patients which passed under my care where alcohol in some way had to do with the mental symptoms was much larger than the number where the symptoms were characteristically those of alcoholism. I did not include under "alcoholism" the cases where, for instance, a drinking bout preceded an ordinary attack of mania or melancholia. To bring out this point, I took the five last years (1903-1907) during which I was Physician-Superintendent of the Royal Edinburgh Asylum, when 450 of the 1,998 patients admitted had alcoholic causes, predisposing and exciting, but only 313 of those 450 had the special bodily or mental symptoms which we call "alcoholism." This gives only 70 per cent. of all the cases where alcohol came into the ætiology as being clinically alcoholism. The symptoms which I put down as specially characterising alcoholism or alcoholic insanity are hallucinations of the senses, morbid suspicions of a certain kind, confusion of a certain type, amnesia, certain forms of impulsiveness and loss of control, certain specific emotional and moral disturbances, mistakes of identities, alcoholic neuritis and paralysis, muscular tremblings, muscular inco-ordination, certain eye and facial degenerations, Korsakow symptoms, and such specific neurological disturbances. In short, I confined this class to the insanities where the brain suffered unmistakably from the distinctive toxic influences of alcohol. There is a great difference clinically between such cases of insanity and those where alcohol has come in as a mere upsetting cause, perhaps incidentally, the symptoms not having its specific toxic characteristics.

My studies and experience of the psychology and social effects of alcohol, and of the clinical symptoms it produces, have led me to one conclusion which I cannot sufficiently accentuate. It is this: that there is an extraordinary want of knowledge among the public, and especially among young men of all classes, as to its real effects. There is a lack of that effective realisation as to its risks which would make men careful about it, and thoughtful as to its use in their daily lives. I have elsewhere written about the importance of a "health conscience" being created in all men and women at an early period of their lives. You ask a young man if he thinks it quite safe to take a whisky-and-soda so often, and find that he knows nothing whatever about the scientific facts as to its potency or seductiveness. He is entirely ignorant of the effect of such a habit on his future life. To a large extent he runs risks through sheer ignorance. Because he feels strong and healthy, and because alcoholic drinks are pleasant and no immediate effects result at the beginning of their use, he will not really believe that there is any danger. Long before the alcoholic habit has been formed, or the mere desire has become a craving, is the time when such knowledge and such an alcoholic health conscience as I am speaking of would come in with good effect.

Dipsomania and Other Forms of Alcoholic Excess.

I do not now propose to go into the subject of the classification of the various forms of alcoholism, except to refer to that form which is usually called "dipsomania." The dipsomaniac has almost always a bad heredity, an unstable brain, and a lessened power of mental inhibition, before he takes to drink at all. He is apt to feel periodically depressed and out of sorts, he is a pleasure-lover, with little stability of character or settledness of life. He is very often of the artistic temperament; his sense of duty is weak, and he seldom sticks to any occupation or work long at a time. When he once begins to drink, his self-respect, his feelings of honour, and his natural affection pass away. He may have periods when he does not drink, and, in fact, when it is disagreeable to him, but those do not last very long, and usually follow bouts of drinking. The condition is incurable except in a few cases where recovery takes place at the end of adolescence, from 25 to 30 years of age. Compulsory abstinence alone prevents him from being a nuisance and a danger to society. He should not be allowed to propagate his species. If he does not take to alcohol, he often takes opium or some other drug. He is commonly a charming person socially, which adds to the risk.

The next form of alcoholism to which I would allude is that which is set up by the brain and bodily damage and exhaustion of severe diseases, such as attacks of insanity, tropical disease, etc., or by injuries to the brain. Frequently the cases in which an alcoholic craving is developed, even in those circumstances, are persons of an originally nervous temperament.

The third and last form of alcoholism which I would allude to is that which arises from the mere habit of taking alcohol, in an ordinary degree to begin with, but gradually proceeding to excess. It usually arises from ignorance or following social custom. There is no brain but may be damaged by the excessive use of alcohol, just as there is no human being that cannot be made drunk by a sufficient quantity of whisky. This habit form of alcoholism might certainly be prevented and extinguished if the knowledge which I have been preaching was acquired in time and used to rationalise the life.

There are two entirely different kinds of arguments in regard to the use of alcohol, either dietetically or as a luxury. The one is founded on the bodily, physiological, psychological, and medical considerations. The other is the altruistic, social, and religious. The one admits the pleasures and advantages, so far as they exist, but strongly points out the risks run and the precautions needed. The other kind could not be better stated than by St. Paul: "For through thy knowledge he that is weak perisheth." "Wherefore if meat maketh my brother to stumble, I will eat no flesh for evermore, that I make not my brother to stumble." He recognised the existence of "weak brothers," and their claims only. Modern science comes in by showing who is the "weak brother," and why he is weak.

A clinical fact of supreme interest from the medical and preventive point of view, which came out in my investigations into my experience, is that at least nine-tenths of my two thousand alcoholic cases who became insane had taken to drinking to excess before they were 25 years of age—in short, during the period of adolescence. Enough is now known of the physiology and psychology of this period of life to have led us to expect this result from any poisoning of the brain during the time it is developing. The brain cells of the adolescent are entirely unfit to tolerate alcohol with impunity.

Practical Conclusions about Alcohol from these Psychological and Clinical Facts.

(1) The action of moderate quantities of alcohol on mind differs in different individuals.

(2) Anything approaching excess is always deteriorating and dangerous to mind and body.

(3) Its chief action is always on the higher and more regulative of the mental faculties.

(4) It affects the finer muscular co-ordination even in moderate doses.

(5) Some qualities of brain are much more susceptible to its influence than others.

(6) Its pleasant personal and social effects can only be safely obtained in fully-developed, healthy men with a reasonably good nervous heredity, and taken in strict moderation.

(7) Its dangers should be made known to every citizen early in life.

(8) To the female sex it is especially dangerous.

(9) The period of adolescence is by far the most dangerous time of life in regard to alcohol, and therefore it should not be used then at all.

(10) A nervous constitution of brain and a bad nervous heredity imply a special susceptibility to its evil effects. Scientific facts would point to complete abstinence from it by persons with this constitution.

(11) Mental disease and defect would be diminished if alcoholic excess did not exist.

(12) Alcohol in excess predisposes to and causes many forms of bodily disease, and reduces the chances of recovery in all bodily diseases. Certain of its bad effects on the brain are probably harmful to descendants.

(13) Scientific facts point to a great diminution of alcoholic mischief if no alcoholic drinks containing more than 18 per cent. of absolute alcohol were used, except for medical purposes.

(14) New legislation is needed for those who labour under the disease of an uncontrollable craving for alcohol, and also to diminish temptations to its use.

(15) The most hopeful fact in regard to alcohol is that its excessive use has undoubtedly diminished in the last hundred years among the evolved, the educated, the reasonable, the well-off, and the self-respecting part of the community in all civilised countries. The increase of knowledge and of self-control, the lifting up socially of the poorer, the rationalising of our city life and conditions, the gratification of human nature's craving for happiness by the provision of healthy modes of life, amusements, good and abundant food, the practice of the rules of a scientific sociology, the wider knowledge of the dangers of alcohol, the efforts of our clergy, social workers, medical officers of health, the school medical officers, the segregation of the irreclaimable drunkards, and the diminution of bad nervous forms of heredity through the practice of eugenic laws, will no doubt help materially to bring in the era of a sober people.

THE SUPERVISION OF THE HEALTH OF CHILDREN BETWEEN INFANCY AND SCHOOL AGE. (a)

Report by W. W. James, F.R.C.S., L.D.S.,
London.

(Concluded from page 478.)

Deformity of the jaws associated with nasal obstruction can be seen at quite an early period. The lack of development is marked in the temporary dentition by the absence of spacing of the incisors; at times the incisors are crowded as if not only is there lack of development but active diminution of the arches. The latter might be accounted for by impaired development occurring prior to eruption of the temporary teeth, but this does not seem likely, as the incisors are chiefly affected and not the canines, which, erupting later, are found to take up their positions in the arch; the explanation is to be found, I think, in the absence of contact of the tongue against the palate, whilst the pressure from the cheeks causes lateral compression.

The protrusion of the maxillary incisors is another deformity seen in the temporary dentition. Should this condition coexist with the mechanical distortions described above it may be difficult to determine the more important factor.

The change in occlusion which, I believe, occurs in the process of normal development usually does not take place. Instead of the incisors biting edge to edge, those of the mandible continue to occlude posteriorly to the maxillary incisors, and they do not show attrition marks. A factor which may play a part in producing post-normal occlusion in these cases is mouth-breathing. Where the mouth is constantly open the muscles are at a disadvantage in supporting the mandible and the structures attached to it below. The weight of the pharynx and larynx constantly tend to displace the mandible in a downward and backward direction. In mouth-breathers where the jaws are not occluded, this force is sufficient to hamper advancement, or may actually cause backward displacement of the mandible. This view is introduced as it partly accounts, I believe, for the impaired respiration in mouth-breathers, the backward displacement of the tissues causing some obstruction. It is well demonstrated in patients under an anæsthetic, particularly in a sitting position, for if the mandible be pulled forwards respiration is markedly free, whilst backward displacement of the mandible with the mouth open causes marked obstruction. In the dead subject, when the muscles are quite passive, the mandible from the mere weight of the structures attached assumes a posterior position. A child whose mandible had assumed a post-normal position (associated with tongue-sucking) was advanced with such marked benefit to health that the father, a medical man, commented upon it. The greater freedom of respiration seemed to be the only explanation. The dental arches were well developed, and there was no nasal obstruction. It has constantly been stated that imperfect aeration of the blood is a result of nasal obstruction, and the view expressed above may be the true explanation, as apart from this there does not seem to be any reason why air should not enter as freely through the mouth as the nose.

(a) Paper read before the Joint Sections of Hygiene and Preventive Medicine and of Stomatology, International Congress of Medicine, August, 1913.

The teeth are more prone to caries in mouth-breathers, and inflammation of the soft tissues is likely to occur. Both of these are probably associated with the deficient bathing of the parts by the saliva. Further reference to the effects of nasal obstruction will be made later.

Constitutional Disturbances during infancy may have a marked effect upon the teeth; the effect upon the jaws is less easily proved, as other factors are usually present. The temporary teeth may be delayed very markedly in their eruption; they are often imperfectly developed, as has been stated already. In cases where dental caries is extensive a history of disturbed nutrition in very early life is frequent. Rickets and dental caries are usually associated. The very early eruption of the first permanent molars is not infrequently seen in rickets. In several cases these teeth have been present in children of about four and a half years; the condition in some of them resembled an exfoliation rather than an eruption—in all cases the tooth was imperfect.

Little can be done beyond improving the general health of the patient and dealing with the local conditions as far as possible.

During the period under discussion, between infancy and school age, deviations from normal development and other pathological changes comprise for the most part the continuation of the processes just described as arising during infancy. The various conditions can be discussed, for convenience, under the following headings:

Imperfect and Abnormal Development of the Jaws and Dental Arches.
Dental Caries.
Maldevelopment of the Teeth.
The more Uncommon Conditions.

Some reference must be made to imperfect development of the jaws and dental arches, although the subject has become so important that volumes might be written upon the views of different observers and the criticisms made upon them. Reference has already been made to some of the possible causes, for in nearly all cases they occur prior to eruption of the permanent teeth. Formerly malformations were dealt with when they were definitely established, but, with an increasing knowledge of the causes, the treatment and prevention of these conditions must pass to an earlier period.

Numerous classifications have been made of the types of maldevelopment, based chiefly upon the arrangement of the teeth; they have helped considerably to further knowledge, but at present none of them can be regarded as satisfactory.

If the jaws and teeth after eruption of the permanent teeth are not perfect in their development it must be due to a condition of either arrested or abnormal development. This clinical division is convenient as it emphasises the conditions found, but both are present in many cases. A satisfactory classification, it would seem, must be based upon primary causes when we possess sufficient knowledge of them.

That development of the jaws has been arrested in some degree is evident in many cases, for the teeth occupy positions in the arches similar to those which they occupied prior to eruption.

That abnormal development of the jaws occurs is also quite evident in a great number of cases, growth taking place, but in a position which can certainly be described as a deviation from the normal.

It is undesirable to labour these points, but it may be well to point out that deficient growth or abnormal growth can occur in three planes, laterally, antero-posteriorly, and vertically. Deficient growth in each direction is seen where the dental arches are too narrow, where they are short antero-posteriorly, and where the teeth appear to be only partially erupted. As the result of the arrested development of the jaws the teeth must take up the positions possible to them during eruption.

The erupting teeth can be divided into two groups, those which meet with no obstruction, and those which are obstructed by firmly implanted teeth already in position. The molars, the central incisors, and the first premolars belong to the first group, whilst in the second group the lateral incisors erupt between the central incisors and the temporary canines; the second premolars between the first permanent molar and the first premolar, and the canine erupts between the lateral incisor and the first premolar. The irregular arrangement of the lateral incisors and the canines is well known; the second premolar displacement is typical, but the tooth occasionally gains space by the forward movement of the first premolar at the expense of the canine, or occasionally the second maxillary premolar has preceded the first. Where the arches are only slightly deficient a variable degree of rotation of the teeth in the latter group is seen.

The eruption of the first permanent molars may be defective in a vertical direction, and, in my opinion, is often due to lack of development of the mandible, which is indicated by absence of the edge-to-edge occlusion of the temporary incisor teeth.

That the teeth may be large and the jaws small is a possibility, and may account for some of the cases which appear to be due to deficient growth.

The abnormal development of the jaws is well illustrated in cases where protrusion of the maxillary incisors occurs. the bone projecting with the incisors anteriorly and instanding at the sides, particularly in the premolar region, whilst the incisors of the mandible with their supporting bone are elevated above the level of the teeth behind them, their elevation being due to the lack of opposition of the maxillary teeth as they are found to occlude with the palatal mucous membrane.

In some cases, including those described as "open bite," deficiency of growth probably plays an important part, but impaired development, as in cases of rickets, may account for the condition.

Much discussion of the lines of treatment of these cases could be introduced, but here it must suffice to say that two methods may be adopted in many of the cases. The best results are usually obtained by increasing or altering the dental arches so that the teeth are correctly arranged, but excellent results can sometimes be obtained by extraction of some of the teeth.

The treatment in both cases should be commenced early. If expansion is intended correct occlusion must be established and the arches corrected by the use of apparatus. In the cases where extraction of teeth is to be undertaken the temporary canines should be removed to prevent the very common overlapping and crowding of the permanent incisors, and at a later stage removal of the maxillary first premolars and perhaps those of the mandible. The time of eruption of the canines is usually the best period at which to undertake the premolar extraction, the erupting tooth passing into the space made, whilst the teeth already erupted will probably not be affected. As a routine in hospital practice, the method just described is usually sound, although impossible in many cases. Each case demands individual consideration.

Dental Caries has already been referred to in the account given of temporary dentition, and much that has been said applies to the permanent teeth. The commonest site for its commencement is in the fissures of the crown of the first permanent molars, although it is not uncommonly seen on the surface of this tooth next to the temporary molar when the latter has a carious cavity on that side. Elsewhere, caries of the temporary tooth may cause the neighbouring tooth to become carious, as is seen in a first premolar from contact with a carious second temporary molar or canine; it applies particularly to "crowded" mouths.

Mouth-breathing is the most frequent factor in producing caries of the incisors at this period, although hypoplasia of the teeth may be almost as important. It is of interest that the two conditions are frequently seen together.

Dental caries affecting the first permanent molars is so common, and the tooth is so very important, that it might be regarded as the point upon which the whole of the present discussion, from the stomatologist's point of view, turns. In a great majority of cases the preservation of these teeth in a healthy state will render the establishment of a functional and clean mouth relatively much easier.

The eruption of the first permanent molars is very rarely recognised by the child or its parents, a fact of much significance as the tooth may be neglected in cleaning, and should it become carious, may be regarded as a temporary tooth and thought not to matter. Prior to exposure of the tooth in the process of eruption, the gum behind the last temporary molar is found to be full and often flattened by contact with the gum of the opposing jaw; later, the tissue is perforated by a cusp and the crown of the tooth becomes exposed; the rate of denudation of the tooth varies, being long delayed, for instance, in those cases where vertical development is imperfect, but rapid where the jaws are well developed. The degree of freedom of the tooth from overlying tissue is important, for if food can lodge caries will more readily occur. The great advantage of well-developed jaws is therefore evident.

The frequency of hypoplasia of this tooth as the result of disturbance in early life favours the induction of caries, although by removing the ragged edges of enamel and applying nitrate of silver caries may be prevented; but the application of nitrate of silver where softening is more than superficial is useless, and it is only too common to find extensive caries in teeth which have been so treated instead of being filled.

Commencing caries in the fissures of the crown should be most carefully sought for and fillings inserted. It is unnecessary at an early age to do more than fill the carious point of the fissure with a more or less temporary filling such as hard gutta-percha, cement, or copper amalgam and later fill the tooth permanently when the child is older and all the fissures can be cut out more carefully.

If the pulp is involved a most serious consideration has to be faced. The patient may be difficult to manage and treatment of the pulp almost impossible. The pulp might be capped, but this is a procedure which is too dangerous, for supposing it becomes infected in a few years, an acute alveolar abscess only too commonly results and the tooth must be removed, conservative treatment probably being impossible.

The questions, Can the tooth be saved permanently? Will the removal of the tooth cause serious malocclusion? are the two considerations upon which the decision rests.

If asepsis can be maintained the answer to the first question is almost certainly "Yes," unless the caries extends below the attachment of the gum at the neck of the tooth.

The second question can also be answered in the affirmative in almost all cases, the exception being where the jaws are small; in those cases where the teeth are large and the jaws small the resulting occlusion may be good. The general conclusion will favour the tooth being retained, but each case must be decided on its merits.

Caries in the maxillary incisors must be dealt with thoroughly; loss of the crowns is not uncommonly seen where fillings obviously have been inserted in cavities improperly prepared.

Premolars are not infrequently carious. In mouths with teeth very liable to become carious, if crowding be marked, extraction is likely to give the best result. All proximal cavities should be filled as permanently as possible whilst the tooth surface is accessible; the cavity has usually resulted from caries in a temporary tooth; the latter should be removed and the filling undertaken before the permanent successor erupts.

The subject of dental caries has perhaps received more attention than any other condition of importance to the dental surgeon. It is known to be directly due to the action of micro-organisms, although specific organisms have not yet been isolated. The process consists in the production of acids, chiefly lactic acid, from the carbohydrates of food causing decalcification of the tooth, and secondly in the destruction of the organic tooth substance by a process of peptonisation. The preventive measures suggested are many, and several are of undoubted importance.

With regard to the teeth themselves, their structure and arrangement can certainly be relatively favourable or unfavourable to caries. Recently it has been demonstrated that the enamel of the teeth varies considerably, and the terms "malacotic" and "sclerotic" have been suggested for the two marked types which have long been described clinically as "soft" and "hard," and that the enamel development could be influenced by functional activity during infancy. These views upon the variations in the resistance of enamel can certainly be supported by all who are acquainted with caries of the teeth.

The arrangement of the teeth is a factor which has long been recognised; caries always commences at points where food can lodge. If the teeth are irregularly arranged, food can lodge easily and caries eventually ensues. Functional activity to encourage normal development of the jaws must therefore be regarded as one of the defensive factors.

The natural processes by which cleansing and protection of the teeth should take place are of the utmost importance. They depend upon the nature of the food and local factors. Food which readily collects on the teeth, and particularly if it is not easily removed, must necessarily be a potent cause of caries. The prevalence of dental caries has been attributed to the increasing use of soft foods from which the fibrous elements have been removed; foodstuffs which possess fibrous elements are themselves not only easily removed, but they mechanically cleanse the teeth during mastication. The advantage of a diet which in itself cleanses the mouth—for the soft tissues will benefit as well as the teeth—is obvious.

The effect of the food upon the secretion of saliva is a factor recently brought forward, and most interesting experiments have been carried out to show the influences of many food substances. The results of these experiments prove that the salivary secretion varies in quantity and quality with the particular food taken, those substances having the most marked effect being the organic acids which occur naturally and substances which have definite flavours; diminished secretion results from substances which are alkaline or devoid of flavour. The saliva is regarded as a natural mouth-wash, and all its components are valuable in protecting the teeth. The ptyalin is regarded as chiefly of use in converting the carbohydrates which adhere to the teeth into a more soluble substance.

A local factor to which attention has not been drawn is the action of the tongue. That this is important in animals, such as the carnivora, will hardly be doubted, and that the surfaces of the teeth over which the tongue, lips, and cheeks readily pass are usually free from caries, is in some degree significant, although it is true food does not easily lodge upon these surfaces. Whether variation of the papillæ upon the tongue is related to the incidence of caries is perhaps worthy of investigation.

The further development of dental caries is certainly hindered by a complete eradication of carious lesions already present in the mouth. Patients who have suffered severely from caries may experience a long period of immunity if absolute elimination has been carried out; many observers must be able to bear out this statement from clinical experience. If this view is accepted dental caries must be regarded as an infective process.

A negative factor for the prevention of caries to which some importance has been attached is the exclusion of the carbohydrates which are most readily fermentable. It is urged that the increased use of monosaccharides, such as glucose, accounts for the great increase in caries. That children who eat large quantities of sweets may have extensive caries is certainly true, and in particular cases probably cause and effect are correctly associated.

Mouth-breathing has already been discussed in some degree, but one characteristic, gingivitis, which is most marked when the permanent teeth are erupted, must be referred to here. The gum-tissue in the front of the mouth, and particularly of the maxillary incisors, although other parts are also affected, show changes indicating chronic irritation, the parts are swollen, bluish or dark red in colour, dry or covered by inspissated mucus. The condition is obviously due to the drying caused by the constant flow of air over these tissues, and the absence of repeated bathing by the saliva which should occur normally. Dental caries is commonly seen in the maxillary incisors, and sometimes occurs in those of the mandible. The serious consequences which may ensue are such that every effort should be made to arrest the condition. The nasal obstruction must be removed and nasal respiration established. Breathing exercises must be practised, and should the mouth-breathing still continue at night, in spite of the efforts of the patient to control it, an apparatus should be worn. The apparatus used by the writer consists of a metal frame with thin rubber stretched over it, which is inserted inside the lips and cheeks and lying on the outside of the teeth and gums.

Every attempt must be made to keep the teeth clean; they should be scaled and polished, the cavities filled and regularly attended to by the patient and the dentist. Pyorrhœa alveolaris will certainly become established if this condition of gingivitis is not corrected. In addition to the regular cleaning by the patient, a valuable and simple method consists of massage of the gums by the use of a material such as butter muslin wrapped round the finger. Local applications of iodine, or very weak iodine as a mouth-wash are useful, but the teeth become badly stained. Hydrogen peroxide is perhaps the most useful mouthwash. Should the gingivitis have caused much swelling so that marked pouches exist between the gum and the teeth, a syringe with a fine nozzle should be used regularly.

Maldevelopment of the Teeth results from disturbance during the process of development; constitutional conditions such as rickets, syphilis, acute specific fevers cause hypoplasia, which is seen only too frequently. In addition to these, a local factor, severe inflammation due to infection of the tissues from a temporary tooth, ought easily to be prevented; hypoplasia of a single tooth is due practically always to this cause, and at times loss of the tooth has resulted by the inflammation leading to necrosis of the tooth or even of the jaw. In connection with hypoplasia, it is of some interest that the formation of enamel appears to continue almost to the period of eruption.

Of other affections space does not allow of their discussion, such as different forms of stomatitis, which may be severe; extensive suppurative conditions, particularly associated with the first mandibular molar; injuries to the teeth; the effects of completely misplaced teeth and many other conditions which may call for careful consideration.

The means which can be adopted by the patient and by the dental surgeon to maintain the mouth in a healthy state need only be outlined in most instances, as many of the methods of treatment have already been mentioned when the various pathological conditions were referred to.

In the first place, harmful habits must be prevented, such as thumb-sucking, teats, &c. It has been urged that a teat of a correct shape may be of value by inducing functional activity of the jaws and so aiding development, but the risk of establishing a bad habit is too great to justify its use.

The habit of grinding the teeth is often associated with well-developed jaws. It cannot easily be encouraged or discouraged, but that it is a common habit, and certainly appears to be beneficial to the child, makes it worthy of comment.

Food is a factor of the greatest importance. It should be of such a nature that the jaws and teeth are exercised and development promoted. The fibrous elements should not be removed, as they mechanically clean the teeth and stimulate the gingival tissues. Of all the means suggested for maintaining the mouth in a healthy condition, the presence of the fibrous elements appears to be the most important in its influence on the soft tissues. Some of the food at each meal should be of such a nature that the flow of saliva is stimulated. Harmful substances which stick to the teeth and are not easily removed should be avoided, or when eaten combined with and followed by beneficial substances such as raw fruit, &c. Sweets in large quantities certainly should be eschewed.

The habit of removing food from the teeth with the tongue is a valuable cleansing process, but one which can hardly be carried out except in private. Where the teeth are perfectly arranged in healthy individuals whose tissues possess vigorous tone, the tongue, cheeks, and lips probably constitute a most powerful influence in keeping the mouth clean.

In some children, especially girls with dry and sticky mouths, not infrequently it will be found that insufficient liquid is taken.

The mechanical cleansing of the teeth with a toothbrush is undoubtedly of great value. In the case of the temporary molars, if the biting surfaces of the crowns be brushed with a stiff-bristled brush caries may be prevented entirely, except in the case of children with mal-developed teeth. The particular directions with regard to brushing should be, "use a very short movement, brush one tooth at a time, commencing on the biting surface, brush all surfaces; the inner surface is more difficult to brush than the outer surface and so requires more care." Soap is an essential ingredient of a tooth paste or powder.

The duty of the dental surgeon comprises prevention of lesions which will cause maldevelopment, correction of conditions as they arise, and the removal of factors which will cause an unclean state of the mouth. Under favourable circumstances the teeth can be arranged in perfect arches with correct occlusion. If crowding of the incisors occurs after eruption and the arches cannot be expanded, the temporary canine teeth should be extracted to correct the overlapping which is so common in these teeth, and the subsequent deformity corrected later, probably by the removal of the first premolars.

Carious temporary teeth must be filled or, if the pulps are involved, extracted. The first permanent molars must be saved if possible, as their extraction is nearly always most disastrous.

Mouth-breathing must be corrected and the associated gingivitis carefully treated. Pyorrhœa alveolaris will arise where the gingivitis and mouth-beathing persists; irregular arrangement of the teeth is another predisposing factor which can be corrected in early life.

In conclusion, the great prevalence of dental disease clearly indicates that our knowledge of its prevention is but meagre. The difficulties of prophylaxis are indeed numerous; lesions may be found at so early a period that preventive measures are impossible, and at later periods others arise which at times are hopeless to deal with except by removal of the teeth. We are well acquainted with the great strides which have been made in conservative dental treatment. The work upon prevention of dental caries has been valuable, but is still undergoing the test of proof. So much is being done by organised effort on the part of public bodies that we can confidently look forward to wider organisation which will include research for prevention and systematic treatment of dental lesions. We can confidently say we have great hopes for the future.

OPERATING THEATRES.

WEST LONDON HOSPITAL.

Plastic Operation for Loss of Skin on the Dorsum of the Hand.—Mr. Aslett Baldwin operated on a girl, æt. 20, who had been knocked down in the street and the back of her left hand injured to such an extent that the whole of the skin on the dorsum and some of the tendons had sloughed. The hand had been treated with antiseptic baths and fomentations, the sloughs had come away, and the back of the hand was covered with a healthy granulating area. The operation was performed in order to cover this in with skin. Two vertical incisions, about four inches long, were made below the anterior part of the iliac crest on the left side; the incisions were three and a half inches apart. Between these a bridge of the whole thickness of the skin and a layer of the subcutaneous fat was raised. The girl's hand was pushed underneath this bridge of skin so that the whole of the raw area of the hand was covered, the fingers being drawn through the anterior incision and so were uncovered. Each end of the bridge of skin was now sutured with interrupted silkworm-gut sutures to the refreshed skin edge at the base of the fingers and at the lower end of the forearm. The operation area was painted with tincture of iodine and a white gauze dressing applied, which was held in position by a bandage. A plaster of Paris case was then applied, which included the pelvis and the left upper extremity, so that movement of the hand was prevented

Mr. Baldwin said that he considered Thiersch's method of grafting would have been unsuitable in this case, as it would not have provided a movable, sound covering for the back of the hand. A covering made in that way would probably have become firmly bound down, interfering with the movement of the tendons, and would have been constantly liable to ulceration owing to its position, which would expose it to frequent injuries. The method adopted would, if all went well, provide a covering of the whole thickness of the skin which would be movable over the parts beneath, and not liable to ulceration from injury or want of nutrition.

Operation No. 2.—In ten days' time the plastic case was removed and the sutured edges of skin were found to be united. An incision was made along the extreme upper end of the bridge of skin, and this was sutured to the refreshed skin at the right border of the hand. A dressing and plaster case were then applied as at the first operation.

Operation No. 3.—In about another ten days' time the same procedure was adopted at the lower end of the bridge of skin, and the hand thus freed from its attachment to the patient's body. As there was some pus about the large raw surface from which the skin had been removed, it was not deemed advisable to attempt to close this at once, but it was left for a future occasion.

Operation No. 4.—The wound having been treated with fomentations, and having become apparently aseptic, the skin all round it was undermined for a considerable distance till the edges could be approximated with only a moderate degree of tension. The wound was then completely closed with silkworm-gut sutures, some of which were inserted about an inch and a half from the edges of the skin to act as stay sutures and to relieve the tension on the others. This wound healed practically by first intention, and the girl left the hospital in about a fortnight's time with all the wounds soundly healed. On leaving the hospital the transplanted skin looked considerably thicker than that on the other hand, but Mr. Baldwin considered that this would greatly improve in appearance owing to the absorption of the subcutaneous fat and thinning of the skin.

The girl has been seen several times since the operations, and the appearance of the skin is gradually improving.

TRANSACTIONS OF SOCIETIES.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Joint Meeting with the Obstetrical Society held in the Royal Victoria Dispensary, on Wednesday, October 29th, 1913.

Mr. J. M. Cotterill in the Chair.

Major Leonard Darwin, President of the Eugenics Education Society, delivered an address on

THE NEED FOR EUGENIC REFORM.

The acceptation of the principle of evolution in recent times constituted a revolution in thought, and every revolution in thought was inevitably accompanied by changes in policy and social customs. It was impossible for them to go on acting as if they held the same views as their ancestors. It was the aim of the eugenist to hasten and guide the reforms in social customs and in legislation which must in any case result from the acceptance of the principles of evolution. If they pondered the state of affairs under the poor law, lunatic asylums, administration in regard to crime, the state of slums and so forth, there must be profound dissatisfaction with the existing condition of the country. Remedies must be sought in the ever-increasing knowledge of the laws of nature. Up to that time the efforts of the reformer had been almost entirely directed to conferring immediate benefit on man by altering his mental and physical surroundings. Without relaxing those efforts, they must also endeavour to ensure that their descendants should enter the world with a better equipment to fight the battle of life. They held that both the useful inborn qualities of man and his evil tendencies had been evolved in accordance with the laws of nature, and they hoped that by studying these laws, and by utilising the processes thus discovered by which man had been evolved from a lower type, they would be enabled to take steps tending to ensure that the man of the future should be a nobler thing than the man of to-day. There was danger in scientific dogmas which might entail the death of scientific progress.

Eugenists were not yet in a position to formulate a policy with great precision. There was much work to be done, but much uncertainty was clearing away. They saw clearly that the selection of the ancestry of a future stock was one of nature's ways of ensuring racial progress.

The work of the social reformer and of the student of heredity were both means of advance. The trainers of racehorses did not quarrel about good training or good pedigree. They required both, and in man both must be attempted.

There was already much for eugenists to do. Moral and legislative reforms and scientific investigation were required. Morals and science were the joint parents of eugenics. Galton's definition of eugenics was "the study of the agencies under social control that may improve or impair the racial qualities of future generations either physically or mentally." The meaning of a definition depended largely on the mental atmosphere into which it was received, and this definition would call to the mind of social reformers the "racial poisons," alcohol, contagious disease, etc. The evil effects of alcohol on the drinker and his family were unquestionable. but it was unknown how remoter descendants would be affected. The known facts, however, justified a campaign against alcoholism and disease. It was impossible to say how long the effects of better housing and sanitation would last and how far they would improve the racial characteristics of man. Pending further knowledge, their efforts must not be confined to the cure of faults of environment. They must look to heredity, which was the key by which the door leading to the further advancement of mankind might be unlocked. They might imagine all mankind arranged according to qualities thought desirable. It would thus be possible to divide mankind into those above the average and those below the average in civic worth. Their aim should be to decrease the rate of multiplication in the lower half and increase it in the upper half. But to make this practicable there must be a method of sorting out groups according to innate qualities, and at present they had no means of doing so. Neither poverty nor wealth was a certain criterion, but there was little doubt that the poorest group contained the highest proportion of biologically unfit, and yet they had the highest birth-rate in the land. The more capable classes being higher in the social scale had a greater distance to fall. This led to a prudent care for their own future prosperity, and the wellfare of possible offspring. Marriages were later and children were fewer. As possible stimulants to an increased offspring in the more capable classes, the income-tax might vary according to the size of the family, and death duties might be arranged in the same spirit. The pay of State employees might be partly dependent on the number of their children. Such expedients would only touch a few, and their main hope must rest on an improved mental attitude of the whole nation with regard to the duties owed to posterity.

A man who was not deterred from an improvident marriage by the prospect of want was not to be influenced by eugenic thought. The eugenist must deal with this class, and the interference was legitimate, since this class threw an immense burden of poor law responsibility, etc., on the community. Sterilisation of certain degenerates was now carried out in some of the American states. Segregation was within the range of practical politics since the passing of the Mental Deficiency Bill.

Habitual criminals and paupers judged to be degenerate by various tests should be dealt with as requiring protection against themselves, or for the purpose of protecting the community against present injury and future hereditary taint. On a foundation of scientific investigation they must build a moral superstructure, and here their greatest difficulties would be found. A deep sense of obligation to posterity must be fostered. The economist might aid in making known the burden thrown on the community by the presence in their ranks of vast numbers of degenerates, and the need of reform.

Increased taxation, often hidden in the form of increased rents, lowered wages, increased prices, diminished aid in times of trouble, lessened power of competition in peace and of defence in war, was the penalty they were now paying for the carelessness of their ancestors with regard to the purity of their race. Were they to be equally careless as regards the future? If they could only make the facts known, an appeal to their fellow-countrymen in the name of patriotism would attract enough recruits to their ranks to make the success of their cause a certainty.

On the motion of the Chairman, seconded by Dr. Haig Ferguson, a hearty vote of thanks was accorded to Major Darwin.

A provisional Committee, with Sir Thomas Clouston as Convener, was thereafter appointed, with a view to the formation of a branch of the Eugenics Society in Edinburgh.

LIVERPOOL MEDICAL INSTITUTION.

Meeting held Thursday, October 23rd, 1913.

The President, Mr. Robert Jones, F.R.C.S., in the Chair.

Mr. G. F. R. Smith read a note on the

ASEPTIC TECHNIQUE OF THE ANÆSTHETIST,

in which he insisted on the preparation of the patient's mouth, on the use of sterilised apparatus—namely, the mask and its cover, the bottle for the anæsthetic, gag, etc. Also the anæsthetist should wear a sterilised overall, cap, mask and gauntlets.

Mr. R. C. Dun spoke of the advantages of the method, especially in operations on small children, where the anæsthetist was of necessity close to the field of operation.

Mr. Thomas Guthrie read a note on

ENUCLEATION OF THE TONSIL.

Referring to the *technique* of the operation, he preferred the guillotine operation, introduced by Sluder in America and Whillis and Pybus in this country, for the great majority of cases. The method, however, failed in a few cases of very adherent tonsil, and in these he employed blunt dissection and a snare. Discussing the indications for the operation, Mr. Guthrie expressed the opinion that in cases of pure hypertrophy of the tonsils in children tonsillotomy was still the operation of choice, provided that not more than the capsule and a thin layer of tonsil tissue were left behind. In such cases, a tonsillotomy, properly performed, was almost always sufficient, and was a less severe operation than enucleation. Bleeding after the two operations was, as a rule, about the same in amount, but there was certainly more risk of troublesome hæmorrhage after enucleation than after tonsillotomy. When repeated inflammatory attacks had occurred, and the tonsil was grossly diseased, or was forming the portal of entry for glandular or systemic infection, enucleation was the only scientific and satisfactory operation. Lantern slides and specimens of tonsils and the instruments used were shown.

Dr. W. Sanderson, Mr. J. Bark, Mr. C. Yorke, Mr. E. M. Stockdale, M. Adair-Dighton, and Mr. Thelwall Thomas took part in the discussion.

Mr. Adair-Dighton read a paper on observations on the

DIAGNOSIS OF THE SUPPURATIVE DISEASES OF THE LABYRINTH.

After reminding members of the fact that one of them, Mr. Edgar Stevenson, had introduced labyrinthology into England as far back as 1896, Mr. Adair-Dighton demonstrated the tests upon a patient by means of the instruments of Brüning. He then took up in detail the various pathological divisions of labyrinthitis, together with the treatment of them. This completed, Mr. Adair-Dighton went into the differential diagnosis between labyrinthitis, cerebellar abscess, meningitis and tumour of the auditory nerve. To wind up, the author was of opinion that no operation, however small, should be undertaken upon the ear without the preliminary application of the functional tests.

Dr. Pantland Hick spoke of a case in which he had been associated with Mr. Adair-Dighton where a successful differential diagnosis of cerebellar abscess had been made by the Brüning tests.

Dr. Warrington said that whilst the nervous mechanism of the vestibular nerve and its relationships to the Deiter group of cells and oculomotor muscles was clearly known, the manner in which different kinds of stimuli excited the several semicircular canals, and so caused nystagmus in different directions, was difficult to follow so as to be able to apply readily in practical work. Further simplification of the *technique* was desirable, especially when it was necessary to examine persons who were ill with intracranial complications. He alluded to the rarity of cerebellar abscess compared with suppurative disease of the labyrinth, and urged the importance of diagnosis *inter operationem*.

Mr. E. Malcolm Stockdale said suppurative middle ear disease attacked the labyrinth in two positions—(1) the region of the promontory, (2) the external semicircular canal in the region of the antrotympanic passage. Total deafness on the affected side would suggest invasion in the cochlear region, and if the auditory apparatus was intact the application of the caloric test would decide whether the semicircular were active or not. If an erosion of the external canal was found during operation, it was usually advisable not to interfere with it. The radical mastoid operation on rare occasions was performed on patients suffering from meningitis. A preliminary lumbar puncture was most helpful in doubtful cases. Death from meningitis, following a radical mastoid operation, and due to lighting up a latent labyrinthitis, although it might occur, was extremely rare.

Mr. Edgar Stevenson and Mr. Hugh E. Jones also spoke, and Mr. Adair-Dighton replied.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Meeting held in Liverpool, October 17th, 1913.

The President, Dr. Fothergill (Manchester) in the Chair.

A selection of old illustrated works on obstetrics, including three copies of Raynald's "Byrth of Mankynd," were displayed by permission of the Hon. Librarian of the Liverpool Medical Institute.

Dr. Briggs (Liverpool) showed a collection of deformed pelves and a series of plaster of Paris casts of face presentations.

Dr. Fothergill (Manchester) showed a specimen of Cæsarean hysterectomy for fibroid. The fibroid was on the anterior wall of the uterus, low down, and completely prevented the passage of the head. Cæsarean section was performed, thereby saving both mother and child.

Dr. Gemmell (Liverpool) showed a fibro-myoma complicating the puerperium. The child was born without any difficulty, but symptoms of sepsis occurred on the third day, necessitating the removal of the necrosing tumour.

Dr. Oldfield (Leeds) read the notes of a case of bilateral ovarian cysts removed during the third month of pregnancy, which continued to full term. No signs of other ovarian tissue could be found in the pelvis and none was left from these two ovaries. For pregnancy to continue after removal of both ovaries is contrary to experimental evidence

Dr. Donald (Manchester) read the notes of a case of puerperal pyæmia, which continued five months in spite of Lantol and vaccines. At one time the patient developed all the signs of pelvic thrombosis, but none could be discovered on operation.

Dr. Fletcher Shaw (Manchester) showed a specimen of perithelioma of the uterus, which ocurred as a polypus, the size of a hen's egg, protruding from the external os. Two years previously he removed a simple fibroid polypus from the same uterus.

ULSTER MEDICAL SOCIETY.

Opening Meeting held in the Medical Institute, Belfast, on Thursday, October 30th, 1913.

Dr. R. W. Leslie in the Chair.

Dr. Leslie thanked the Fellows and Members for their kindness to him during his year of office. He introduced the President-elect and placed upon his neck the President's Badge, the gift of Sir Wm. Whitla to the Society. The badge had been presented to Sir William by the Ulster Medical Society in the year 1909, and was worn by him at all the official meetings of the British Medical Association which he attended as President. It has now been returned to the Society with the injunction that it shall be worn by the President of the Society during his year of office.

Mr. Mitchell then took the chair, and, having referred in sympathetic terms to the loss which the Society had sustained by the death of Dr. C. E. Shaw, he proceeded with his introductory address on

INCAPACITY FOLLOWING INJURY.

The paper was illustrated by a series of lantern slides, which showed how much a hand may be maimed and yet retain the decorative painter's delicacy of touch or the quay labourer's power of grasp. The paper dealt with the relations subsisting between the profession, the patient, the public, and the insurance corporations. He pointed out the great value of X-ray photography to each of these classes, more especially to the last-named, who are still largely dependent for their X-ray photographs on the work done in charitable institutions. Mr. Mitchell urged the importance of placing the purely photographic side of X-ray work within the reach of the general practitioners, and at a fee within the resources of the average artisan. He then directed attention to the gradual lengthening of the period of incapacity after injury following the introduction of the Workmen's Compensation Act, 1906.

Sir Wm. Whitla proposed a vote of thanks to the outgoing President. He also proposed that the President be thanked for his interesting and thoughtful address. This was seconded by Prof. Sinclair, and passed unanimously.

The President then proposed that the recommendation of Council "That Dr. J. Walton Browne be elected an Honorary Fellow of the Society" be passed.

This was seconded by Sir Wm. Whitla, and passed unanimously.

FRANCE.

Paris, Nov. 1st, 1913.

Hæmorrhage in Throat Operations.

The ablation of tonsils and vegetations from the back of the throat is an operation of daily occurrence, and the hæmorrhage that may result interests both the specialist and the practitioner. The hæmorrhage may be primary or secondary, but generally it ceases spontaneously, nature having provided the vessels with elastic fibres that provoke contraction and endow the blood with substances which favour coagulation.

Primary hæmorrhage after the employment of the amygdalotome will only occur in cases where the vessels remain patent (sclerosis), where important organs have been wounded (tongue, large artery, uvula), or in such rare cases as diminished coagulability of the blood (hæmophilia). Secondary hæmorrhage sets in on the third or fifth day, and is due to a too early detachment of a clot, the infection of the wound provoking increased tumefaction of the tissues, thus increasing the volume of the vessels.

The treatment, says Dr. Doulcet, consists of a variety of means and measures which can be successively employed as needs be, the first of which is ice. The patient will be told to swallow, not suck, small pieces of ice. In many cases this treatment suffices, but sometimes it fails, when recourse will be had to gargles of a solution of antipyrine or oxygen water, touching the parts at the same time with animal serum (hemostyl, or the serum of Roux). Turpentine has been employed in the same way. Where all these fail, there remains another resource to the practitioner—that of his fingers. A plug of cotton wool powdered with antipyrine or steeped in oxygen water is placed on the bleeding tonsil and kept *in situ* with the finger. The hæmorrhage ceases in the majority of cases. If it returns after the finger is removed a compressor might take the place, the simplest of which is the sugar tongs with a piece of string tied round the branches to maintain the compression. At the same time an ounce of anti-diphtheritic serum is injected subcutaneously, and where it is possible a bleeding vessel is pinched up with an artery forceps.

Hæmorrhage after removal of vegetations may also be primary or secondary. The first duty of the operator is to examine closely the region, as frequently a morsel is only semi-detached, maintaining more or less patent a small artery. Once nipped off, the bleeding ceases. Ice should also be given. At other times nothing remarkable is observed, and yet the hæmorrhage continues. Insufflation of a hæmostatic powder cannot reach the seat of the hæmorrhage; recourse must be had to pouring through the nose, the head being held backwards, a solution of antipyrine or oxygen water, while animal serum is injected hypodermically. If this treatment fails, the nose and pharynx must be plugged.

As regards the prophylaxy of the hæmorrhage, the operator will bear in mind that any acute inflammation (tonsillitis, coryza) should exclude for the time being any interference, also, in females no operation will be done in the week preceding and following the menses. The patient or his parents will be closely questioned as to the possible existence of hæmophilia.

Local Anæsthesia.

Prof. Réclus, the great partisan of local anæsthesia, employs at present the following solution:—

Physiological serum (7-1000), 100 grms.
Novocain, 0.50 centigr.
Solution of adrenaline (1-1,000), 25 min.

A syringe holding two cubic centimetres is used; as many as 45 syringes may be used if necessary in the course of an operation. The solution cannot be sterilised by heat, as heat decomposes the adrenaline, hence it is preferable to add the adrenaline to the solution at the moment of using the mixture. Each layer of tissue must be anæsthetised as the operation proceeds. Thus for the radical cure of hernia, the skin is anæsthetised with six syringes of the solution, the cellular tissue with four of five, the aponeurosis of the great oblique muscle with five syringes, and the tissues surrounding the sac and the cord with four syringes.

In operations on the fingers (whitlow, etc.), a ring of anæsthesia is made around the base of the organ, but here, as in all other regions, it requires ten minutes for the anæsthesia to be complete. The vaso-constrictive action of adrenaline renders the operation almost bloodless, no plugging being required.

GERMANY.

Berlin, Nov. 1st, 1913.

At the Medizinische Gessellschaft Keil, Hr. Birk brought up the subject of

Purgatives and Astringents in Children.

The speaker mentioned it as a fact that as good as no purgatives and astringents were given in the clinics and polyclinics. In the case of infants a strict distinction must be made between children brought up at the breast and those fed on artificial foods. The diarrhœas that appeared in the new born as the commencement of sepsis did not come into consideration as far as the administration of medicaments was concerned. The alimentary disturbancees of breast children depended mostly on over-feeding, for which reason in the milder cases it was sufficient to limit the number of times at which the child was put to the breast; in the severer cases a teaspoonful of castor oil and keeping the child from the breast for 24 hours sufficed. With children with an exudative diathesis one frequently observed a tendency to dispeptic evacuations, in spite of breast feeding. Here the speaker was rather in favour of a calm expectancy than an injurious polypragmasy with drugs. The constipation of infants appeared to be dependent to a great extent on thorough digestion of the milk of the mother. In somewhat more obstinate cases, mild laxatives (Califig., castor oil) were preferable to enemata, which were a constant trouble both to mother and infant. In the digestive disturbances of artificially fed children, calomel formerly played a chief *rôle*. The speaker rejected it entirely, as its action was unreliable, and a deal of mischief had been caused by it in families.

The acute disturbances of digestion were caused by far the most frequently as a result of fermentation of the bowel contents, and the most dangerous agent was apparently sugar of milk. For that reason it had been the aim of his treatment to stop fermentation by dietetic measures. The speaker here warmly recommended Finkelstein's albumen milk, which was the best astringent remedy. The constipation caused through milk feeding was best met by malt soups, purgatives, on the contrary, were contra-indicated.

In the case of older children, diarrhœa was properly treated by the astringent action of fruit soups, and in cases of habitual constipation by dietic measures without the aid of either purgatives or astringents.

Hr. Stoeckel showed two gravid females suffering from

Pyelitis Gravidarum.

In the first case pneumonia and then typhoid were thought of until an examination of the urine brought to light colon bacilli in the urinary tract and showed that the case was one of pyelitis. In that case the symptoms were very severe and medical-dietetic treatment with rest in bed were not sufficient to bring about recovery. Threatening symptoms made their appearance that pointed to general infection, and especially a pronounced icterus. The kidney was very sensitive to pressure, increased in size, so that a strong suspicion was aroused of paranephritic suppuration. In this condition the patient was passed on to the women's wards, as the interruption of the pregnancy came into consideration. The pregnancy was of the fifth month, and by washing out the pelvis of the kidney the disease was so favourably influenced that the pregnancy was allowed to proceed, the fever disappeared, and the patient's general condition became normal. The case showed that by local treatment the end could be attained notwithstanding a serious general condition. It showed also that for the attainment of that end washing out of the renal pelvis must be repeated time after time if necessary. In that case the kidney was washed out for weeks with intervals perhaps of a day now and again. There was no difficulty in carrying out the procedure. The patient was still a little jaundiced, but out of bed and free from fever; the pregnancy was also progressing naturally.

The second case was at first sent into the surgical clinic with a diagnosis of perityphlitis, which frequently was apt to be confounded with pyelitis. Here a single washing out was sufficient to bring about recovery.

The early diagnosis of these cases was of prime importance if the proper programme was to be carried out: cure of the pyelitis without causing any interruption of the pregnancy. In any febrile case during pregnancy when there was any point of tenderness anywhere in the neighbourhood of McBurney's point, either on one side or on both, and there was tenderness also in the region of the kidney, the urine should be submitted to bacteriological examination, the urine to be withdrawn with the catheter. With the presence of bacillus coli with pure cultivation or accompanied by other germs, the diagnosis was tolerably certain. Catheterisation of the ureter furnished complete assurance, and it also at the same time gave the stagnated urine the opportunity of finding an exit. It was without question true that many cases recovered by dietetic measures and rest in bed, but it was equally certain that many cases were allowed to get worse by delay, so that the structure of the kidney was injured and surgical measures became necessary, and the pregnancy was interrupted by abortion. It was only by the timely use of Lenhardt's medicament-dietetic treatment, accompanied by washing out of the pelvis of the kidney that infection of the system could be avoided and the pregnancy saved.

AUSTRIA.

Vienna, Nov. 1st, 1913.

Pathological Theory of Diabetes Mellitus.

The theory of diabetes mellitus enunciated by Dr. Frank is now the subject of considerable discussion. This author upholds the view that both the leading conceptions of the nature and origin of diabetes, although apparently so antagonistic, can really be traced back to a single primordial source. This convergence of pathological views becomes possible if we regard glycogen as the intermediate stage in this connection, and recognise the condition of glycosuria as that of a "pathology of glycogen." Glycogen is frequently regarded as an inert reserve stuff, which is simply stored up in the cells; but Ehrlich has emphasised the view that it is linked up with a transmitting substance, and Arnold has demonstrated the fact of its attachment by a definite relationship to the plasmosomes which are present in the hepatic cells. As a net result, we have reached a biochemical viewpoint which favours the conception that it is not so much to the grape-sugar that we should look, but rather to the glycogen, which is made the subject of molecular change in the course of the metabolism of the liver cells themselves. We know two modes of consumption of glycogen in the liver: the ordinary process, which follows hyperglycæmia; and another, that occurs in poisoning by phosphorus, arsenic, or sublimate, which runs a very rapid course of a few hours, without inducing the slightest alteration in the proportion of sugar in the circulating blood. Obviously, the influence of the poison leads to the rapid consumption of the glycogen contained in the cells. Embden had shown that the complete removal of blood from a liver rich in glycogen leaves behind large quantities of lactic acid; while a small quantity only of this compound is produced by the artificial transmission through the vessels of a liver poor in glycogen of a current of blood rich in grape-sugar. The formation, in a liver drained of blood, of a large number of substances containing azoto-acetic acid can be completely prevented by furnishing the injected liver with a rich supply of glycogen; while the addition to the artificial blood-stream of a quantity of grape-sugar, with a corresponding object, is absolutely ineffective. Embden also points out that the glycogen in the liver cells appears to be chemically more easily assailable than grape-sugar. Dr. Frank believes that the glycogen is attached to the living protoplasm—"vitally fixed"—possibly linked up with a phosphorus-holding complex—the carbohydrate-phosphoric-acid skeleton of nuclein, which, according to Embden's latest researches, would indicate an origin from muscle cells; or, as had previously been thought, in connection with the formation of carbohydrate-phosphoric-acid compounds in the catabolic products which precede the production of sugar. The pancreas would count for something in the regulation of the transmitted glycogen according to this view; the function thereof with those of the liver and emunctory organs dovetailing in the chemism of the living substances of the healthy organism. When this intermediate link fails, the glycogen, having no longer any capacity of fixation, is wholly exposed to the diastatic influence of the cells, and is thus rapidly transmuted into the very unconvertible and unprofitable grape-sugar. The hepatic cells, on the failure of the glycogen supply for their own functional processes, begin to form this very necessary compound from other materials—albuminous *débris*—but always uselessly, as they are unable to fix it under the abnormal conditions. This is the apparent explanation of the deleterious effect of a copious supply of albuminous nutriment, especially of flesh meat, in such cases. The healthy function of vital fixation has failed, and the use of large quantities of meat, in addition to carbohydrates, in the diet of diabetics is shown to be deleterious, by the relatively favourable course of clinical events in the co-called "carbohydrate cure." The grape-sugar passes, in the new conditions, from the liver and muscular system into the circulating blood, and thus produces the familiar condition of glycosuria. The supply of carbohydrates to liver and muscle cannot be turned to good account without intermediate incorporation as glycogen. In presence of this law, the opposition of the two compounds, of which the evidences are so manifest in the human organism, has its significance transferred to a higher plane of unity, and we find a common explanation of the mischievous effects of the dietetic use of sugar by diabetic patients, as well as of the failure of sugar metabolism and the excessive production of sugar in the diabetic organism. Unfortunately, we have as yet attained to no insight into the nature of the process by which vital fixation of the glycogen in the healthy body is effected by the action of the very important pancreatic hormone, nor into the cause of the failure of its physiological production which leads to all the phenomena of diabetes mellitus.

Sir Rickman Godlee, P.R.C.S., accompanied by Lady Godlee, has left for Chicago where he is to give an address at the first congregation of the American College of Surgeons and admit about 1,000 Fellows of the new college.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

The Inclusive Fee in Medicine

The chief item of interest in the billet summoning the statutory half-yearly meeting of the General Council of the University is the report of the Sub-Committee on the Inclusive Fee in Medicine. The objections are stated from the points of view of the Universities and from the point of view of the Extra-Mural Schools. From the University point of view the condition of uniformity is the chief objection, which would make it very difficult to increase a fee, as this would mean getting the consent of all four Universities. Practically, when an inclusive fee was fixed it would have to remain at the same figure. At present the General University Fund is made up of endowments, fees, and Government grants. The first are not likely to increase, as new endowments are nearly always earmarked for special purposes. Every new endowment increases the demand on the General Fund for equipment and other expenses connected with the development of a new lectureship or professorship. The charges on the fund are always increasing, and the only source of revenue which can be expanded is the fee fund. Now, the fee fund could not, under the inclusive fee, be increased either by adding new fees or raising old ones, but only by an increase in the number of students, which is at least problematical. Hitherto the general fund has increased chiefly from this source. The recent increment from Treasury grants is fixed, and is the outcome of prolonged agitation; it has no immediate prospect of being increased. Should an inclusive fee be adopted, endowment for new chairs or laboratories would be a financial embarrassment instead of a gain. What is really required is that the Treasury grants should be reconsidered from year to year, according to what efficient teaching demands. At all events, some new method of financing the Universities will have to be found if the uniform inclusive fee is made a permanent feature in their administration. From the extra-mural standpoint the objection to an inclusive fee is that it would tend to result in the students taking all their classes in the University and the reduction in the extra-mural students would interfere with the initiation of new classes, would abolish the healthy rivalry between intra and extra-mural lectures, would check the supply of teachers, all of which would react unfavourably on post-graduate teaching and research. At the meeting of Council it was explained that the whole question of the inclusive fee was at present under the consideration of a special committee of the University Court, and that it was not desirable at present to discuss the matter in Council.

Working of the Insurance Act in Scotland.

Mr. Leishman, chairman of the Scottish Insurance Commission, addressed the first meeting of the Scottish Association of Insurance Committees on this subject in Glasgow last week. He spoke optimistically of the little friction which had attended the introduction of the Act, and ascribed this to the labours of the various Insurance Committees. In Scotland there were nearly one and a-half million insured, which represented 99½ per cent. of the total insurable persons. The deposit contributors numbered 36,000, and this class was both much smaller than what had been expected and also differed in character from what they had anticipated. Broadly speaking, it consisted almost wholly of good lives. Deposit contributors had drawn out only £800 in sickness and maternity benefit during the year, and there would therefore be a large surplus; it would obviously be good business for the societies to get hold of these people. They now had over £3,000,000 in the insurance fund, and had paid out just over a million. He expressed himself as satisfied with the state of the panels, and with arrangements for mileage; but thought that the arrangements as to prices of drugs would require revision. The Commissioners were highly pleased with the way sanatorium benefit was being worked. Over 2,000 people had been recommended for treatment, of which 75 per cent, had been dealt with in sanatoria, 6 per cent. at dispensaries, and the rest at home. The penny for research was being devoted entirely to that purpose.

Per contra, as the phrase goes, the inhabitants of the village of Stow are not satisfied with their money's worth. The Stow doctor will not go on the panel, and the Insurance Commissioners refuse to provide a resident substitute, but are allowing the insured in Stow to trust to the services of the Lauder doctor, who lives several miles off, across hills which the winter snows often render impassable. At a meeting held in Stow last week it was decided to petition the local Insurance Committee anew to make some other arrangement.

Dr. A. K. Chalmers, Medical Officer of Health for Glasgow, read a paper, on October 17th, at a meeting of the Glasgow School of Social Study and Training, held in the University. His subject was

The House in Relation to the Health of the Inhabitants.

The chief requirements, he said, were fresh air and sunlight. Although the characters of fresh air were somewhat elusive, the question of impurity in the air derived from respiration had a fairly definite meaning, and it lay at the foundation of the defective ventilation of houses. If a person from the open-air entered a room and found it "close" or "stuffy," the limit of permissible impurity had been reached, and the carbonic acid had formed at least 6 instead of 4 in 10,000 volumes of air, which was about the amount usually present in outside air. There were many other forms of impurity diffused and suspended in the atmosphere, both gaseous and solid, derived from combustion and from many manufacturing processes. Notwithstanding these and many other sources of impurity, the diluting power of freely moving air was very considerable, and the difference between the atmosphere of the country and that of a town was less than might be expected. In confined spaces, however, the results were very different. The amount of fresh air required per adult per hour was 3,000 cubic feet; that meant that, in a space of 1,000 cubic feet, the air required to be changed three times per hour to supply one adult with the amount of air necessary to keep the air rendered foul by respiration at the limit of admissible purity. A change of three times per hour was all that could be borne without perceptible draught, as that was practically attainable under natural means of ventilation.

The diploma of the late Dr. Elizabeth Blackwell, the first woman placed on the Medical Register, has just been presented to Queen Margaret College, the women's branch of Glasgow University, by Miss Barry, her adopted daughter. The diploma was obtained by Miss Blackwell at Geneva, in the United States, in 1849, and was registered in the British Medical Register on the earliest possible day—namely, January 1st, 1859, when the Register began.

Sir George T. Beatson, K.C.B., who retired from the active staff of the Glasgow Western Infirmary some months ago, was last week presented with a rose bowl and ornaments by the superintendent and the past assistants and house surgeons with whom he was associated in the Infirmary, in recognition of their high appreciation of his services. Sir George has been appointed to the honorary consulting staff. His successor on the active staff is Dr. G. H. Edington.

BELFAST.

Tuberculosis Medical Officer for Belfast.

At a meeting of the Council of the County Borough on the 28th inst., Dr. Andrew Trimble was appointed to the above post. There were sixteen candidates for the post, but it was generally known that the contest lay between two local candidates. The successful candidate, Dr. Trimble, resides in Belfast, where he has been in general practice for over eighteen years. For five years he was a member of the Council of the County Borough. He resigned this position six months ago, he is a graduate in medicine, surgery, and obstetrics of the Royal University of Ireland, and was placed in the upper pass list at his final examinations. In addition, he possesses the Diploma in Public Health of the Queen's University of Belfast. Dr. Trimble is at present a member of the Belfast Insurance Committee which administers the sanatorium benefit to insured persons. In order to obtain special experience he took a course of study at the Brompton Hospital for consumption. He also attended at the Frimley Sanatorium in order to make himself familiar with the method of treatment by graduated labour. He worked for a time under Sir Robert Philip, of Edinburgh. Dr. Trimble has also had experience as tuberculosis assistant at the Belfast Hospital for Skin Diseases, and worked for three years in the bacteriological laboratories of the Queen's University. We congratulate him on his appointment, and from what we know of his energy and efficiency we believe he will justify his selection to such an important post.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents]

TREATMENT OF FRACTURES OF THE BASE OF THE SKULL.

To the Editor of The Medical Press and Circular.

Sir,—I have read the clinical lecture of Professor Leon Bérard, which appeared in your issue of October 15th, with much pleasure. In well-marked cases of basic fracture, when the symptoms are prolonged with more or less insensibility, restlessness, stiffness of the neck, muscles, and elevation of temperature—provided the condition of the patient is sufficiently good to permit operation—he recommends free bilateral subtemporal trephining with drainage of the subarachnoid space. In other cases of suspected fracture of the base, in which there is no flow of cerebrospinal fluid from the nose or ears and no marked facial paralysis or loss of power of the external oculomotor nerve, he suggests lumbar puncture, performed with every precaution, to improve the pulse and respiration, and to relieve intercranial pressure.

The remarks of Professor Leon Bérard on the after results of severe head injuries I am able fully to accentuate. There is an absolute necessity in all cases for a long period of rest and careful living. I have patients still under observation whose lives have been saved by surgical treatment, and who, after long periods of convalescence, are still suffering from loss of nerve power and incapacity for any mental concentration, so that they are quite unable to follow their former occupation.

I am, Sir, yours truly,
J. Ward Cousins.

October 25th, 1913.

THE ETHICS OF JOURNALISM.

To the Editor of The Medical Press and Circular.

Sir,—The following are the opening sentences of an editorial statement in *The Times* of Monday, October 27th:—

"In *The Times* of Saturday was published a protest from a number of prominent advertising agents against certain circulars recently issued to advertisers by Reuter's Agency. These circulars, which emanated from 'Reuter's Financial Publicity Department,' suggested the advantage of dealing with an agency which had 'intimate relations with the Press,' and could secure 'extended editorial reference' to the affairs of its clients. The Assistant Secretary of Reuter's has now replied to the charge of our correspondents in a letter which, while undertaking to prevent 'misconception' in future, seems at the same time to show a complete misunderstanding of the vital principle at stake."

The correspondence, stimulated by this statement, that has appeared in *The Times* during the past few days tempts me to crave a little space in your pages. The subject closely concerns the medical profession, especially in regard to newspaper puffs of fraudulent quacks and quack preparations. I do not, of course, include *The Times*, which sacrifices thousands of pounds a year by declining this nefarious business. But other leading newspapers, which have on their staffs regular medical contributors, and have constantly thrust before their eyes authoritative evidence of the character of the traffic they are abetting, are not ashamed to derive great incomes from these foul sources. Such conduct of so many leading papers supplies the excuse to the poorer classes of journals in descending still lower and adding their editorial endorsement to the false statements of any financial or medical impostor prepared to pay the price.

The *Westminster Gazette*, like *The Times*, is among the considerable number, albeit minority, of papers that keep their advertising pages clean. Some few years ago it published a protest, like that now appearing in *The Times*, against the suggestion that a theatrical manager advertising largely in its pages should be spared adverse criticism of his plays. The advertiser evidently imagined that in paying for advertisements he was at the same time paying for gratuitous puffs; this probably had been his experience with less honourable papers. The *Spectator* is the most distinguished among the weekly papers that reject every form of objectionable advertisement. It is extremely jealous of the honour of the newspaper Press. It is, however, unfortunate that papers like the *Spectator*, whose withers are unwrung, seem all averse to doing anything to irritate the galls of their less happy brethren.

Almost unconsciously in the course of the two score years during which I have been giving attention to the subject of medical quackery I have accumulated a great store of knowledge bearing on the ethics of journalism. My writings in the medical and lay papers had, I suppose, led the profession to regard me as somewhat of an authority on the subject, and, much to my surprise, a year or so ago I was invited by the British Medical Association to give evidence on this special matter before the Select Committee on Secret Remedies and their Advertisements. I supported my evidence by a collection of leading articles, showing the knowledge of editors, and by fraudulent advertisements and puffs gathered recently from every class of paper. I believe I demonstrated the truth of the allegations I have now made, and showed that the attitude of the great bulk of the periodical Press in relation with gross and palpably fraudulent quackery forms one of the greatest scandals of the present day. For, as I have so often pointed out, it must be always borne in mind that all these papers set themselves up as censors of morals and guardians of the welfare of the people, and that the poor and ignorant take the appearance of an advertisement in their columns as a guarantee of the *bonâ fides* of its author. Many of the facts I refer to must be known to the majority of advertising agents, and it is not to be wondered at if some of them take for granted the unscrupulous character of many newspaper proprietors. If great and honourable daily papers like *The Times* and *Westminster Gazette*, and leading weekly journals like the *Spectator*, wish to escape from the perfectly undeserved stigma involved in classification among the herd of ignoble papers that order their business methods on the basest form of commercialism, they must set to work to expose, denounce, and put an end to the evils I have now tried once more briefly to indicate.

I am, Sir, yours truly,
Henry Sewill.

The Old Rosery,
Earlswood Common.
October 27th, 1913.

OBITUARY.

DR. LINTON, EDINBURGH.

Although it is now eight years since Dr. John Linton left Edinburgh, on his retirement from practice, he is well remembered by many friends and patients, who deeply regret the news of his death, which took place at Kinghorn on October 25th. He was born in 1838, and was educated at George Heriot's Hospital, and took his degree at the University in 1861. He practised in Edinburgh for more than forty years, and was beloved by an unusually large clientele of patients, whose interests were his sole care. It is reported of him that for ten years he took no holiday; and that he had neither the time nor the inclination to send out accounts and collect fees. In his early years he assisted Matthews Duncan, then at the height of his popularity, and this no doubt turned his thoughts towards midwifery. At one time he had an enormous obstetric practice. In a single year he attended 460 confinements, and in all he brought into the world some 10,000 infants. From 1868 to 1879 he was a physician to the Sick Children's Hospital, but apart from this he had no important appointments. Dr. Linton had a commanding presence and a calmness of manner which inspired confidence in many a sick room. Constantly pressed by work as he was, he had the gift of never appearing hurried. Dr. Linton married late in life, and is survived by a widow and one of his daughters. He was a doctor of the old school, and, although such a practice as his could scarcely ever be carried on now under modern conditions he represented a tradition which will be respected and admired by all who came in contact with him. He was a man of simple, straightforward character, upright in all his dealings, thinking little of himself and much of his patients, and ever generous to assist the poor and needy.

DR. H. F. PARSONS, OF CROYDON.

The death took place last week, at his residence in Croydon, of Dr. Henry Franklin Parsons, formerly of the Medical Department of the Local Government Board, aged 67. The deceased was the eldest son of Mr. Joshua Parsons, of Beckington, Somerset. He studied at St. Mary's Hospital, obtaining numerous prizes and distinctions, including the gold medal at the D.P.H. examination in 1876. He qualified as M.R.C.S., L.S.A., in 1867, becoming M.D.Lond. in 1870. He was an examiner in Hygiene and State Medicine for the University of London, and for the Diploma of Public Health at Cambridge. After being in private practice for a few years, he was appointed Medical Officer of Health for the combined districts of Goole and Selby in 1874. Five years later he became a medical inspector of the Local Government Board. His connection with the Local Government Board closed early in 1911, when he retired under the age-limit regulation of the Civil Service. Dr. Parsons served on a great many Departmental Committees, including that on water, gas, regulations as to cremation, the work of the geological survey, and the medical inspection and feeding of children in public elementary schools. He contributed papers to the "Transactions" of the Epidemiological Society, of which he became President, and to those of other scientific bodies. He was a Fellow of the Geological Society, and among his works were memoranda on the sanitary requirements of cemeteries, disinfection by heat, a report on the influenza epidemic of 1899-90, and an examination of the comparative mortality of English districts.

He married, in 1879, Louisa Anne, eldest daughter of the late Mr. John Wells, of Booth Ferry House, Yorkshire.

MR. E. NETTLESHIP.

We regret to announce the death of Mr. Edward Nettleship, the well-known ophthalmic surgeon, which took place on the 30th ult., at his residence, Longdown Hollow, Hindhead, aged 68. The deceased, who qualified in 1867 as M.R.C.S., L.S.A., became F.R.C.S. in 1870. He was one of the six sons of Henry John Nettleship, solicitor, of Kettering. At first he went to the Royal Agricultural College, Cirencester, and the Royal Veterinary College, and qualified as M.R.C.V.S. He also studied at King's College and the London Hospital Medical Schools. A highly-trained and indefatigable worker, Nettleship rose to great eminence in his special branch of surgery, but at the height of his fame he retired from practice to devote himself to the study of heredity in the causation of disease. To this subject, which had interested him throughout his career, he devoted his indomitable energy and produced much work, the value of which was recognised last year by his election to be a Fellow of the Royal Society. At the recent International Congress Mr. Nettleship made some important communications, and appeared to be in his usual good health; his unexpected death will therefore come as a severe shock to his many friends and admirers. His successful career was due to the minute and accurate observation which he bestowed upon every case, and this care never relaxed. As Consulting Surgeon to the Royal London Ophthalmic Hospital, Moorfields, and Consulting Ophthalmic Surgeon to St. Thomas's Hospital his services were highly valued. The numerous contributions which Mr. Nettleship made to medical literature will keep his memory green in the ophthalmic world, where the "Nettleship Medal," created in his honour, is the blue ribbon for which the younger members strive.

Mr. Nettleship shared the great taste for and love of music which seemed to be hereditary in his family. He married, in 1869, Elizabeth Endacott, daughter of Mr. Richard Whiteway, of Compton, Devon, but leaves no issue.

SPECIAL REPORTS.

THE IRISH MILK SUPPLY.

THE report of the Viceregal Commission on the Irish Milk Supply was presented a few days ago. The report, which is unanimous, is to the effect that from a variety of reasons the growing up generations are not obtaining that modicum of milk that is necessary for bringing up healthy children. The Commission was appointed by the Lord Lieutenant to inquire into the alleged scarcity of milk in certain parts of Ireland; where it exists, its causes, the effects on public health, and the remedies; and also to inquire into the dangers of contamination and infection of the present milk supply and the best means to be adopted to guard against these dangers. The report is divided under two heads:—(1) The milk supply; (2) the purity of the milk supply. The Commission find that in cities and large towns there is no actual scarcity in the supply of milk; that it is not more freely used is due either to ignorance of its value as a food or to poverty. The suggestion is made that where poverty prevents the use of fresh milk separated milk might more frequently be used by adults. One recommendation is made that city and urban authorities should be empowered to contribute from the rates towards the cost of establishing milk depots for infants. Passing from the large to the small towns, the Commission find that while as a rule there is no scarcity of milk in the summer, there is a partial scarcity, more or less accute, during the winter season—*i.e.*, from November to March. To meet this need various remedies are pointed out.

In the rural districts the great problem, however, has been to find remedies for the scarcity of milk in the country, for, paradoxical as it may seem, the scarcity of milk is felt more in rural than in urban districts. From the report it appears that the habits of living amongst the peasantry have during the past 20 years entirely changed—much for the worse; that whereas formerly they lived on milk or buttermilk and oatmeal they now take tea and baker's bread. The disuse of stirabout is also attributed to the lack of milk. The Commission, therefore, dwell on the need of popular instruction as to the value of milk as a food, and suggest ways in which knowledge on the subject could be spread.

Contamination of the Milk Supply.—Under part II., which deals with the prevention of contamination of the milk supply, the report deals at length with the question of eliminating tuberculosis among cattle.

Next in importance to the stamping out of tuberculosis among cattle is the necessity of preventing the use of milk infected with disease. The following recommendations are made: (1) That if the milk of a particular dairy is suspected of causing typhoid or diphtheria, the public health authority of the district in which the outbreak occurs should have the power (a) to take the necessary steps to ascertain if there is a typhoid or diphtheria carrier in the family or employment of the milk-seller, and, pending the result of investigation, to suspend the sale of milk from the dairy; and (b) to go at once without a magistrate's warrant to the farm of the supplier, and require all persons in his employment to give facilities for tests to be made, failing which the authority should have power to forbid the sale of the milk of that supplier within their area.

It is also recommended that the public health authority should have power to stop the sale of milk from any dairy in their district if there is epidemiological evidence that it is the vehicle of infection. A scheme for the establishment of stations for bacteriological examination is set forth, and among other subjects dealt with in the report are the sterilisation and Pasteurisation of milk, the effect of temperature on milk, dried milk, and condensed milk.

MEDICAL NEWS IN BRIEF.

Irish Medical Schools' and Graduates' Association.

THE autumn dinner of this Association was held on Thursday, October 30th, at the Hotel Cecil, Dr. Wm. Douglas, President, in the chair. About 160 ladies and gentlemen sat down to enjoy an excellent repast. Amongst them may be mentioned the Rev. Msgnr. Johnston, Prof. F. G. Donnan, Drs. Michael Taylor, Macnaughten Jones, Douglas Reid, Joyce, A. Prineas Abraham, Lieut.-Col. Moorhead, Surg.-General Greams, Mr. J. Murray (Surgeon to the Middlesex Hospital), Mr. Charles Ryall, Rev. Dr. Houston-Collison, etc. After the usual loyal toasts had been duly honoured, Dr. Shepherd-Boyd proposed "Our Defenders," to which Lieut.-Colonel Moorhead responded. The Arnott Memorial Medal was then presented by the President to Dr. P. P. Garland, C.M.G., for gallantry in Africa—sucking a wound made by a poisoned arrow. Dr. Garland was introduced by Dr. R. Jocelyn Swan. "Our Guests" was proposed by Dr. T. Hobbs Crampton. This toast was responded to by Prof. Donnan in felicitous words and by Monsgnr. Johnston in a speech teeming with anecdote. Next Dr. Macnaughten Jones presented a loving cup, or rather jug, to the Association in memory of having been President three times. The jug was of a very old Irish pattern, and Dr. Macnaughten Jones accompanied the presentation with a few graceful words, which were much appreciated. The health of the President was then proposed by Dr. M. J. Bulger. The toast having duly been honoured, Dr. W. Douglas responded. The musical arrangements were excellent. Besides some pleasant singing by Miss Kitty Ryan and Mr. Lorne Wallet, Dr. Byrne gave a musical sketch and the Rev. Dr. Houston-Collison delighted the audience with Irish songs given in his own inimitable way.

A Fund for Medical Students.

MRS. CAROLINE CONRADINE SOPHIA DICKINSON, of Boscombe, widow of Mr. James Bathgate Dickinson, left estate of the gross value of £15,499, of which the net personalty has been sworn at £13,939. Mrs. Dickinson left £1,000 to endow a "James Bathgate Dickinson" bed in Manchester Royal Infirmary, and £500 to endow a "James Bathgate Dickinson" cot in the Royal Victoria and West Hants Hospital. Subject to several other bequests, she left a fund of £8,180 16s 6d. upon trust to provide four "James Bathgate Dickinson" scholarships for medical students at the Manchester Royal Infirmary and at Owens College, Manchester, one-fifth for a scholarship in anatomy, one-fifth for one in pathology, one-fifth for a research scholarship in surgery, and two-fifths for a research scholarship in medicine. If her estate will then admit of it, she further left £1,800 upon trust, as to one-half for a scholarship in chemistry tenable at the Stalybridge Technical School, and as to one-half upon trust for Epsom College (formerly the Royal Medical Benevolent College) for such purposes other than building as the governors may think fit.

A New Hospital at Tranmere.

The practical completion of the new infirmary and hospital attached to the Tranmere Workhouse was recorded last week, when, at the invitation of Colonel G. F. Allender, the Chairman of the Works Committee, a number of members made an inspection of the building. Accompanied by Colonel Allender, Mr. Edmund Kirby (the architect) and Mr. W. H. Forde (the builder), the guardians toured through the spacious and well-appointed building, which has cost the ratepayers in the Birkenhead union between £56,000 and £60,000.

The Army Medical Service.

The prizes were distributed at the Royal Army Medical College last week by Surgeon-General Sir Havelock Charles. Among those present were Major-General Sir Francis Lloyd (commanding the London District), Surgeon-General. A. W. May (Medical Director-General of the Navy), Surgeon-General Sir James Porter, Surgeon-General Sir Francis Trevor, and the Commandant of the College, Col. B. M. Skinner.

In the course of his address to the officers, Sir Havelock Charles said it was necessary for any man entering upon such a life as theirs to see that his equipment was all that it should be, and also to pay attention to the fact that that equipment should continue up to such a mark as to keep up with the progress of medical science. Referring to the kindred services—the Indian Medical Service and the Royal Army Medical Corps—Sir Havelock said there should be no rivalry. Neither could progress if the other was hurt. To those entering the Indian Medical Service he said there were chances for a man who was still a junior officer. He would be placed in situations where he would have independent charge and be able to show his individuality and personality.

The New King's College Hospital.

The out-patients' department and a portion of the wards of the new King's College Hospital at Denmark Hill will be opened for the reception of patients on Monday, November 10th.

The Royal Institute of Public Health.

The Most Honourable the Marquess of Linlithgow has accepted the Presidency of the Congress of the Royal Institute of Public Health, to be held in Edinburgh from Wednesday, July 8th, to Monday, July 13th, 1914, inclusive, on the invitation of the Right Honourable the Lord Provost and the City Council.

The Royal Army Medical College Awards.

At the recent examination held on the termination of the junior course of instruction at the Royal Army Medical College, Lieutenant R. B. Price was awarded the Parkes Memorial, Tulloch Memorial, and Herbert prizes. The De Chaumont prize was awarded to Lieutenant A. L. Urquhart, and Lieutenant H. C. D. Rankin received the Marshall Webb and second Montefiore prizes.

British Medical Association.

A special representative meeting of the British Medical Association will be held on Thursday, December 4th, and if necessary on the following day, at the Connaught Rooms, Great Queen Street. The business will include the question of increasing the annual subscription to two guineas for members in the British Isles, the report of the State Sickness Insurance Committee, and various matters relating to the Insurance Act.

The Royal College of Physicians of London.

At the ordinary quarterly *comitia* of the Royal College of Physicians, held last week, the President of the College, Sir Thomas Barlow, in the chair, Dr. Frederick Taylor was re-elected a member of the Committee of Management of the Examining Board in England. On the recommendation of this committee the Central London Ophthalmic Hospital was recognised for the course of clinical instruction in ophthalmic surgery.

The following were admitted to the membership:—J. R. Collins, M.D.Dublin; R. R. Elworthy, M.B. Lond., L.R.C.P., and M.R.C.S., Westminster; G. Graham, M.D.Camb.,. L.R.C.P., and M.R.C.S., St. Bartholomew's; J. A. Braxton Hicks, M.D.Lond., Westminster; C. M. Wilson, M.D.Lond., L.R.C.P., and M.R.C.S.

The following had licences to practise physic granted to them at this meeting:—C. S. Archer; W. S. Armitage; C. S. Atkin; F. G. Bell; F. V. Bevan Brown; W. G. Bigger; G. A. Bird; J. Bostock; G. J. Bowen; H. J. Bower; E. J. Bradley; E.H.P. Brunton; N. St. John G. D. Buxton; J. Byrne; E. W. Carrington; F. S. Charnock; Ferozeshah Bapuji Chenoy; F. Cook; G. M. Coope; E. Copians; C. H. Crawshaw; W. Ll. G. Davies; H. V. Deakin; H. S. De Boer; H. R. Dive; A. R. C. Doorley; E. J. Eacrett; A. T. Edwards; Hassan el Arculi; A. S. Erulkar; A. R. Esler; W. S. Evans; J. M. Evatt; B. J. L. Faye; M. Ffoulkes; A. C. Hancock; R. J. Harley-Mason; F. T. Hill; T. A. Hindmarsh; E. W. N. Hobhouse; A. N. Hooper; O. R. Horwood; H. F. Hutchinson: T. H. James; G. B. Jameson; F. E. Johnson; R. B. Johnson; C. Kingston; J. I. F. Knight; N. C. Lake; J. L. Lauder; J. L. D. Lewis; C. C. Ling; W. H. Lister; G. T. Loughborough; O. G. Maginness; D. Mallam; G. N. Martin; E. E Mather; H. Mather; J. Millard; G. H. Monrad-Krohn; J. Y. Moore; W. Morris; J. T. Morrison; M. C. Murphy; M. B. O'Sullivan; H. B. Owens; H. W. Parnis; W. P. Penhale; V. C. Pennell; J. A. Perera; A. S. Plant; J. Precopoulos; E. Rayner; S. J. S. Reid; Evelyn Ritson; C. S. L. Roberts; W. E. R. Saunders; A. E. Schokman; L. E. S. Sharp; G. D. Sherwood; Jagannath Vishnu Shirgaokar; A. C. S. Smith; A. J. E. Smith; H. J. D. Smythe; A. K. Soutar; T. S. Stafford; W. A. Stewart; J. W. Stretton; W. V. T. Styles; W. E. Tanner; J. W. Thomas; J. A. Tsoi-A-Sue; F. C. Turnbull; Chunilal Bhimbhai Vakil; W. H. von Wyss; J. G. Wardrop; C. W. Wheeler-Bennet; C. E. Williams; H. A. Williams; F. E. S. Willis; C. W. Wilson; H. G. Wiltshire; H. G. Winter.

Trinity College, Dublin.

The following candidates have passed the Preliminary Scientific Examination, Michaelmas Term, 1913:—

Physics and Chemistry.— Robert W. Nesbit, Olive G. Blackham, Richard M. B. Gamble, Wilfred V. Pellissier, Frederick J. Smith, William P. Elford, Joseph R. Brennan, Randolph N. C. Murray, Rita Henry, Meta G. Jackson, Stanley C. Mitchell, Harry Banks, Roney Moore Patterson, Richard P. Tobin, Henry J. Rice, Thomas R. H. Dorman, William P. Lubbe, William Andrew Byrn, George Cyril Robb.

Botany and Zoology.—Eric W. S. Deale, Percival A. Dormer, Bryan A. McSwiney, passed on high marks; George F. Fitzgerald, Hirsh Brill, Randolph N. C. Murray, Francis Young Pratt, Thomas S. McDonald, Paul C. Hallowes, James E. T. Nelis, Thomas B. H. Tabuteau, Fleetwood W. P. Sullivan, Walter Martyn Rennison, William Tenison Collins, Crawford L. L. Wilson, Hastings H. Molloy, Norman Gray, Alfred J. Beckett.

Intermediate Medical Examination, Part I.—Sydney V. Furlong, Andries A. L. Albertyn, Grosvenor L. Murphy, William A. N. Oakshott, Robert B. N. Smartt, Charles H. Comerford, Mortimer McG. Russell, John P. Macnamara, Joseph H. C. Walker, George W. Doran.

Intermediate Medical Examination, Part II.—Wm. Hunt, Herbert S. Collins, Violet M. Deale, George O. F. Alley, William E. B. Collins, John Milo Ryan, Henry S. Campion, Francis W. O'Connor, James E. Jameson, Cecil McL. West, William F. Wilson, Henry A. Burridge, Ernest James Hamilton, Thomas E. B. Beatty.

Preliminary Scientific Dental Examination.—Physics and Chemistry.—Maurice Counihan.

NOTICES TO CORRESPONDENTS, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £2 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistancies, Vacancies, Books, etc.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

REPRINTS.—Reprints of articles appearing in this JOURNAL can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

You may talk about poetry, music, and art,
You may talk about conscience and talk about heart,
  You may talk about knowledge, and talk about wit,
  The bane of inspection's the ubiquitous NIT.
(With apologies to Owen Meredith).—*New York Medical Journal.*

MR. A. WELCH (London, E.).—The matter has been taken up seriously by the National Society of Chiropodists, Ltd., 1 Silver Street, Bloomsbury, W.C., who are pledged by their bye-laws not "to operate on the hands or feet for congenital or acquired deformities, or for conditions requiring the use of anæsthetics other than local, or incisions involving the structures below the level of the true skin." The observance of true asepsis is also laid down as a principle to be most strictly observed.

THE CHADWICK PUBLIC LECTURES.

THE two remaining lectures on "The Place of the Open-Air School in Preventive Medicine," will be delivered under the Chadwick Benefaction, by Sir George Newman, M.D., Chief Medical Officer of the Board of Education, at the University of London, South Kensington, S.W., on Tuesdays, November 11th and 18th, 1913, at 5 p.m. Sir Alfred Pearce Gould, M.S., K.C.V.O., Dean of the Faculty of Medicine, will take the chair. Admission free, without ticket.

F.R.C.S.EDIN. (Reading).—The only true test of the lack of sugar in the diet of an infant is the character of the weight chart, which rises and falls irregularly, the temperature also being irregular and generally subnormal. The condition is described by Finkelstein as that of "weight disturbance."

M.B. (Sussex).—The condition is certainly one in which medical aid should have been sought from the beginning. No midwife has any right to let an eruption go on in an infant without skilled treatment. Cases of true pemphigus neonatorum are frequently streptococcal in origin.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, NOVEMBER 5TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF OPHTHALMOLOGY) (1 Wimpole Street, W.).—8 p.m.: Cases by Mr. Sydney Stephenson, Mr. George Coats, Mr. J. L. Birley, Mr. Charles Killick, Mr. A. S. Cobbledick. 8.30 p.m.: Papers: Mr. George Coats: Some Instances of Disease in the Animal Eye. Mr. C. Wray: Obstruction of Lacrymal Duct and its Treatment.

THURSDAY, NOVEMBER 6TH.

ROYAL SOCIETY (Burlington House, London, W.).—Mr. A. D. Hall, Mr. W. E. Brenchley, Mr. L. M. Underwood, Prof. E. W. MacBride, Prof. B. Moore, Mr. T. A. Webster, Dr. B. Blacklock, Dr. W. Yorke, Mr. T. G. Brown, and Mr. J. O. W. Barratt.

ROYAL SOCIETY OF MEDICINE (SECTION OF OBSTETRICS AND GYNÆCOLOGY) (1 Wimpole Street, W.).—8 p.m.: Discussion: On the Relation of the Internal Secretions to the Female Characteristics and Functions in Health and Disease (opened by Dr. W. Blair Bell, followed by Miss Louise McIlroy).

NORTH-EAST LONDON CLINICAL SOCIETY (Prince of Wales's Hospital, Tottenham, N.).—4.15 p.m.: Clinical Meeting.

FRIDAY, NOVEMBER 7TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF LARYNGOLOGY) (1 Wimpole Street, W.).—4 p.m.: Cases and Specimens by Mr. Herbert Tilley, Dr. Watson Williams, Dr. Dan McKenzie, Mr. T. Guthrie, Mr. Mollison and Mr. Turner, Dr. Donelan, and others.

ROYAL SOCIETY OF MEDICINE (SECTION OF ANÆSTHETICS) (1 Wimpole Street, W.).—8.30 p.m.: Cases by Mr. Fleming, Mr. J. H. Chaldecott, Mr. C. W. G. Bryan, and Mr. Apperly.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammersmith Road, W.).—8 p.m.: Special Clinical Evening. Cases will be shown from 8 p.m. to 8.30 p.m.

MONDAY, NOVEMBER 10TH.

MEDICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—8.30 p.m.: Discussion on "The Treatment of Neurasthenia," introduced by Dr. Risien Russell, to be followed by Sir Victor Horsley, Dr. James Taylor, Dr. Grainger Stewart, Mr. Donald Armour, Dr. T. B. Hyslop, Dr. Leonard Guthrie, Dr. T. J. Horder, Dr. M. B. Wright, Dr. A. G. Buchanon, and Dr. Claud Fothergill.

TUESDAY, NOVEMBER 11TH.

ROYAL SOCIETY OF MEDICINE (SECTION OF SURGERY).—5.30 p.m.: Adjourned Discussion on Mr. Frank Kidd's Paper on "Pyeloradiography." The following will take part in the discussion:—Mr. Gilbert Scott, Mr. Thomson Walker, Mr. John Pardoe, Mr. Ralph Thompson, Mr. A. E. Johnson, and others.

Appointments.

BLAIR, MARY A., M.D., B.S.Lond., Clinical Assistant in the Gynæcological Department at the Royal Free Hospital.

CLARKE, H., M.B., B.S., Junior Obstetric Assistant at the Royal Free Hospital.

DEARNLEY, GERTRUDE, M.B., B.S.Lond., House Physician at the Royal Free Hospital.

HUNTER, JAMES, M.B., Ch.B.Aberd., Medical Officer and Public Vaccinator for the Parish of Forgue, Aberdeenshire.

LEACH, R. E. H., M.B., B.S.Oxon., Certifying Surgeon under the Factory and Workshop Acts, for the Bungay District of the County of Suffolk.

PICKARD, ELLEN M., M.D.Lond., Medical Registrar at the Royal Free Hospital.

Vacancies.

Certifying Factory Surgeon.—The Chief Inspector of Factories announces the following vacant appointment:—Stoney Stanton (Leicester).

Certifying Factory Surgeons.—The Chief Inspector of Factories announces the following vacant appointments:—Abersychan (Monmouthshire), Lochgilphead (Argyllshire), Peterborough (Northants). Sedgeley (Staffordshire), Tarbert (Argyllshire), Whaley Bridge (Cheshire).

Kent County Asylum, Maidstone.—Fourth Assistant Medical Officer. Salary £200 per annum, with furnished quarters, attendance, coals, gas, garden produce, milk, and washing Applications to the Medical Superintendent, Asylum, Maidstone.

The Hospital for Sick Children, Great Ormond Street, W.C.—Surgeon to Out-Patients. Applications to the Secretary. (See advt.).

Scalebor Park Asylum, Burley-in-Wharfedale.—Assistant Medical Officer. Salary £200 per annum, with board, furnished apartments, attendance, etc. Applications to the Medical Superintendent.

Herefordshire General Hospital.—House Surgeon. Salary £150 per annum, with board, residence, and washing. Applications to W. A. W. Price, F.C.I.S., Secretary.

Births.

BENSON.—On October 28th, the wife of J. R. Benson, F.R.C.S., Circus House, Bath, of a daughter.

BROMLEY.—On October 31st, at Sible Hedingham, Essex, the wife of Dr. James Bromley, of a daughter.

DICK.—On October 28th, at "Rossendale," Cazenove Road, Stamford Hill, N., the wife of J. Lawson Dick, M.D., F.R.C.S., of a daughter.

HENDERSON—On October 29th, at 48 Rodney Street, Liverpool, the wife of Dr. W. Savile Henderson, of a son.

LIGHTSTONE.—On October 28th, at 12 Fairfax Road, N.W., to Dr. and Mrs. H. Lightstone—a daughter.

LONGLEY.—On November 1st, at Strathearne, Saltburn-by-the-Sea, the wife of J. Alan Longley, F.R.C.S.E., of a son.

MALINS.—On October 26th, at 3 Avon Place, Warwick, the wife of Dr. Herbert Malins, of a daughter.

ROOKE.—On October 26th, at "Fairfield," North Finchley, N., the wife of William Stanley Rooke, M.R.C.S., L.R.C.P., of a daughter.

SIMMONS.—On October 28th, at 2 Southwick Place, Hyde Park, the wife of Dr. G. Alan Simmons, of a son.

WARD.—On October 29th, at Southfield, Yarm Road, Stockton-on-Tees, to Dr. and Mrs. Ward—a son.

Marriages.

MERCIER—MACDOUGALL.—On October 29th, at St. Pancras Church, London, Charles Arthur Mercier, M.D., F.R.C.P., F.R.C.S., of Parkstone, Dorset, to Mary MacDougall, youngest daughter of the late Donald MacDougall, of Glasgow.

Deaths.

GODSON.—On October 26th, at Cheadle House, Cheadle, Cheshire, Alfred Godson, M.B., J.P., aged 77 years.

MALINS.—On October 28th, at 3 Avon Place, Warwick, Mary, daughter of Dr. and Mrs. Herbert Malins, aged 2 days.

NETTLESHIP.—On October 30th, at Longdown Hollow, Hindhead, Edward Nettleship, F.R.S., F.R.C.S., aged 68.

ORAM.—On October 1st, at sea, Louisa, wife of Dr. Percy Sprague Oram, daughter of the late Lewis and Louisa Sharp, of Comer Gardens, Worcester, and Cazenove Road, Stamford Hill, N.

PARSONS.—On October 29th, at Oakhyrst, 4 Park Hill Rise, Croydon, Henry Franklin Parsons, M.D., F.G.S., late of the Medical Department, Local Government Board, aged 67 years.

TURTLE.—On October 30th, at "Kirkmead," Woodford, Essex, from pneumonia, Marion, eldest daughter of Frederick Turtle, M.D.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX"

VOL. CXLVII. WEDNESDAY, NOVEMBER 12, 1913. NO. 20.

NOTES AND COMMENTS.

An Unqualified Practitioner with a Title.

THE limit of amateur doctoring appears to have been reached by Lord Sandwich. According to his own account, he has enjoyed, and still enjoys, an enormous practice among credulous folk in all classes of society. He states specifically that there are few serious maladies to which his healing powers have been unsuccessfully applied. His public profession was made—can it be believed?—within the classic walls of University College, London, at a meeting held to mark the opening of a medico-psychological clinic for the treatment of diseases by means of phychotherapy. His Lordship, after first remarking that the mind had an immense power over the body, stated that while he did not pretend to medical or surgical knowledge, he nevertheless had great experience in healing. After the South African war, he had some 60 wounded officers at his country house, and there was never a nurse or a doctor in the house. He had attended people in palaces, in cottages, in hospitals, in homes, and his patients included a Hindu monk in his monastery, a Mahomedan in his mosque, and so on. He had been asked to explain his power, but he had nothing to explain; he only knew what happened. If he were possessed of that power, there must be many others possessed of lesser powers of healing. So there are, scores of hundreds of persons who lay claim to a supernatural power of healing. One of the most notorious of these pretenders was Mrs. Eddy, who gathered untold riches from her beliefs and practices. Lord Sandwich is an amiable English peer of transparent honesty, but his candour does not prevent a ridiculous assumption of powers that are fraught with constant tragedies.

Sandwich and Sandow.

CAN Lord Sandwich cure a broken leg, or replace a disorganised liver or kidney? If one of the sick folk under his care happen to have a specific complaint, can he still bring about a cure by his "power of healing"? If he can cure one malady, he ought to be able to cure all maladies, for, apparently, he placed no limit on his powers. It would be interesting to learn fuller details as to the 60 "wounded" officers that he so hospitably harboured after the Boer war. What was the precise nature of their wounds? What surgical treatment had been previously administered? What was their subsequent history? It is, of course, obvious that many minor ailments cure themselves, and many aches and pains and mental moods yield to Nature's remedies, such as sleep, fresh air, food, rest, regular habits, good surroundings, and so on. Doubtless persons suffering from such trivialities have furnished the greater part of the vaunted triumphs of Lord Sandwich. All practice of the kind is fraught with the gravest danger, inasmuch as it may lead to the neglect of early or of hidden disease of a serious kind, to tamper with which may raise the issue between life and death. The announcement of such claims as these from an acknowledged seat of learning renders the matter doubly dangerous. The man in the street is ever ready to lend his ear to the wiles of unqualified medical practice. One of the best illustrations of the kind is the claim of Sandow to remedy and cure all sorts of human maladies, a practice which has been shown in these columns to have been carried on under the Royal Arms of H.M. King George.

"Enlightened and Intelligent."

THE jury at an inquest at Waltham Cross found that death was due to heart failure, and added the following rider: "We are of opinion that the three doctors called in were guilty of most inhuman conduct in not attending, and we wish especially to censure Dr. Best for demanding his fee before attending what was evidently an urgent case." We do not, as a rule, look for any high order of intelligence in a coroner's jury—no one but an attorney even pretends to—but we do expect a certain amount of ordinary justice. This egregious rider shows an amazing state of things. Previous to the Insurance Act medical men were graciously permitted to distribute a great deal of vicarious charity at their own expense. They cast bread upon the waters uncomplainingly, and it came back to them in the rare and refreshing fruits of the panel system. And now an appalling thing has happened. Medical men will not work for nothing, and the law and order of the nation stand aghast at such unprecedented effrontery. Dr. Best asked for payment. Whoever heard of such a thing? It was two o'clock in the morning and he had a bad cold, but what of that? The pampered panel doctors of a servile State must not stay upon such trifles. It is their lordly privilege to dash out at the call of every hysterical alarmist who would not insult them by proffering a fee. And if they take their hard-earned rest and make the least show of asserting what is an obvious right for the rest of the world—fancy if a grocer was censured for refusing a free supply of bread to a starving man—the awful penalty of a jury's frown awaits them. A document so foolish is its own rebuke, and we venture to think that the three gentlemen concerned will survive the empty thunderings of the officious casuals who filled the jury box on this memorable occasion.

The Situation at Wisbech.

A SPECIAL meeting of the Isle of Ely Insurance Committee was held at March last week, at which the situation in Wisbech, in regard to the administration of medical benefits under the Insurance Act, arising out of the death of Dr. Dimock, was discussed. A resolution was adopted unanimously expressive of sympathy with Dr Dimock's family, and also recording the appreciation of the Committe of the manner in which he had discharged his duties. It was the wiser plan, under the circumstances, to decide upon the appointment of an outside practitioner to fill the vacancy thus created upon the panel, rather than incur the risk of arousing further local feeling by opening the panel to medical men resident in Wisbech. No good can possibly accrue from speculating upon the manner in which the alleged "persecution" of the deceased practitioner, if, indeed, any existed at all, was carried out, since it is announced that the Home Office has been asked by the Insurance Act Committee, acting on behalf of the British Medical Association, to hold an inquiry into all the facts of the case. Those medical men against whom hostile demonstrations were recently made are certainly in a somewhat unpleasant position, but it is satisfactory to note that, at the meeting referred to, a resolution of "continued confidence in the honour" of one of the most prominent of their number, was passed unanimously. Meanwhile the public, as well as the local members of the profession, will do well to refrain from further criticism until the inquiry has been instituted and its results made known.

A City without Flies.

Bohemia is blest, according to an American Consular report, by an almost complete absence of flies. The reason appears to be in the thoroughness of the sanitary administration, whereby decaying animal or vegetable refuse is not permitted to accumulate or to remain uncovered in or near dwellings. There does not appear to be anything favourable to flies in the air of Bohemia. The Consul at Prague reported recently to his home authorities in America that it was no use attempting to establish a trade in flypapers in that city, because there were so few flies about. Here in the United Kingdom it is to be feared that the Consular report would have of the restaurants, whether in the drab East or the pointed in the opposite direction for a visit to any gilded West, would reveal dining-rooms and kitchens swarming with flies all the year round. If the London County Council wishes to do a piece of real, sound, practical work in public health it has merely to insist that all restaurant keepers shall rid their establishment of flies. This can be effected by the use of suitable fly-traps, poisons and screens, but, above all, by freeing the neighbourhood of refuse and rubbish. Under present conditions there can be little doubt that a great deal of preventable sickness is distributed by the restaurants and other places where food is sold in the Metropolis.

LEADING ARTICLES.

THE BRITISH MEDICAL ASSOCIATION.

As our great medical organisation, the British Medical Association has a claim on the forbearance of every member of our profession. At the same time it would be simple weakness to ignore defects and failings that may end in disaster. The career of the Association during the past few years has been chequered. It put up a good fight against the National Insurance Act legislation and—as must be admitted by friend and foe—it secured substantial concessions from the Government. The confidence of members was first seriously shaken by the acceptance of a high official post among the Insurance Commissioners by their then Medical Secretary. The Council adopted policies that it had not strength to maintain, notably in the shape of the pledge. It delayed its final strategy until several weeks after the Act came into operation, with the result that the main body of the profession fled helter-skelter to the panels. The Council has since reversed its original attitude and become pro-panel. Hesitancy and inconsistency of this kind were not altogether surprising in so grave a crisis, but they had the inevitable effect of causing a good many resignations from the Association. Nor have matters been mended by subsequent events. The recent Bedford libel case showed that absolute injustice could be meted out to a brother medical man by a Branch Association. Now come the final proposals of the Council to extract more money from members. On Thursday, December 4th, a special representative meeting will be held in London to deal with certain resolutions adopted by the annual representative meeting at Brighton in July last. The first important matter to be thus considered is the proposal to raise the subscription from twenty-five shillings to two guineas. Some years ago the subscription was raised from one guinea to twenty-five shillings, and we cannot help regarding the contemplated further increase with apprehension. Should it be carried into effect it seems not altogether unlikely that a temporary check to the advance of the Association may be turned into a disastrous rout. At the same time it is proposed to invite subscriptions from members in order to organise the profession more thoroughly. The appetite for more money, indeed, seems to have degenerated into an insatiable craving, for it is intimated in the *B.M.J. Supplement* for November 1st that advantage will be taken of the special meeting to hold the necessary special meetings required to extend the memorandum of the present company so as to include the power of borrowing money on mortgage or otherwise. This innocent-looking proposal demands careful consideration of members. It may be, of course, that the financial condition of the Association is so desperate that its existence can be prolonged only by the spendthrift resource of living on loans. In any case, as pointed out previously in these columns, the wise and prudent course would be in the first place to cut down expenditure. The *Journal* is a magnificent property which under expert journal management should yield an income almost if not altogether sufficient in itself to satisfy the reasonable needs of the Association. It would be well to conduct a stringent examination into the costs of production of the *Journal*, and if this prove unsatisfactory in comparison with other journals, to lease the publication to outside firms. At this precise moment, moreover, it has come to our knowledge that the management has substantially raised the price of advertisements, already heavy. It may be said that this is a purely office affair, but, on the other hand, it does not lessen the impression of financial stress caused by the proposal to raise subscriptions and to borrow money. The central defect in the Association, if plain speaking be permitted, is its tendency to drift into the control of a small central clique. Years ago the same thing existed and the governing knot of members was known as the "Vital Centre." The constitution of the Association was reorganised not long ago in the hope that control would pass into the hands of members. Recent events, however, have not tended to the belief that the broadening policy has been a success. It would be an irreparable loss to the medical profession of the United Kingdom if the Association were to break down after so many years of steady and fruitful enterprise, but so far as can be gathered from surrounding signs and portents, that body stands in earnest need at the present moment of wise and prudent counsels and of sagacious leadership and disinterested service. As to the financial aspect of the case, the Executive proposes to upset a constitution in order to find new methods of raising income; and it is obviously within the right of every member of the Association to demand that the reasons for the failure of the present system be demonstrated by independent expert authority.

CURRENT TOPICS.

A Committee on Anthrax.

The recent fatalities from anthrax, especially the last case in which salvarsan was used as a remedy, have brought that disease prominently before the public. Comparatively little anthrax is seen in London, a few isolated cases being met with sometimes at Guy's Hospital from the tanneries situated in the district of Bermondsey. The majority of the cases occur in Bradford, the principal seat of the wool-carding and sorting industry. With a view of minimising the risks attendant upon the workers in this trade, the Home Secretary has appointed a Committee to inquire into the dangers from infection by anthrax in the processes of sorting, willeying, washing, combing, and carding wool, goat-hair, and camel-hair, and in the processes incidental thereto; and to consider and report whether any, and if so what, amendments are desirable in the regulations for these processes made under section 79 of the Factory and Workshop Act, 1901. The members of the Committee are:—The Right Hon. Sir Thomas P. Whittaker, M.P. (Chairman); Mr. W. Barber, secretary to the Bradford Trades and Labour Council; Dr. F. W. Eurich, M.D.; Alderman J. E. Fawcett, President of the Bradford Chamber of Commerce and Chairman of the Anthrax Investigation Board; Colonel E. H. Foster; Mr. T. Grundy, secretary to the National Union of Woolsorters; Dr. T. M. Legge, M.D., one of His Majesty's Medical Inspectors of Factories; Mr. Ernest Marsh; and Mr. S. Parker, secretary to the Bradford and District Wool Top and Noil Warehousemen's Union. The Secretary to the Committee is Mr. G. E. Dickering, one of His Majesty's Inspectors of Factories, and any communications on the subject of the inquiry may be addressed to him at 72, Bridge Street, Manchester. The inclusion of Dr. Friedrich Wilhelm Eurich, Professor of Forensic Medicine at Leeds University, will be welcomed by the medical profession, as he has devoted special attention to anthrax. Dr. Eurich is Bacteriologist to the Bradford Anthrax Investigation Board, and Specialist Medical Referee to the Home Office for anthrax and for aniline poisoning, and he holds important hospital appointments at Bradford.

Astrology in Medicine.

Of all the different sciences that claim, in however distant a manner, to possess any bearing upon medicine, that of astrology may be said to have received the least attention. In an enlightened and practical age like the present, it is hardly credible that scientific observers could take seriously the suggestion that medicine could derive any help or inspiration from a science which is now as extinct as the dodo. Nevertheless, from the historical aspect, many interesting facts may be culled from the study of a science which flourished in Chaldea in 1800 B.C. In the first of a series of Fitz-Patrick Lectures on "Astrology in Medicine," delivered last week at the Royal College of Physicians of London by Dr. C. A. Mercier, it was stated that astrology had formed an important part of the life of every nation which had advanced beyond barbarism. The casting and reading of horoscopes, and the attempt to prognosticate disease according to the degree of ascendancy of a particular planet, are still indulged in at the present day by thoroughly up-to-date individuals, who number among their clients all classes of people, some of them highly intellectual, who revel in things mystical. A universal system of medicine was even propounded by Bacon, and people are still described as having been "born under a lucky star," or who are saturnine, jovial, or mercurial. With regard to medical astrology, much curious information has been unearthed by Dr. Mercier, which will form a valuable contribution to the study of the history of medicine, even though it may not have any practical bearing upon the diagnosis or treatment of disease.

The Recognition of Hysteria.

Despite the numerous theories that have been advanced from time to time to account for the sundry and manifold phenomena of hysteria, it cannot be said that the last word has yet been said with regard to the ætiology of this disease. As protean in its aspects as syphilis, it frequently baffles all attempts at diagnosis and treatment. Some interesting points were raised the other day by Dr. T. R. Glynn, Professor of Medicine in the University of Liverpool, in his Bradshaw Lecture delivered at the Royal College of Physicians of London on "Hysteria in Some of its Aspects." Dr. Glynn supported the views of Sir James Paget, Dr. Savill, and others, with regard to the dependence of the majority of hysterical phenomena upon neuro-vascular instability. It seems pretty clear that, of all the different sensory, visual, and psychical stigmata of hysteria, the only unequivocal sign of the disease is the presence of the so-called hysterogenic zones. The presence of a little analgesia upon the back of one fore-arm, or upon the side of the forehead, is sometimes a valuable indication of the hysterical nature of an obscure nervous condition. In many instances no very obvious signs of the affection are present, and these cases are the most difficult to diagnose. Should some organic disease be present at the same time, matters are apt to be somewhat complicated. Of the motor manifestations of hysteria the rhythmic tremors and spasms may be regarded as being the most typical of the disease. Considerable care must be taken to avoid the assumption that all persons of an hysterical nature, or suffering from actual hysteria, are necessarily deceitful. It is true that the mental stigmata of degeneracy are frequently found associated with true hysteria, but it should always be borne in mind that the hysterical individual needs to be treated as a whole, both the mental and the bodily manifestations receiving equal attention.

The Value of Open-Air Schools.

A FEW years ago the promoters of open-air schools were held to be faddists devoid of the true educational spirit. As long as class-rooms were adequately ventilated, it was agreed that anything further was superfluous. With the growth of the anti-tuberculosis movement a definite change has taken place in the minds of educational authorities, and, with such an excellent object lesson as Sheffield, the open-air school process has not only come to stay, but is gradually becoming more and more recognised as indispensable. As Sir George Newman, chief medical officer of the Board of Education, stated last week in the first of a series of three lectures on "The Place of the Open-air School in Preventive Medicine," the tide of physical and mental defect in the childhood of the nation is best stemmed by proceeding along the lines of the open-air school. In order to appreciate its value, however, a much larger conception of its aims and objects must be adopted by the scholastic profession. The true basis of preventive medicine cannot be understood until the great problem of infantile mortality is grasped. It has been shown that the three great causes of death between the ages of five and fifteen are tuberculosis, heart-disease, and pneumonia. The larger proportion of the diseases from which school children suffer are capable of being remedied while they are already at school. Increased facilities for medical inspection and, if necessary, for treatment as well will do much to nip disease in the bud, and also to prevent its dangerous sequelæ by supplying an opportunity for repair and by nurturing the backward and debilitated child. A new way of life is thus opening out for children, and it seems likely that a wisely-conducted open-air school will be as effective in promoting health as a convalescent home.

The Early Diagnosis of Cancer.

THE fact that malignant disease in its earliest stages is nearly always amenable to treatment, surgical or otherwise, cannot be too widely known. It is lamentable to think how many valuable lives are sacrificed annually to procrastination on the part of the patient in seeking skilled medical advice. Even medical practitioners are not altogether without blame in allowing their natural caution in expressing a definite opinion regarding the nature of a growth to develop insensibly into a dangerous "wait and see" policy. The records of the surgical and gynæcological out-patient departments at our large hospitals show many instances of the perils incurred in leaving doubtfully malignant conditions too long. In the case of uterine cancer the question of early diagnosis is, of course, of supreme importance from the operative standpoint. As a matter of fact few women are aware of the significance of certain symptoms of the disease which ought to lead them at once to consult a medical man. A good move has recently been made by the Health Committee of the Portsmouth Town Council, who, in conjunction with the Medical Officer of Health, have taken definite steps towards circulating information respecting the early signs of cancer and have made provision for the free microscopical examination of material in connection with cancer. With a view of securing earlier treatment for sufferers from this disease, a public address is to be delivered by a prominent medical man before an audience of nurses and other ladies interested in social and philanthropic movements. Such an example might well be copied by all health authorities up and down the country, for cancer is a scourge second only to tuberculosis in its mortality. Portsmouth may be congratulated in taking the lead in benefiting a large section of the community in this special direction.

Sex Hygiene.

THERE is a lot of talk going on at present about "sex hygiene." Why this title was chosen we do not know. The subject, as discussed, has to do with the advisability of having an organised system of instruction on the physiology of reproduction, and with the best way of presenting such a system to the mind of the average child. Theoretically, such instruction would be extremely beneficial, and it would save the nation a good deal of loss through preventable disease and other such causes. The difficulties of practice are great. The varying precocity of children, the possibility of directing attention to functions not ready for acknowledgment and the immense importance of a suitable personality in the instructor stand colossal in the path. There is no doubt that the thought of sex is becoming cleaner. There is less furtiveness about the consideration of the way of a man with a maid than there has been for ages. A woman may admit that she knows what we all know she knows, and not lose caste thereby. It is part of our period of paganism. Some of us are getting back the Attic appreciation of the splendour of the body. Stark sex is about us, and from being furtively unclean and most undesirably desirable is gaining a clear and joyous assumption of shining nakedness. This general tone, which is beginning to gleam alike through our literature and lives, may make the limping analogies of the schoolroom superfluous. If a child were not smothered in sex suppression he would learn without deliberate instruction. There is no need to tear down a non-existent veil. Here a little and there a little the spongy infant mind would absorb the truth as he does now, but not the shame of sexual secrecy. Then we would need no coarse official tabulation of the tenderest things of life.

Nastin in the Treatment of Leprosy.

THE cure of leprosy constitutes one of the many hopes and inspirations of scientific medicine, and signs are not wanting meanwhile that the day of realisation may be at hand in a somewhat near future. The treatment by nastin, a kind of vaccine derived from pure cultures of the specific pathogenic organism of the disease, have on the whole proved hitherto disappointing. A somewhat different aspect, however, has been thrown upon the matter by a recent report issued by Captain L. Bodley Scott, of the Indian Medical Service. He deals with an extensive experience of nastin during the past 3½ years in the Sylkit Leper Asylum in India. He remarks that while reports of the use of nastin in Europe vary, those from the Far East, Australia, Africa and British Guiana are all unfavourable. He suggests that this variability in result may be due to the fact that the drug is prepared from specifically different strains of leprosy, and that the road to uniform success may lie in the preparation of the vaccine from local leprosy. Captain Scott arrives at the important conclusion that, although no method has yet been discovered of eradicating the lepra bacillus, yet that we have in nastin a means of restoring to lepers health, strength and working power, "with loss of all troublesome or crippling symptoms." He claims that if the results constitute "cure," then all the cases referred to in his report were cured.

Bristol University.

For the last twelve months or more Bristol University has been suffering from a kind of fame which is the last that should be sought by a young university. Early in its career it burdened itself with a load of honorary graduates, mostly persons of no distinction except that they were inhabitants of Bristol who were members of the Council of the University. The status of the honorary degree of a British University will no longer be admitted as commanding respect until its source be known. The criticism which these honorary degrees evoked might have warned the University authorities to be more circumspect in their activities, but it has not had that effect. It appears that certain of the professors have been removed from office without any cause being shown. The worst case is that of Mr. R. P. Cowl, the Professor of English Literature. Mr. Cowl is stated by those who know him to be a scholar of repute and a teacher of ability. He was, in the first place, compelled to exchange his teaching post for a research chair, and, after a limited period as research professor, was dismissed. No cause has been stated, and all demands for a re-consideration of his case have been resisted. A memorandum, signed by some hundreds of professors in the Kingdom, was recently presented to the Chancellor of the University, Lord Haldane, asking him to undertake a personal inquiry, but this also has had no effect. It is quite obvious that unless university teachers are guaranteed a fair security of tenure in their posts, the intellectual calibre of those seeking to be professors will deteriorate. Bristol University has struck a blow at the standard of university teaching as well as of university degrees.

Blindness in Tabes.

The occurrence of optic atrophy, and consequent loss of vision, in the course of locomotor ataxy has been observed by neurologists ever since tabes was first recognised. The question of the relation between the ocular symptoms and the incoordination of movement has been a favourite theme for discussion, mainly on account of the fact that the former may precede or follow the latter. In an interesting paper by Dr. W. J. M. A. Maloney in the *Journal of Nervous and Mental Disease*, it is stated that neither the occurrence of blindness nor of optic atrophy retards or influences the evolution of the structural changes accompanying the tabetic processes in the spinal cord and elsewhere. A certain amount of improvement in the ataxia may result from loss of vision, because the less the attention is monopolised by vision the less the distraction, and the more perfect is the discrimination of sensations from other spheres. There are other cases, however, in which blindness occurs and the ataxia persists or even increases. In the latter case this generally means a rapid advance in the tabetic spinal lesions. Dr. Maloney formulates the law of the relation of loss of vision to tabes thus; "*cæteris paribus*, of two tabetics, at any stage of the disease, one blind, the other seeing, the blind has the greater tendency to persist coordinate, the lesser tendency to become ataxic." The author has adapted this principle to the treatment of tabes by applying a method of enhancing sensory perception known to the blind, and he has found a degree of improvement greater than that obtained by Fraenkel's exercises. An account of his method is to be published later.

PERSONAL.

Dr. Harold Cairns Terry, M.B., Ch.B.Birm., has been appointed Assistant Physician to the Gloucestershire Royal Infirmary.

Dr. John Hern, M.D.Edin., F.R.C.S.Edin., M.R.C.S., has been appointed in Charge of the Ear, Nose, and Throat Department at Darlington Hospital.

Dr. H. E. Corbin, Medical Officer of Health for Stockport, has been appointed Medical Officer of Health for the city of Calcutta at a salary of £1,600 per annum.

Mr. W. L. M. Goldie, F.R.C.S., D.P.H., Assistant Medical Officer of Health for Norwich, has been further appointed to the post of Tuberculosis Officer for that city.

It is announced that Sir Rickman Godlee, P.R.C.S., now on a visit to the United States and Canada, has received the Honorary Degree of LL.D. in the University of Toronto.

Mr. T. W. Letchworth, M.B., B.C.Cantab., F.R.C.S.Eng., has been appointed Ophthalmic Surgeon to Out-patients at the Hampstead and North-West London Hospital.

Professor Charles Richet, of Paris University, has been awarded the Nobel prize for medicine by the Karolinska Institute at Stockholm, for his work on anaphylaxis. This year the prize amounts to the sum of about £7,948.

A memorial to the late Dr. Stanley Bean Atkinson, for many years a member of the Stepney Borough Council, in the shape of a clock tower, erected in Burdett Road, Mile End, was formally taken over by the Council on the 3rd inst.

Dr. Charles Scott Sherrington, M.A., M.D., F.R.S., D.Sc., Holt Professor of Physiology in the University of Liverpool, has been elected to the Waynflete Professorship of Physiology in the University of Oxford, vacant by the death of Dr. Francis Gotch.

The General Medical Council will hold its next session on Tuesday, November 25th. The President, Sir Donald MacAlister, will not be able to attend, owing to his illness, but we are glad to announce that he is progressing favourably. A chairman will therefore be elected for the occasion.

A movement is on foot at Cheltenham College to establish a memorial to the late Dr. Edward Adrian Wilson, who shared the labours and the fate of Captain Scott on his expedition to the South Pole. Subscriptions will be received by the Rev. P. W. Unwin, the College, Cheltenham, or by Mr. John A. Pruen, Merrow, Guildford, Hon. Secretary of the Cheltonian Society.

Colonel Andrew Clark, D.Sc., F.R.C.S., L.S.A., of Folkestone, late of Harley Street, Hon. Surgeon to the King, Consulting Surgeon to the Middlesex Hospital, a Vice-President of the British Medical Association, and a Colonel in the Territorial Medical Service, left estate of the gross value of £21,320, of which the net personalty has been sworn at £17,407.

CLINICAL LECTURE

ON

CHRONIC INTESTINAL STASIS. (*a*)

By Sir ARBUTHNOT LANE, Bart., M.S.Lond., F.R.C.S.,

Senior Surgeon to Guy's Hospital and to the Hospital for Sick Children.

Sir Arbuthnot Lane commenced by expressing his appreciation of the honour of being asked to speak to members of the profession on a subject which was very near and dear to his heart. There were times in one's life, and the present occasion was one of them, when one wished for eloquence, so as to present one's views more impressively and clearly than he felt able to do. But he would do his best, and he had decided to talk, rather than read the paper which he had prepared for the occasion. The subject was chronic intestinal stasis.

Until a little time ago, the subject was one which received ridicule and derision, especially from the medical side. It was considered that there was no such condition as chronic intestinal stasis; and to speak of it argued a prolific and more or less exalted imagination. But the time had now arrived when medical friends had absorbed the term chronic intestinal stasis, and they now read papers about it. He now felt convinced that it was only a question of time before they would arrive at the conclusions that he himself had reached. It was always the way of our profession. It had been so in connection with fractures; they abused and openly stated it to be a criminal procedure and did not hesitate to employ any means, however unjustifiable, to oppose its introduction. The Commission recently appointed by the British Medical Association showed that every word he had said was accurate in every detail, and at the present time everybody knew it was the proper treatment for fractures. Many, of course, lacked the skill needed to carry the treatment out, but he did not doubt that that would improve. Failures were the best experiences one could have; they taught lessons in a way nothing else could.

By chronic intestinal stasis he meant such a delay of the contents of the whole or part of the gastro-intestinal tract as resulted in the absorption of a quantity of toxins or poisons greater than the liver could translate into harmless material, and greater than the kidneys and skin could get rid of. Anyone who had that condition was in serious danger. Unfortunately, from time immemorial, this subject had been in the hands of physicians, who up to the present had not shown themselves capable of handling it; they considered they had a monopoly of the gastro-intestinal tract, whereas they realised very little about it. They called the symptoms "indigestion." If a man had a defective drain in his house, and the pan of his water-closet was getting full, was it likely he would take a test-meal out of that pan, to see whether it reacted to litmus paper, and if it was acid, put in a little bi-carbonate of soda, and if it were alkaline, put in some hydrochloric acid? It would never occur to a doctor to do that. If the householder knew enough about it, a search would be made for the cause of that obstruction; and if the person concerned did not know enough about it he would get someone in who did. The attitude of the physician had been that of dealing with the full pan; he called it "indigestion" and treated it with drugs; but the time for treating these conditions with drugs had passed for ever. The doctor had got to deal with the causes of things, and deal with them in a rational manner. The creed and the superstitions of medicine had got to go too; it was necessary to get to the ground-floor and ascertain the causes of these conditions, when he hoped they would be dealt with effectively.

With regard to the causation of chronic intestinal stasis, that was brought about, in the first instance, by the bad feeding of infants; they were either too frequently fed, or the foods given them were unsuitable, so that there was a delay in their cesspool or big bowel. That resulted in time in definite changes. The ends and the middle of the distended bowel tried to get into the pelvis, which was already occupied by its proper inhabitants—namely, the bladder, the uterus, and the rectum, which all resented the entry of the cæcum, the iliac colon, and the transverse colon. After the bad feeding in infancy there was the maintaining of the erect posture from morning to night. Nature never intended us to occupy the erect posture; we were intended to live as savages, lying about on the ground and sitting on the floor, instead of being erect all our waking hours. There was a general tendency for the descent of the intestines into the pelvis. For a time the muscles were able to control and maintain the intestines in the usual place, but, when they tired, down came the intestines, and an extraordinary delay in the bowel resulted. In the case of the iliac colon dropping into the pelvis, Nature found it inconvenient and crystallised out lines of force, so that on the outer surface of the big bowel one saw developed tentacles of peritoneum, which attempted to connect or fix down the colon to the posterior abdominal wall. Much discussion had been going on about those bands. Some localised them and called them by different names, such as chronic meso-sigmoiditis, Jackson's membrane, while the part which held up the end of the small intestine they called Lane's kink. But there was really nothing to differentiate one from the other. It was said that some were inflammatory; some were congenital; but he (the speaker) said they were all acquired; they were evolutionary. In regard to this condition he knew he was absolutely right. The anatomy of the coal-heaver was as different from that of those following lighter occupations as ours was different from that of the higher ape. If a child's leg were broken, and it did not join at the proper angle, a new shaft was developed along the lines of force, and the old shaft disappeared completely. Nature did her best to keep the intestines out of the pelvis, the large intestine being the chief offender. It was kept out of the pelvis by these bands which were acquired. People asked why it was that this had

---

(*a*) Delivered at the inauguration of the Winter Session of the North-East London Post-Graduate College, Prince of Wales's Hospital, Tottenham, on Thursday, October 23rd, 1913.

never been observed or described before. The reason was that the surgeon had been accustomed to doing his operations through little holes, and he knew practically nothing of what was inside the abdomen. This led this type of surgeon to be as ignorant of actual conditions as was the physician; he got into the habit of doing certain routine operations; and instead of wondering whether he was doing the right thing, he simply argued and spread himself on the details of the operation. Almost anyone is capable of grasping details, but few appear able to grasp a great principle; indeed, the simpler the principle the harder it seemed for some to grasp it.

The first band developed was that on the left side. That picked up the bowel at the junction of the iliac colon with the pelvic colon. That was an extraordinary kink. In the female it frequently attached the left ovary, and after a time it enclosed that left ovary. Later, the ovary became cystic, and acquired a lining of its own, then bursting out of the nest in which it was developed, it formed a tumour. Woman had a longer abdomen and a bigger pelvis than the male; these were physical disadvantages, though he granted she had advantages over males in other directions. If she had a baby at intervals her prolapsed viscera are forced upwards out of her pelvis and are kept in that position for some time, to the great advantage of her drainage scheme. Should the woman not become pregnant at intervals the left ovary is frequently caught up in the developing last kink, when an ovarian tumour results which acts mechanically upon the prolapsed viscera in a manner precisely similar to a pregnant uterus. Neither the surgeon nor the obstetrician recognised the advantages to a woman of having an ovarian tumour. The last kink also served the purpose of preventing the return of fæces from the pelvic colon into the iliac colon. Many people, if their bowels did not act at a certain time of day, could not get them to act until the usual time next day, because the material ran again into the descending colon, and remained there, away from the pressure of the abdominal contents. That kink made the life of many women miserable, for it fixed down the bowel, secured and anchored the ovary, which could not get out of the way of the pressure exerted by the solid fæces in their passage through this constricted and immobilised segment of bowel. That explained the pain in the left groin experienced by these women.

The cæcum tried to get into the pelvis, and this band did its best to stop it. If one resolved in two directions at right angles the downward thrust of the loaded cæcum acting as the resultant of the parallelogram of forces, one found cystallised lines of resistance outside, which had been called Jackson's membrane; and inside a kink was produced which was named after himself. They represented an attempt by Nature to meet the person's peculiar relationship to his surroundings—*i.e.*, the maintenance of the erect posture from morning to night.

The big bowel was accustomed to deal with almost any filth, and the accumulation of these organisms there did little harm. Writing in 1903, Metchnikoff said he believed the large bowel was the cause of all the trouble and of progressive old age; he also said he believed that in the dim and distant future some surgeon would be found with courage enough to remove the big bowel. He (Sir Arbuthnot) had then been doing that for three years. Metchnikoff then sent one of his senior experts over to study the organisms in the big bowel. He (the speaker) saw Metchnikoff in Paris quite recently, and he did not appear to have changed his mind as to the big bowel being the primary cause of trouble. It was the primary cause in a sense, but only in that it produced a damming back of the contents of the small intestine, and a consequent infection of them by organisms with which this portion of the bowel was unable to deal effectually. This interference with the outflow into the cæcum was the cause of a very large proportion of disease, including certain varieties of heart disease, kidney disease, liver disease, disease of the thyroid, cancer of the breast. Nature's efforts to meet the altered relationship of the individual to surroundings were both interesting and curious, for everything it did was good in the beginning, but disastrous in the end. An ovarian tumour was, for a time, of immense advantage; it undid the patient's kinks, kept back the bowel, and so afforded comfort; but in the end it killed her. The band which produced the ileal kink at first supported the cæcum, but later it killed the patient, in that it produced a delay of material in the small bowel. He would say that the results of chronic intestinal stasis were divisible under three heads:—(1) Simple mechanical results. By damming back the material in the small intestine a pulling on the duodeno-jejunal junction was effected, and it became kinked. This meant that the duodenum became distended mostly in its first part: the other parts did not distend in anything like the same proportion, because they had the posterior abdominal wall behind them, and were embedded largely in fat and peritoneum. Therefore one would expect that the part to undergo change would be the first part. Then, in order to prevent a regurgitation of material into the stomach there was a spasmodic contraction of the pylorus. That pyloric spasm caused dilatation and hypertrophy of the stomach. The distension of the duodenum resulted in engorgement of the mucous membrane of the duodenum, especially the first part, and there was some hæmorrhage from it; later abrasion, and later still there was ulcer. Later, the heavy stomach caused a tearing strain on the concavity, producing in a similar manner engorgement, abrasion, ulceration, and finally cancer of the mucous membrane. It had struck some people as extraordinary why cancer of the duodenum was so unusual, whereas cancer of the stomach was constantly met with. The reason was that duodenal distension and duodenal ulcer was one condition the physician could cure, and he did so by leaving it alone. When a person was kept on his back the obstruction to the ileal effluent was relieved, and in consequence the abnormal distension of the duodenum ceased to exist, and the ulcer or abrasion tended to heal rapidly. Ulcer of the stomach was a different proposition. There was a spasm of the pylorus, which developed a hypertrophied stomach; and that stomach could not be emptied and freed from strain unless the spasm were relieved. Putting the patient on his back only partially relieved the strain. An ulcer of the stomach is, therefore, more chronic, and sooner or later is more liable to become infected with cancerous organisms. That had to be grasped thoroughly. The next aspect was that the obstructed small intestine was infected by organisms which it did not know how to deal with, and which fouled its contents. It was from the small intestine that all our food was picked up. It was carried to the liver and altered by that organ as far as it could. If the liver had too much to do, the person said his liver was at fault, but the fact was that organ was doing its best, and it was the best friend we have. If there was too much for the liver to do, filth got carried into the circulation. As that process was always going on, we were, more or less, all the subjects of chronic stasis. Following the infection up, it extended into the duodenum, and afterwards into the ducts of the pancreas, setting up the condition known as pancreatitis, usually considered as an independent entity. People said here was pancreatitis, and here was gastro-enteritis, but the fact was that all these processes occurred together. Every case of chronic stasis had an infected pancreas, just as he had an infected common bile duct and gall bladder with later gallstones, cholecystitis and cancer. Of course, the longer it existed the more serious it was. First the pancreas was indurated, then inflamed, and later it became cancerous; they were different chapters in the three-volume novel called "Chronic Intestinal Stasis." Unfortunately, when gallstones are present the surgeon is satisfied to remove them; but he had really left the cause of them, of which he is unaware, untouched. One thing which was extraordinary in the study of intestinal stasis was the different modes in which people reacted to that poison; and that seemed to vary entirely with the colour of the hair. A red-haired person seemed to possess an immunity not enjoyed by a black-haired person. That was borne out by a novel familiar to all, "The Story of Two Constipated Women, or The Light That Failed." No one was more observant than Rudyard Kipling, yet he did not know those women were constipated. The red-haired woman never lost her appetite, whether for food or sexually, and however ill she was she did not seem to give in. Light hair seemed to bespeak enormous powers of resistance, while dark-haired people seemed to give up the struggle almost at once. Nothing caused misery in homes so much as the effects of chronic intestinal stasis, and hence it probably does much to destroy the happiness of married life.

He passed on to the consideration of the second group of effects that results from stasis, namely, auto-intoxication. Poison in the system affected it at an early stage. If one wanted a barometer indicating the degree of stasis in a woman, one had only to feel the upper and outer zone of the left breast. A surgeon would say it was chronic interstitial mastitis. Later, this degenerative condition extended to the right breast and affected the whole of it. If it persisted, that change became cancerous. Except in the case of syphilis, he believed it was impossible for anyone to develop cancer, except in the presence of chronic intestinal stasis.

The thyroid tended to degenerate and to diminish in size at an early stage in this condition, so that in an advanced case it could no longer be detected, and every ring of the trachea could be distinguished by the finger quite easily. The people who suffered from auto-intoxication also lost their fat and the muscles became flaccid, and that spelt disaster to a woman. Her uterus normally was stuck up because of the firmness of its muscular structure and of its supports. It was also largely supported by fat; but bereft of fat and with the muscles flabby, it turned over and sat on the rectum, when it became large, engorged and later inflamed. During defæcation it pressed on the large bowel and increased the difficulty of its evacuation. The gynæcologist only existed because women were static; and much the same applied to the physician and surgeon. The kidneys became mobile for the same reason. At first they did not do much harm, but later the effluent of urine or blood was interfered with, and certain definite changes ensued. The condition of the skin was also of great importance; it was stained brown, became smelly and offensive, and little wrinkles came into it, while in the case of women, hair began to appear in undesirable places.

Dr. James Mackenzie had dealt so fully with the conditions of the heart resulting from auto-intoxication that no further notice was required from him of the details; Mackenzie had had advantages which few consultants could expect to have. The general practitioner did more to move on the surgeon and the physician than anybody else in the world; he was infinitely more important to progress than the specialist, only he did not realise it. The general practitioner lived with his patients, saw them from day to day, whereas the consultant saw a patient for, perhaps, twenty-five minutes. Mackenzie saw that the heart changes met with were due to a poison in the circulation, the poison being the product of chronic intestinal stasis. The extent of a person's belief could not be judged better than by his actions, and recently Dr. Mackenzie sent a patient to Guy's because he believed the heart condition was due to chronic intestinal stasis, which he thought would be benefited by removal of the large bowel. He, Sir Arbuthnot, did that, and now her heart condition had been completely relieved. And if one examined these cases in the way Dr. Jordan would presently show—and Dr. Jordan had been of immense help to him in showing him things he had only suspected, but could not demonstrate—it would be seen that they had changes in the left heart; the aorta was big and bulbous, hypertrophied and atheromatous. The Englishman had a craving to fight the faults of his drainage scheme by always taking exercise, the only reason for that being that he felt fitter when he took exercise. He was really only fighting his drainage scheme. Now we know he need only take paraffin to do that infinitely more effectually and not at the cost of serious damage to his vascular system. There were very few athletes of any degree of physical fitness by the time that they reached their fortieth year; they were only too frequently as static as they could be, they had an aorta of the consistence of leather, and their vessels were hard, so that no insurance company would look at them.

Many diseases of the kidneys also were due to chronic intestinal stasis. The kidney, like the liver, did its best for its owner, but in time it became diseased and had to give up the struggle. The physician called it Bright's disease, and proceeded to divide up the naked eye conditions found at autopsy. But one's concern should be to check the whole process.

He might reasonably be asked what evidence he had for these various statements. He had many friends on whom he had operated. A friend came to him, having seen and been intimate with most of the well-known medical people in town. He was passing quantities of albumen and casts, and was developing signs of uræmia. Dr. Jordan showed that he had a big left heart and aorta, an obstruction in his iliac colon—which some of his surgical friends had consoled him by saying was cancer. He had besides all the changes which result from intestinal stasis in an advanced degree. The patient and he talked the matter over, and he, the speaker, suggested doing a short-circuiting operation. This was done, the physicians making no objection, as they said he had got to die, and the difference would only be a matter of time. That was more than two years and a half ago, and his blood pressure, which at that time was excessive, was now normal; no albumen could be found in his urine, and he was doing 14 or 15 hours' work a day, and was feeling perfectly well. Some physicians believed in drugs, some preferred "watching," and he was not sure that the latter had not the better of it.

He would mention another case. Six days ago he saw a lady who was obviously dying; her pulse was almost imperceptible. She was in the hands of one of the most capable general practitioners he had ever come across, and he was associated with two consultants, one of whom had deservedly a world-wide reputation. The latter was of opinion that the patient was dying of gastro-duodenitis. Another opinion was sought, and that was that there was no gastro-duodenitis, but the patient was dying of pancreatitis, as the physician said he could feel the pancreas. There was no question that the patient had pancreatitis, gastro-duodenitis, and a host of troubles, and it was obvious that dissolution was immediately imminent. It was decided to short-circuit the patient and free the ileal effluent. Up to that time the patient had been vomiting almost incessantly; nothing given to her by mouth or rectum or under the skin did good. She had not vomited in the six days since the operation, and she was still alive, though admittedly when he saw her she had not 24 hours of life left.

He did not believe the profession had any idea of what the future of this line of treatment was going to be. In consequence of the depreciation of the vitality of the tissues by poisonous products organisms got a foot-hold and flourished, which otherwise could not have done so. Unless a person was toxic he could not have what was variously called rheumatoid arthritis or rheumatic gout. If in such a case the large intestine were removed, or the ileum were cleaned up, the case would at once begin a rapid improvement obvious to everybody.

Then in regard to tubercle. For a long time extensive operations were done for tubercle, until the habit was formed of treating surgical tubercle as if it were cancer. He had not now operated upon an advanced case of a tubercular joint for a long time. If such a person did not get well with paraffin—and many did—their drainage scheme should be altered, and then they would recover. In any case, it gave anyone a fighting chance.

Exophthalmic goitre, enlargement of the thyroid, either general or by adenomatous masses, were presumably superadded infections in that the removal of the big bowel had invariably resulted in their disappearance, and apparently in the complete recovery of the patient.

When one came to study the subject, it was astonishing what influence intestinal stasis had in the production of crime; one should note the mental effect of the poison is most remarkable; people who had it were grossly irritable and difficult to live with. He could understand a man preferring to live with a drunken woman rather than a toxic one; a drunken person was occasionally merry, but a toxic person never. When in Chicago a woman was brought to him into whom a man had pumped lead in the shape of seven bullets. They said they were going to destroy the man, but after seeing the woman he, the speaker, advised them to take away the woman's large bowel, and restore happiness to a home, and not waste the man's life.

The operative treatment of the condition consisted of two things: (1) facilitate the passage through the obstructions by means of paraffin and some mechanical support, which by exerting pressure on the abdomen would keep the intestines in place to meet the assumption of the erect posture. (2) Free the ileal effluent by operation, cutting through the ileum, and putting it into the end of the big bowel. There might be some discomfort in a distended cæcum, but his simple rule was that if the intestine was very loose he took it away, and joined the end of the ileum to the end of the big bowel, while if fixed in good position he left it alone.

With regard to the mortality of cases in which this operation was done, he preferred that others should give the figures, as a number of his friends appeared anxious to make out that his mortality was terrific. In order to have a perfectly unbiassed statement of fact, he had asked Dr. Baimbridge, of New York, who was greatly interested in the subject, and had come over from America, to speak on the subject of his statistics, into the question of which he had very carefully gone.

[Note. — The seventeen cases shown and described after the delivery of Sir Arbuthnot Lane's lecture we propose publishing in our next week's impression.—Ed. M.P. and C.]

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this Journal. The lecture for next week will be by Eric Pritchard, M.A., M.D., M.R.C.P., Senior Assistant Physician to the Queen's Hospital for Children; Physician to Out-Patients', City of London Hospital for Diseases of the Chest, Victoria Park; Hon. Physician for Infant Consultation, St. Marylebone General Dispensary, &c. Subject: "Some Common Disorders of Nutrition in Infancy."*

ORIGINAL PAPERS.

REMARKS ON THE LOCALISATION OF INTRACRANIAL TUMOURS. (a)

By T. GILLMAN MOORHEAD, M.D., F.R.C.P.I.,
Physician to the Royal City of Dublin Hospital.

The subject of the localisation of intracranial tumours is so vast that an introductory paper such as this can only attempt to deal with it in the most superficial way.

I propose to plunge *in medias res*, to leave out all historical points, and to attempt to be as practical as possible. I begin with tumours of the frontal lobe, meaning by the term frontal lobe the region of the cerebrum that lies anterior to the pre-central sulcus. Experimental work on this region of the brain has been almost uniformly negative in results. Occasionally visual disturbances and impairment of movement on the opposite side of the body have been noted, but these occurrences have been too inconstant to allow us to conclude that they are anything but accidental. A fairly careful search through the literature enables me to present, however, the following list of symptoms as suggestive of frontal involvement, the classical symptoms of headache, vomiting, and optic neuritis being also present in almost all cases:—

(1) Mental; general obtuseness with recurrent attacks of coma; sometimes irritability, or more often, according to Oppenheim, a tendency to jocularity; the memory is usually much impaired, especially for recent more or less trivial events; the patient is emotional and has lost his sense of decency.

(a) A paper read to introduce a discussion on intracranial tumours.

(2) Tremor of homolateral limbs.

(3) Spasticity of limbs on opposite side due to pressure on motor centres.

(4) Incontinence of urine.

(5) Ataxic gait without change in the reflexes.

(6) Unilateral anosmia, and perhaps unilateral optic neuritis.

In addition pain on pressure over the frontal region, and sometimes an obvious local swelling in the same region has also been noted.

In glancing through this list of symptoms it will be at once noted that the mental ones predominate. According to Hollander, who has recently published a book on the mental symptoms of brain tumours, the frontal lobes are those which are most poorly developed in microcephalic idiots, and in accordance with this view mental symptoms should be expected in most cases of frontal tumours. This is in accordance with popular professional beliefs. The tendency to jocularity seems to be specially pronounced, and such a symptom should always direct the attention to the frontal lobe, especially if combined with loss of memory. The ataxia included in the list was present in the case that I will immediately refer to, and may be so pronounced as to suggest a cerebellar lesion, as in a case of Ferrier's, and as in my own. It has indeed been attributed to a backward pressure on the cerebellum, but such an explanation is to my mind quite unsatisfactory. Anosmia and unilateral optic neuritis if present are most important localising signs.

The following case, though complicated by the existence of a cyst in the occipital lobe, illustrates to some extent the symptoms caused by a frontal growth. The patient, a man, æt. 42, was admitted complaining of headache and of difficulty in walking and standing. Five weeks previously he had fallen in the street, and since then had suffered from headache, had a tendency to vomit, and had felt a difficulty in steering himself properly when walking owing to a tendency to fall to the right. His past history was unimportant. Examination showed a slight spastic condition of the legs, with brisk knee-jerks; there was no ankle clonus, plantar reflexes were normal, and there was no atrophy. The arms were normal, with the exception of a slight amount of inco-ordination on the left side. There was an irregular ataxic gait with tendency to fall backwards and to the right; no sensory disturbance; cranial nerves normal, except that there was optic neuritis, severe on the right side and less marked on the left; there was no nystagmus. The patient's mental condition was at first dull, but later he brightened up, and at times was quite humorous. There was incontinence of urine. The diagnosis seemed to lie between a tumour of the frontal lobe and one of the cerebellum, and owing to the serious condition of the patient it was decided to do a simple decompression operation at once, and to leave the question of removal of the growth for later on. Accordingly Mr. Henry Moore operated, and on turning down a bone flap, a cyst projected into the posterior part of the wound from the occipital region. Enlargement of the wound in this direction enabled a large cyst to be evacuated. Temporary improvement resulted, but the patient after a few days again sank into a dull, almost comatose sleep, which was only partly relieved by opening up the wound, and letting out an accumulation of cerebro-spinal fluid. Intense universal hyperæsthesia developed, so that the slightest touch made him scream out, and soon after signs of cardiac failure developed, and caused death three weeks after the first operation. The autopsy showed a large sarcoma in the right frontal lobe, and a much smaller one, part of which had given origin to the cyst, in the occipital lobe. The unexpected finding of this cyst at operation not unnaturally upset one's views of the case, otherwise the ataxia, the occasional jocularity of manner, the one-sided optic neuritis and the incontinence of urine could not have failed, as they actually did before operation, to suggest involvement of the frontal lobe.

Rolandic Region.—This region may be dealt with briefly: convulsive movements or paralysis of the opposite side of the body, either localised or general, depending on the nature (destructive or irritative) of the lesion, and on its extent, are the symptoms to be expected. Motor aphasia when the lesion is on the left side is also frequently met with. Into the vexed question of localisation of sensation in the Rolandic area it is impossible to enter, but I may say that there is clinical evidence against such localisation. If sensation is impaired, along with motor paresis, and particularly if the power of localisation of sensation is interfered with, a phenonemon characteristic according to Horsley of involvement of sensory fibres above the optic thalamus, it is likely that the motor fibres of the internal capsule are those involved, and not the cortical cells. Tonic spasms of the opposite side will then be present, instead of the epileptiform storms characteristic of cell stimulation. If the internal capsule is involved hemiopia may also be expected, so that the triad of hemiplegia, hemianæsthesia and hemiopia may all be found. Thus in a case of my own some years ago paralysis of the left leg with weakness of the left arm, loss of tactile sensation in the left leg, and loss of the left half of the visual field were associated with a glioma in the posterior part of the right internal capsule. It is only right to add, however, that in two cases of tumour of the corona radiata under the Rolandic area, I have seen epileptiform convulsions, probably resulting from pressure on the Rolandic cells. Before leaving the subject of sensation it may be well to state that the falciform lobe, and particularly the gyrus fornicatus, is still regarded as the cortical site for sensory perceptions.

Parietal Lobe.—Very little can be stated regarding the localisation of tumours in the parietal lobe. Hollander advances the view that the mental condition of melancholia is associated with parietal disease, but fails to my mind to prove his thesis. Hemiopia and ptosis on the opposite side when the angular gyrus has been destroyed have been observed in a minority of cases, but the only sure localising sign is word-blindness, which exists when the inferior parietal lobule of the left side is implicated. The distinction between cortical and sub-cortical word-blindness would involve a discussion too prolonged for this summary, and as the sub-cortical variety is extremely rare, such a discussion would be of little value.

As regards tumours of the *occipital lobe*, still less can be stated. Hemiopia may be present, but more often such tumours are entirely silent, except for the production of the classical symptoms of increased intracranial tension. Even if hemiopia is present, moreover, it is impossible to state in what part of the optic radiations or occipital cortex the lesion is located. Wernicke's pupillary reaction may enable one to prove that the hemiopia is produced by a lesion further back in the visual path than the optic tract, but further than this it is often impossible to go, unless associated symptoms pointing to involvement of the internal capsule are also present.

In the case already described in which a cyst was present in the occipital lobe there was no hemiopia, and it is probable that few if any of the symptoms were actually caused by the occipital growth.

Temporal Lobes.—Hollander, whom I have quoted before, states that ferocity and bulimia are often found in association with temporal lesions. I refer to his work not because I always agree with his conclusions, but because he has attacked the problem of cerebral localisation from the mental aspect and believes that much knowledge may be gained by careful observation of mental peculiarities in patients suffering from intracranial disease. Word deafness, as is well known, is associated with lesions of the upper left temporal convolution, and is the only reliable sign of involvement of the temporal lobe. In one case I have seen in which a temporal tumour was found, subjective gustatory symptoms were present, and such symptoms are always suggestive, but their presence is the exception.

Cerebellum.—In dealing with the diagnosis of cerebellar tumours we approach a part of the brain which, though disappointing from an experimental point of view, yields as a rule definite clinical symptoms when extensively diseased. For a careful analysis of the symptoms of cerebellar tumours we are indebted to Grainger Stewart and Gordon Holmes. Their paper has been most useful to me personally, and I cannot do better than rapidly summarise their results. Headache, occasionally situated over the cerebellum, vomiting and optic neuritis are practically invariably present. Vertigo with a definite sensation of movement of surrounding objects and of the patient himself, and attacks of giddiness are common. Nystagmus is almost invariably present, and this symptom in tumour cases should in my opinion always suggest a localisation of the growth in the posterior cranial fossa. In strictly intra-cerebellar tumours nerve involvement is often absent, but on the other hand facial paresis, and some weakness of the external rectus muscle, and possibly involvement of the sensory and motor fibres of the trigeminal, may be encountered. Obviously also the auditory nerve may be compressed. Weakness of the limb muscles amounting to definite paresis may be found on the side of the lesion, and is usually accompanied by some degree of ataxia. A special form of this ataxia is sometimes seen in an inability to pronate and supinate the forearm on the side of the lesion with rapidity, the power to do this being retained on the opposite side. This symptom I have seen well marked in one case of cerebellar growth. The gait is of the familiar drunken type, with a tendency to deviate towards and to fall towards the side of the lesion. Reflexes are variable, but as a rule are increased, and usually sensory symptoms are absent. When the tumour is in the vermis of the cerebellum, the ataxia is of a more bilateral character and the patient may have a tendency to fall either forwards or backwards.

In extra-cerebellar tumours very similar symptoms may be found, but as a rule there is more evidence of nerve involvement. Deafness and tinnitus aurium may be present. Nystagmus is the rule, and muscular tremor on both sides of the body may be met. On the other hand the homolateral paresis described in cerebellar tumours is often absent, while spastic paralysis of the contra-lateral muscles due to pressure on the motor tracts is not infrequent.

If the *pons* or *medulla* be the site of the growth the diagnosis depends on an intimate knowledge of the cranial nerves that may be involved. I can do no more than point out that in pontine tumours a crossed paralysis, the limbs on one side, and the fifth, sixth and seventh nerves on the other, is most likely to be found, while in medullary tumours paralysis of one side of the tongue and of the opposite side of the body may occur. Wide variations, however, are met with, which will be sufficiently obvious to those who are familiar with the intimate anatomical structure of the pons and medulla. If, for example, the vomiting centre in the medulla be irritated, vomiting may be an early and persistent symptom in a degree more pronounced than can be accounted for by increased intracranial pressure. Again, glycosuria is by no means rare with pontine tumours, and dysphagia with bulbar ones. What I have here stated regarding the pons and medulla applies also to the *crura cerebri*. A knowledge of the anatomy of the crura leads one to expect the so-called Weber syndrome in tumours of one crus, namely, paralysis of the oculo-motor nerve on one side, and of the face, arm and leg on the opposite side, and such a syndrome has comparatively often been observed. When the *corpora quadrigemina* are attacked ataxia of cerebellar type with a tendency to fall forwards, paralysis of one or both trochlear nerves, and possibly also of the oculo-motor nerves, are, according to Williamson, the diagnostic symptoms. Disturbances of vision and of hearing might be expected, but are by no means always present.

I have now briefly skimmed over most of the regions of the brain, and have only left the *central nuclei* and the *corpus callosum* to deal with. Of the former little positive can be said; lesions, either of the *corpus striatum* or of the *optic thalamus* may be entirely latent, or, on the other hand, by involvement of the *internal capsule* may give rise to hemiplegia and hemianæsthesia. Athetoid movements are stated to be specially associated with thalamic lesions, and marked elevation of temperature with those of the corpus striatum, but neither statement can be regarded as more than speculative. As regards the corpus callosum, the absence of other localising signs, hemiplegia on one side, and hemiparesis on the other, are stated to be suggestive, but nothing more can be said. Commonsense will, however, occasionally lead one to an accurate guess, as in a recent case of my own in which a growth of the genu of the corpus callosum pressing on the optic chiasma was diagnosed correctly from the presence of very intense optic neuritis unassociated at first with other signs of intracranial growth. In this case there was a very pronounced intention tremor, with slight general increase of reflexes, so that the case bore a resemblance to disseminated sclerosis. The occurrence later on of headache, the pronounced optic neuritis and the absence of other signs of sclerosis enabled, however, a correct diagnosis to be arrived at.

Of tumours of the *pituitary body* I need not speak, further than to say that over and above the characteristic acromegalic symptoms, headache, vomiting, and optic neuritis with special involvement of the inner half of each retina, are frequently found in acute cases.

In conclusion I may say that in presenting this brief summary I have been compelled to omit all reference to the obvious fact that tumours may involve more than one part of the brain, and also that multiple tumours are by no means uncommon. A remembrance of these facts will help to explain the many difficulties that are encountered in diagnosis. In attempting to present localising signs, moreover, I have perhaps given the impression that a majority of tumours can easily be localised. This is, of course, not the case. Tumours occurring even in such parts of the brain as the Rolandic region may be entirely unaccompanied by localising signs, doubtless owing to their slow growth, and the consequent adaptation of surrounding structures to their presence. Into minute details I have also been unable to go, as to do so would necessitate a preliminary careful anatomical statement regarding the position of the various cranial nerves. I may, perhaps, here, however, state that my experience coincides with others in regarding paralysis of the sixth nerve as comparatively unimportant from a localising point of view. Its long intracranial course in contact with bone renders it peculiarly liable to suffer in all cases of increased intracranial pressure. Lastly, as far as I have seen, Horsley's contention that optic neuritis is most marked on the side of the growth is almost invariably correct, and is a most valuable observation in determining the side of the brain on which, when accurate localisation is impossible, a decompression operation should be performed.

ANÆSTHESIA—INTRATRACHEAL METHODS. (*a*)

By H. EDMUND G. BOYLE, M.R.C.S., L.R.C.P.,

Senior Assistant Anæsthetist and Demonstrator of Anæsthetics to St. Bartholomew's Hospital, London.

INTRATRACHEAL ANÆSTHESIA.

Intratracheal Insufflation of Ether.

Amongst the recent advances that have been made in anæsthetics, the intratracheal insufflation of ether fills a long felt want.

In the past, surgeons were loath to attempt operations which entailed free opening of both pleural cavities, for fear of sudden pneumothorax, and probably death of the patient, and so such operations were left to those men who were able to use negative pressure cabinets. Now, however, thanks to the work of Meltzer, Auer and Elsberg, these cabinets can be dispensed with, and a safe and satisfactory anæsthesia obtained for intrathoracic operations, by means of the intratracheal insufflation of ether.

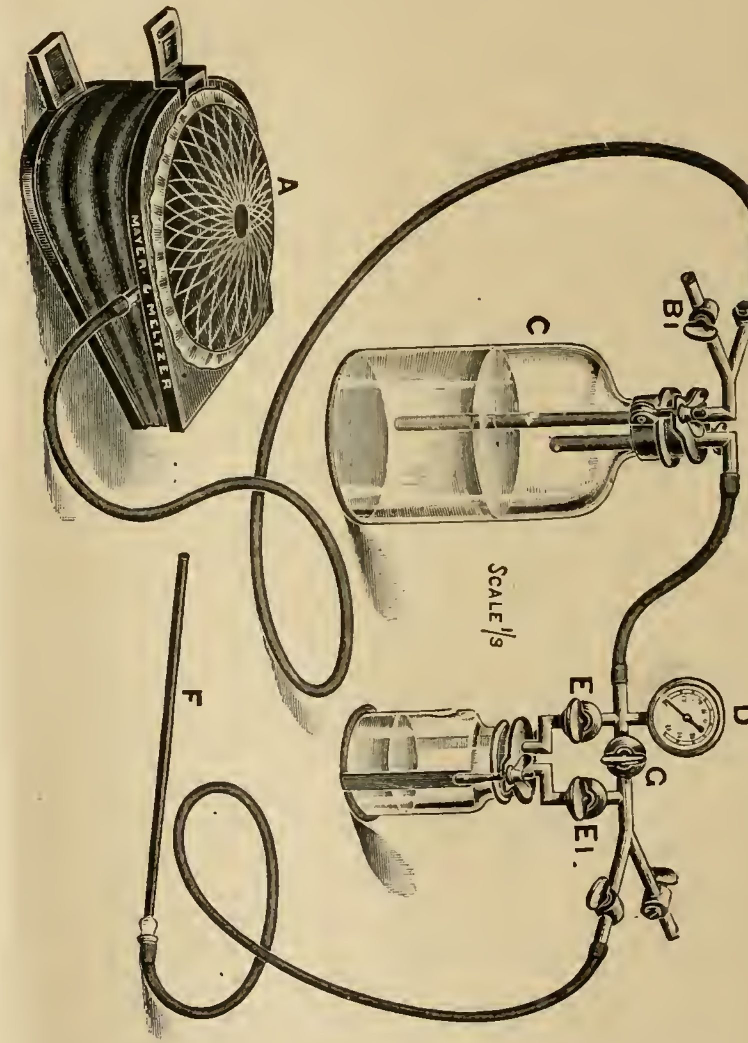
The importance and value of Meltzer's experimental work, and its subsequent adaptation for use in the human subject, cannot be too highly estimated, for it permits of operations being performed, with safety, for the relief of suffering, which were otherwise impracticable.

My interest in this subject was first aroused by my colleague on the surgical staff at St. Bartholomew's Hospital, Mr. George E. Gask. He desired to perform operations within the thorax, and wished me to administer the anæsthetic.

Thanks to the courtesy of Dr. Silk, we were enabled to thoroughly examine an Elsberg apparatus that he had at King's College Hospital, and we came to the conclusion that this was rather large and complicated, so we devised the simple and efficient apparatus which is here depicted, and which I have here for you to see.

The Apparatus.

Air is driven by means of the foot-bellows A through the tap B into the larger bottle C (which contains hot water), then on through tap E over the surface of the ether in the smaller bottle, and so on through EI to the catheter F.



BI is a reserve tap for oxygen, if necessary. The manometer D shows the pressure under which the air is being driven towards the trachea.

The method of administration is as follows:—The patient is first anæsthetised with gas and ether, and a fairly deep anæsthesia obtained. A deep anæthesia is necessary in order to facilitate the introduction of the catheter. My method of introducing the catheter is to pull the tongue forward, pass the index finger over the epiglottis, and then pass the catheter along this finger, and so through the vocal cords. This manipulation requires a certain amount of practice, and I have noticed that my only cases of sore throat after the operation were in patients in whom the introduction of the catheter was very difficult, and in whom, in consequence, there was a good deal of fingering of the epiglottis and the neighbouring parts. As soon as the catheter is in position it is connected up to the exit tube of the apparatus, and air laden with ether vapour is pumped in.

The anæsthesia is light in character, but distinctly good: the corneal reflex is usually present, and the patient keeps a pink colour. Cyanosis,

---

(*a*) Paper read at the International Congress of Medicine, London, August, 1913.

when it occurs (and it is rare) is, I think, due to too large a catheter, but this can easily be remedied by using one of smaller diameter.

The cases that I have anæsthetised by this method differ widely in their character. They include:—

Operations for goitre	12
Intrathoracic operations, including empyema and abscess of lung	8
Œsophagoscopy for removal of tooth plate	1
Ovariotomy and laparotomy, including appendix	7
Excision of kidney	1
Submucous resection of septum nasi ...	1
Amputation of breast	2
Cervical rib	1
Other operations	12
	45

There has been one case of broncho-pneumonia, following an operation for goitre, and one case of bronchitis also after operation for goitre.

Two cases of sore throat, in both of which there was considerable fingering of the epiglottic region.

Although I have only used this method on a comparatively small number of cases, yet they have been sufficient to satisfy me that this method is one of great value; and whilst I do not advocate its use for ordinary cases, I think that for intrathoracic operations, operations on the thyroid gland, and generally for neck operations, it has a future that few of us can estimate.

The easy anæsthesia, the comfort and safety of the patient, both during and after the anæsthetic, must, I think, appeal strongly to all those who have to deal with this branch of the profession.

SOME USES AND ABUSES OF VACCINE THERAPY.

By D. MOORE ALEXANDER M.D.,
Assistant Lecturer in Bacteriology, University, Liverpool;
Medical Officer in Charge of Vaccine Therapy Department,
Royal Southern Hospital, Liverpool.

A Vaccine Therapy Department attached to a hospital serves at least three useful functions. In the first place, it allows the hospital physician and surgeon to clear the beds of subacute and chronic cases by turning them into out-patients; into this category fall those suffering from such conditions as appendix sinuses, surgical tuberculosis, chronic osteomyelitis, chronic bronchitis, pulmonary phthisis with secondary infections, and chronic bacilluria. Secondly, persons suffering from obscure chronic infections may be sent to this department for bacteriological diagnosis. Thirdly, individuals who cannot afford vaccine treatment at home can come as out-patients and obtain an autogenous vaccine or a course of tuberculin without cost.

The following table, showing the nature of the cases treated and the results obtained, concerns the work of the Vaccine Therapy Department of the Royal Southern Hospital for the period of one year, May, 1911, to May, 1912—the first year of its existence.

Organism.	Nature of Case.	Result.			
		No.	Cure.	Improved.	Unaltered.
B. coli (or coliform organism).	Mucus colitis	4	2	1	1
	Appendix sinus	5	4	0	1
	Hydatid sinus	1	1	0	0
	Bacilluria	6	2	0	4
	Total	16	9	1	6
Staphylococcus aureus.	Furunculosis	9	9	0	0
	Septic wounds and chronic skin conditions	5	4	0	1
	Osteomyelitis	7	6	1	0
	Tubercular sinuses	2	2	0	0
	Total	23	21	1	1
Staphylococcus albus.	Chronic urethritis	2	1	1	0
	Acne	1	1	0	0
	Periostitis (thumb)	1	1	0	0
	Otitis media	1	1	0	0
	Total	5	4	1	0
Streptococcus.	Pulmonary phthisis.	1	0	1	0
	Chronic bronchitis	1	0	1	0
	Otitis media	1	0	1	0
	Sinus of arm	1	0	0	1
	Total	4	0	3	1
Gonococcus	Rheumatism	3	0	2	1
	Joints	3	0	3	0
	Total	6	0	5	1
Pneumococcus.	Abscess about shoulder	1	1	0	0
Simple vaccines. Total		55	35	11	9
Staphylococcus aureus & B. pyocyaneus.	Sinus of heel	1	1	0	0
	Lymphangitis arm	1	1	0	0
	Total	2	2	0	0
Staphylococcus aureus & streptococcus.	Chronic pyæmia	2	2	0	0
	Cellulitis of neck	1	1	0	0
	Total	3	3	0	0
B. Friedlander and B. septus.	Chronic bronchitis	1	1	0	0
	Total	1	1	0	0
B. Friedlander and streptococcus.	Chronic bronchitis	6	4	0	2
	Chronic nasal catarrh	1	1	0	0
	Total	7	5	0	2
Mixed Vaccines. Total		13	11	0	2
Tuberculin	Surgical tuberculosis	19	14	5	0
	Pulmonary phthisis.	2	0	1	1
Tuberculin. Total		21	14	6	1
Simple vaccines		55	35	11	9
Mixed vaccines		13	11	0	2
Tuberculin		21	14	6	1
Total for year, May 1911 to May 1912		89	60	17	12

With the exception of the tubercular cases and those suffering from chronic rheumatism and joint lesions of gonococcal origin, conditions in which the preparation of a homologous vaccine is a matter of great difficulty, every case has been treated with an autogenous vaccine. The opsonic index has not been investigated in any case. Dosage has been guided entirely by clinical manifestations, and this has necessitated careful observation of individual reactions, especially at the initiation of a new case. It has been the custom to give the injections on Thursdays, whilst Tuesdays have been used mainly as a dressing-day, upon which the clinical condition of the wound was observed, and also, if necessary, as a supplementary day for inoculations. Hence it was possible to administer a second dose on the fifth, seventh, twelfth, or fourteenth day after. By this means it was possible to gauge the resistance of the individual and to standardise the routine dosage in a short time.

In discussing the results of the table, the most important and the most interesting, comprising the very cases from which the therapist learns the most, are the failures. They are twelve in number, nine of which have been treated with a simple vaccine, two with a mixed vaccine, and one with tuberculin.

The organisms specially concerned consist of the streptococci and the coliform bacilli, from which autogenous vaccines were prepared; gonorrhœal rheumatism and tuberculosis were treated with stock vaccines, and on this account must be placed in a separate class. More time and work has been expended upon the *B. coli* infections than upon all the rest together, and yet this group presents the greatest percentage of failures. The streptococci follow, and at first the connection between such widely differing bacteria is not obvious.

Streptococci occur normally in the mouth in considerable numbers, they are present normally but scantily in the fæces, and many infections of the larynx and lungs are caused by streptococci with or without an associated organism. The coliform organisms inhabit mainly the lower levels of the alimentary system, but appear to pass very easily into the genito-urinary tract, where they produce acute or chronic infections, the usual symptom being a bacilluria, which is commonly a coliuria of intestinal origin.

These two systems, the alimentary and the respiratory, are notoriously the most difficult to treat by immunological methods. The material derived from them, the stool and the sputum, always consists of a complex mixture of organisms, from which it is never easy to isolate the causal germ. When by laborious methods the proper bacterium is isolated and identified and the dosage discovered, the irresponsiveness of these particular tissues, when once injured, prevents advance.

There have been three theories advanced to explain this languid response to stimulus on the part of the intestinal tract and the lungs. One is based upon the idea that the interchange of the products of tissue activities between the dermal and muscular tissues on the one hand and the intestinal mucous membrane and lung epithelium on the other, is slow and at best very meagre. A second hinges upon the first theory, accentuating the fact that neither the respiratory nor the intestinal tissues possess much capacity, as far as is known, for tissue repair or for any great immunological response to stimulus. Thirdly, the blood arriving at these centres of acute metabolism suffers such severe and profound chemical changes that the antibodies it carries may, in the general decomposition and hydrolysis, undergo change also and be rendered ineffective. Whichever be the true view, the fact remains that, as a rule, infections of the digestive tract form a class of case which presents singularly difficult problems to successful vaccine treatment.

The cases of bacilluria, in the light of recent knowledge, may be placed amongst the digestive tract infections, certainly those which are caused by a member of the coli group. It is a common disorder in women, rare in men, and the female anatomy predisposes to intestinal infection of the genito-urinary tract. There must always be a grave suspicion that a bacilluria unaccompanied by pus, bladder, or kidney-cell sediment is an evidence, perhaps the only one at first, of an intestinal lesion and not of an inflammatory disturbance of the genito-urinary tract.

The gonococcal cases have all been disappointing; they were treated with a stock vaccine. A recent case in an acute stage from which the gonococcus was isolated and an autogenous vaccine prepared has, however, reacted rapidly to treatment. The cases of tuberculosis which have been listed amongst the improved cannot all be classed amongst the failures. Only two remain at the present date, in which the improvement has taken place extremely slowly. They have proved refractory to any increase of dose, and finally had to be treated by judicious shortening of the intervals which separated injections of an invariable magnitude.

It is difficult to answer the question whether vaccine treatment as a rule hastens the healing of chronic sinuses and other conditions. The data for a comparison with other methods of treatment are not obtainable; the duration of a discharging sinus depends entirely upon the condition of the individual case, the extent of the lesion, and the nature of the infecting organism. If treated with antiseptic lotions the patient will heal eventually; if carefully dressed and an autogenous vaccine administered the disease is being attacked from within as well as from without. The prognosis of a rapid recovery is favoured if the initial injections produce a good reaction; if little or no reaction can be elicited at the site of the lesion until large doses have been given, progress will be slow. It is not good policy to neglect any aid to treatment, and several stubborn sinuses have been treated with excellent effect with solutions of metaphosphoric acid and of allantoin, which were suggested by Dr. C. J. Macalister. A few sinuses have been induced to heal very suddenly by means of a trick. On the day following the injection of a large dose the discharge greatly increases, diminishes on the second day, and on the third day the sinus is found to be nearly dry. It is then subjected to a vigorous scraping with a sharp spoon, fills with blood, and is then sealed with a collodion plug. Two sinuses, one 1½ ins. deep, the other 2 ins., healed immediately under this treatment; two others were reduced in a week from 4 to 4½ ins. of depth to 1 and 2 ins. respectively. Bier's treatment, lavage with alkaline solutions, attention to the alkalinity of the blood, removal of irritating foci, removal of the possible sources of reinfection—all demand attention and application if the treatment is to produce rapid results.

Success in vaccine treatment depends upon certain factors.

(i.) The condition of the patient's tissues, whether, in fact, they are capable or incapable of response to an immunising stimulus.
(ii.) The identification of, and if possible the preparation of the vaccine from, the causal organism.
(iii.) The correct dosage—depending upon the virulence of the organism and the reactivity of the patient's tissues.
(iv.) The observance of the correct interval between doses, depending upon the response to the dose, the interval and the dose being mutually interdependent.

All failures in vaccine therapy can be attributed to the absence of one or other of these factors or to flagrant transgression of rules founded upon an interpretation of these factors.

(i.) The condition of the patient's tissues is placed first in this list as it is the fundamental factor. If the tissues are poisoned by the toxic products of the infecting organism to such an extent that they have no power of response, vaccine therapy, which depends primarily upon tissue-reaction, is hopeless. The great example of such a tissue state is found in the last stage of malignant endocarditis, and the late recognition of this condition is due to the obscurity of the disease and the difficulties it presents to clinical diagnosis in the early stages. Cannon, the authority upon the bacteriology of the blood, recognises three stages in the process of blood-infection. In the first stage the organisms are shed from some focus—teeth, nose, intestine, or superficial wound—into the blood, causing a rigor, destruction of the bacteria, and clinically an acute but transitory headache and general malaise. In the second stage the weaker organisms die out soon after entering the blood-stream, but the more virulent individuals contrive to exist for some time. The symptoms of this stage consist in a preliminary rigor or shiver, and a later typhoid state which lasts from a few hours or days to a week or ten days, but clears up as the organisms eventually perish. In the third stage, which synchronises with the last stage of the patient, the organisms exist and *develop* in the blood. By this time the tissues are poisoned, the bactericidal powers of the blood itself are depleted, and the picture now is identical with that of a septic endocarditis in its later stages. These three stages may succeed one another, with virulent infections, in a period of hours or days. More usually they require months to produce a fatal result. The rapidity of the sequence depends upon the virulence of the bacterium, the frequency of the incursions of organisms into the blood (if more than one be necessary to produce a fatal result) and the rate at which the patient's resistance declines.

In malaria it is recognised that a rigor signifies the incursion of sporulating parasites into the blood-plasma. Malaria being ruled out, a rigor *always* signifies an incursion of organisms or their toxins into the blood-stream; if this were more generally recognised, malignant endocarditis would be diagnosed earlier. It is hardly possible that it could be diagnosed in Cannon's first stage, but there are not insuperable difficulties to prevent its recognition or, at all events, a suspicion of its presence in the second stage. Diagnosis in the third stage is useless. Again, a high temperature, without a rigor, is generally indicative of the presence of organisms in the blood. The pneumococcus can be obtained by blood-culture in true pneumonia early in the attack, by the same method the typhoid bacillus can be recovered, in the first week of the disease, from 96 per cent. of cases, from 50 per cent. in the second week, and from 16 per cent. in the third week. No working bacteriologist attempts a blood-culture with much hope of success if the temperature be under 101° F. A persistent leucopenia in pneumonia or typhoid conduces to an unfavourable prognosis. Most cases with persistent leucopenia in bacterial diseases—a condition produced *always* and only by the permanence of organisms in the circulating blood—terminate fatally. The leucocytes therefore serve as important evidence for prognosis. They frequently, and this is extremely important, inform the bacteriologist of the worth or worthlessness of vaccine therapy. If the leucopenia alternates with a leucocytosis, that is sufficient evidence to him that the tissues are reacting and that a dose of vaccine may elicit a response. If the leucopenia is permanent and no fluctuations occur in any of the various types of white cells in relation to intermissions of temperature, he can expect little or no response to his injections; the tissues are poisoned beyond hope.

(ii.) The identification of the causal organism is a factor of an importance secondary only to the condition of the tissues. Yet it is the factor which is notoriously and frequently neglected, since it is considered easy to combine the bacteriological diagnosis with the clinical. If it be essential to be certain of the bacterium causing the lesion, it is equally important to keep the diagnosis up to date. Hence this second factor resolves itself into two:

1. An initial bacteriological diagnosis.
2. A periodical bacterial diagnosis.

It may be admitted frankly that the *Staphylococcus aureus* causes most boils and many cases of osteomyelitis and that a stock vaccine produces quite excellent results in many of these cases. It will be admitted that gonococcal infections can be diagnosed clinically and that a stock gonococcal vaccine *rarely* produces any result. But, having admitted the possibility of correct clinical diagnosis in these two infections, there is no other infection (certainly not tubercle) which can with safety and accuracy be diagnosed without the aid of bacteriological methods.

Take, for instance, the connection of the pneumococcus with pneumonia. Most clinicians and all textbooks have considered from time immemorial the acute inflammations of the lung called pneumonia as an evidence, in 90 per cent. of cases, of the pneumococcus; the remaining 10 per cent. may possibly be due to the *Bacillus pneumoniæ*, the influenza bacillus, a streptococcus rarely, the *B. typhosus* seldom, and the *B. pestis* in Oriental countries. The American Commission upon Respiratory Diseases has issued reports, however, prepared by a band of accurate investigators, showing that in only 50 to 60 per cent. of clinical pneumonias does the pneumococcus appear as the causal organism; and clinicians will be ready to admit that only 50 per cent. of their cases are typical.

Therefore, in at least 40 per cent. of pneumonias a pneumococcal vaccine is useless. But pneumococcal vaccines are adminstered right and left in every case of so-called pneumonia, even by mouth, and when no effect is produced the result is not attributed to ignorance but to the utter worthlessness of vaccine therapy.

If the mistaken percentage in pneumonia is 40 per cent. the corresponding number for *B. coli* infections is at least 1,000 per cent. There are four chief reasons, besides innumerable supernumerary reasons, for this. Firstly, the microscopic examination of a smear stained by some simple method has too often been deemed sufficient for the diagnosis of this organism. Even if a double stain be employed and the bacillus in the field prove to be Gram negative, it is not sufficient—there are at least thirty common Gram negative bacilli.

Secondly, the diagnosis of *B. coli* by laboratory tests is at present a matter of dispute amongst bacteriologists themselves. *B. coli* to the water analyst signifies an organism that will pass his two tests; M'Conkey requires four reactions at least, and he has recently extended his tests to six. With six tests, which depend mainly upon the production of acid and gas in sugar media, there may be theoretically 200 odd varieties of the coli group, none of which are true *B. coli*, but which differ from it in one or other small detail; but small and slight though this detail may be, it is frequently sufficient to distinguish between a pathogenic and a non-pathogenic organism. Now, 150 of these varieties have been isolated and described. Is it possible to peer down a microscope and identify which of these 150 is infecting the patient?

Thirdly, if a stock *B. coli* vaccine be supplied, it is a *B. coli* according to the favourite tests of the bacteriologist who prepared it. Again, if it be a polyvalent *B. coli* vaccine, it contains at the outside ten strains of the manufacturer's idea of what *B. coli* ought to be. If a *B. coli* serum be employed, the animal which furnishes it has been immunised with not more than ten or a dozen strains. A blunderbuss was popular in the Georgian era because its orifice was wide and its pellets outnumbered the assailants at whom it was aimed. But the polyvalent vaccine fulfils none of these functions. Its pellets in the case of the coliform organisms are outnumbered by at least fifteen to one, and the 150 of the enemy remain unharmed.

Fourthly, it is easy to isolate members of the coli group from human infections. It is easy to obtain many strains of coli variants from the same case. But it is one of the most difficult things in the world to determine which of the varieties isolated is the organism causing the symptoms. There are complicated methods to aid this diagnosis, but even those fail at times, and the task of preparing the vaccine from the important organism, which unfortunately is not invariably the predominant organism, is one of the most difficult falling to the lot of a bacteriologist.

The summary of the foregoing four paragraphs can be elucidated by the sentence: "There is no such thing as a *B. coli* in human infections." When Escherich in 1860 isolated an organism from an infant's stool, and light-heartedly endowed it with certain characteristics, he little knew what trouble he was storing up for humanity. The *B. coli* (Escherich) seldom occurs as a serious infective agent in men and women. The organisms which produce grave lesions in human beings are the brothers and sisters, cousins and second-cousins, of the original *B. coli*—Metchnikoff terms them the "wild races,"—and it is unwise to speak of *B. coli*, but perfectly safe to speak of a coliform organism.

The streptococci form a group whose members, however, are not so numerous nor so distinct as those of the Coli family. Gordon's differentiation of the various streptococci, by means of the fermentations of special sugar media, has not been confirmed by other observers, but it has been successful up to a certain point in that he has shown that there are four important classes with intermediates. The Germans distinguish three species according to their action upon blood-media. The evidences agree in the existence of different species of streptococci, and this in itself is inimical to the production of beneficial results by stock vaccines. The position here is not, however, so utterly hopeless as the one described under the heading of *B. coli.* The individuals of the streptococcal group cannot be so easily distinguished by chemical tests as were the coliform organisms, though animal inoculations aid in their differentiation. Again, they are few in number. Hence a polyvalent streptococcal vaccine (or serum) has an infinitely better chance of eliciting a beneficial response than any coli serum or vaccine. Streptococcal stock vaccines are rarely given, because there is a valuable serum prepared for this organism. It is used largely and promptly in early and late cases of clinical streptococcal infections. The percentage in which good results have been produced is small compared with the total number of cases so treated. The reason is simple. The clinical diagnosis of a streptococcal infection is not invariably correct.

This denunciation of the indiscriminate use of stock preparations has been confined to those of three organisms: to the pneumococcal vaccine because it is often used in inflammations of the lung *not* caused by the pneumococcus; to the coli vaccine and serum, because they are used as an unknown weapon against an unknown enemy; and to the streptococcal serum because of its hasty use in incompletely diagnosed infections. It would have been easy to extend this list—the *B. influenzæ* vaccine clamours for admission and the tuberculins deserve more than a mention—but space forbids. It is not denied that the stock vaccines of some organisms are useful, but of what use would they be to a man whose knowledge informs him that all pneumonias are pneumococcal, all appendicitis is due to *B. coli,* that there is only one streptococcus, and that the obscure cases require either 606 or tuberculin?

Hence vaccines are given to patients whose tissues are poisoned beyond all power of reaction, and the wrong stock vaccines are administered to those who are in a fit condition to benefit by the proper organism.

(iii. and iv.) The dosage and the interval are so closely bound up the one with the other that they cannot be discussed separately.

The correct dose is, in the first place, individual, and depends upon the reactivity of the patient and the virulence of the organism. Hence all initial doses must be small.

Effective doses are those which may produce a local reaction, and may produce a general reaction, but *do* produce a focal reaction, slight or severe. The interval depends *entirely* upon the focal reaction—local and general reactions are to be ignored in this connection.

By focal reaction is meant the disturbance at the seat of the disease. Local signifies the reaction at the site of injection; general, such symptoms as headache, nausea, rise of temperature, numbness of extremities, etc. The local and the general reactions are by-products. They usually run parallel with the focal reaction; but if they do not, they are to be disregarded in favour of the evidence furnished by the actual diseased spot itself.

It is the custom in a Vaccine Therapy Department to administer doses that will carry the patient over until the following week. Here the interval is subservient to the dose. But occasionally cases are met with in which the maximum dose is attained very early and any increase produces disastrous effects. Successful results can only be obtained in such circumstances by making the dose subservient to the interval. That is to say, the same dose is given with gradually decreasing intervals until finally a larger dose may be adventured. Disregard of this close interco-ordination of dose and interval is the cause of many vaccine failures.

The progression of a case normally synchronises with the progression of the dose, which rarely, except in a few obstinate cases, remains at a *status quo* for any length of time. The motto of vaccine therapy is "progression," and this may signify increase in dosage or diminution of interval; preferably an increase in the dose, since it has been proved that diminution of the interval is not so effective. The doses attained in the treatment of very chronic cases are sometimes very large. A dose of twelve thousand million staphylococci (aureus) has been given to a patient at weekly intervals—in this case no improvement was seen until the six thousand million mark was reached; this parenthetically forms another argument against stock vaccines, which are often stocked in ridiculously small doses. On the other hand, another case infected by the same organism deteriorated without any increase of dose over five hundred million, but progressed when the interval was lessened from seven to four days.

The essential factors upon which the whole system of vaccine therapy rests have been enumerated. It remains to summarise the chief errors that are perpetrated, which undoubtedly furnish the causes of many failures:

1. The want of early and accurate bacteriological diagnosis.
2. The use of stock vaccines in undiagnosed conditions.
3. The administration of vaccines without any regard for (1) the reaction, (2) the interval, and (3) the progression of the patient's immunity.

OPERATING THEATRES.

ST. BARTHOLOMEW'S HOSPITAL.

Appendicostomy.—Mr. D'Arcy Power operated on a domestic servant, æt. 34, who had been admitted for chronic constipation, with a history that six years previously she had been operated on by Mr. Power for acute hæmatemesis due to a gastric ulcer, at the Bolingbroke Hospital. Nine months before admission to St. Bartholomew's Hospital she had been treated for fæcal obstruction, and stated that she had not had a natural motion for three weeks. By enemata, followed by purgatives, the lower bowel was eventualy emptied, and the patient was discharged with a caution to be a little more careful in the future. On re-admission it was found that she had a fresh impaction of fæces, and she stated that in spite of all care she had had great difficulty in getting her bowels opened. Mr. Power therefore performed the operation of appendicostomy; the appendix was drawn out through a gridiron incision in the right iliac region. The base of the appendix was sutured to the peritoneum at the lowest part of the wound by a circular suture of No. 1 silk; the peritoneal and muscular coats of the abdominal incision were closed by catgut sutures. A track was made in the subcutaneus tissue of the abdominal wall, and a small incision was made through the skin at a point two inches below the end of the original incision. A pair of pressure forceps was passed through this small skin incision along the track until it emerged at the lower end of the original wound. The tip of the appendix was seized by the forceps and drawn along the subcutaneous track until it projected through the lower opening. The original incision was then closed, and the distal end of the appendix was secured to the small skin incision by two sutures of No. 1 silk passed through the serous, muscular and submucous coats of the appendix three-quarters of an inch from its apex, care being taken not to injure the vessels in the meso-appendix. The apex of the appendix was then divided on the side furthest away from the meso-appendix in such a way as to open the lumen and yet leave the apex attached to the main body of the appendix. A No. 6 soft rubber catheter was introduced into the appendix until its end lay in the cæcum, the partially detached apex of the appendix being used to steady the organ whilst the catheter was being passed. The first wound was covered with a collodion dressing. The patient was sent back to bed, and it was ordered that she should have oil enemata, and that the large intestine should be irrigated with salt solution through the appendicostomy.

Mr. Power said that the operation of appendicostomy was done more often for chronic inflammation of the large intestine than for chronic constipation. It was, however, a smaller operation than some of the heroic measures which had been recommended, but it remained to be proved whether it was as effectual. Experience has shown that the presence of a small fistula in the iliac region was not productive of much inconvenience in the majority of cases, for after appendicostomy there was a very small amount of discharge, it was not offensive, and did not need frequent dressing. The patient was able to irrigate the whole of the large intestine, and could thus prevent fæcal infection. It was necessary to keep a catheter or a small drainage tube in the opening of the appendix, as, without it, the sinus closed spontaneously. Two to three pints were usually sufficient for an irrigation, and normal saline solution appeared to answer the purpose best. The frequency of the injection must be regulated by the state of the bowels; it may be necessary daily or only once or twice a week.

In this case irrigation was continued daily for three weeks, and by that means the bowels were kept regular. The patient was then discharged from the hospital and was not seen again for exactly two years, when she came saying that she had had no further attack of fæcal impaction, and that she had continued to irrigate at irregular intervals until six weeks ago, when she had taken the tube out and allowed the sinus to heal.

TRANSACTIONS OF SOCIETIES.

ROYAL SOCIETY OF MEDICINE.

Section for the Study of Diseases in Children.

Meeting held Friday, October 24th, 1913.

The President, Dr. Leonard Guthrie, in the Chair.

Dr. C. E. Zundel showed two cases of

INFANTILISM.

The first was a girl, æt. 13. Eldest of three; others healthy. She was very small at birth, and "does not seem to have grown since she was five years old." Condition: Height, 3 ft. 6 in.; weight, 2 st. 10½ lb.; face intelligent; skin dry; hair fair, rather coarse; no suggestion of appearance of puberty. Urine: Acid, pale, specific gravity 1004, contains 1/20 albumin, and a few granular and fatty casts are found in the centrifugalised specimen. No polydipsia; occasional nocturnal eneuresis.

The second case was a boy, æt. 13. Since the age of 2½ years he has had polydipsia. No other illness before or since, but his excessive thirst has been constant. His father and one brother also suffered from diabetes insipidus. Condition: Thin, childish; weight, 2 st. 1½ lb.; height, 3 ft. 6 in.; thymus, thyroid and pituitary gland apparently normal. Drinks on the average 14 pints per diem. Dislikes sweet things; appetite is poor. Urine: Specific gravity 1001, no albumin, no casts, urea 0.5 per cent. Wassermann reaction negative.

Dr. E. A. Cockayne showed a case of

CONSTRICTION OF THE ARM BY AMNIOTIC BANDS.

The patient, a girl, æt. 3½, showed a narrow fibrous band completely encircling the right upper arm, causing slight constriction, and another which deeply constricts the forearm just above the wrist. In flexion—the intra-uterine position—the two scars are at the same level. The scar tissue is adherent to the deeper structures and the bone feels grooved, but a skiagram shows that it is not involved. The right arm and hand are well developed and larger than the left, showing that there has been no pressure on the arteries.

Dr. Cockayne also showed a girl, aged 1 year 4 months, with

HEMIPLEGIA

and a very extensive nævus. The birth was easy, but the child is said to have been "born in convulsions." The mother attributes the condition to her having seen a cripple with a very large birth-mark when she was three months pregnant. The mother noticed the nævus at birth, but is not sure whether the hemiplegia was present then or came on later. It was first noticed after the child had had a severe left-sided fit at the age of six weeks. She has had similar fits at intervals up to the age of one year. There is complete left hemiplegia with spasticity of the arm and leg, and the left side, including the face, is noticeably smaller than the right. There is very extensive port-wine staining of the skin of the scalp, face, arms, legs, and part of the trunk. It is fairly symmetrical and follows a posterior root distribution. Wassermann's reaction is negative.

Dr. Porter Parkinson showed a boy, æt. 5, with

RHEUMATOID ARTHRITIS.

In July, on admission to hospital, he was pale and thin, with wasted muscles. The knees, ankles, wrists and elbows were swollen and spindle-shaped, with soft, pulpy swelling. Enlarged glands could be felt in the axillæ and groins, but the spleen could not be felt and showed no evidence of enlargement. Teeth good; no evidence of gastro-intestinal derangement. Weight, 2 st. 1 lb. Wassermann and von Pirquet's reactions normal. Temperature occasionally up to 100° F. He was treated by massage, etc., a course of arsenic internally, and, later, by rectal injections of polyvalent anti-streptococcus serum, without effect. He left the hospital at the end of July, and on readmission in October, in addition to the conditions described above, there were spindle-shaped enlargements of all the joints of the fingers and slightly of the metacarpo-phalangeal joints of both hands, and the left hip joint had become fixed in partial flexion.

Dr. T. R. Whipman showed three cases of

UNDER-DEVELOPMENT.

(1) A rickety boy, aged 2 years 3 months, who was very undersized, being only 2 ft. high and weighing only 11 lb. The anterior fontanelle is open, and the patient has only seven teeth.

(2) A boy, æt. 8, of diminutive stature, but well-proportioned and intellectually bright. Height, 2 ft. 9 in.; weight, 1 st. 8½ lb. He presents no signs of rickets, but suffers from tuberculosis of the skin and subcutaneous tissues. He has been treated with thyroid extract, and more recently with polyglandin with some improvement.

(3) A girl, æt. 18, showing signs of hyperthyroidism. She has now the development of a girl aged 10, her height being 4 ft. 1½ in., and her weight 4 st. 10½ lb. There is an absence of mammary development, also of both pubic and axillary hair, and menstruation has not occurred. The girl has attended school, but was not quite up to the normal standard and her memory is not good.

Dr. Whipham also showed a girl, æt. 6, with

ENLARGEMENT OF THE LIVER AND SPLEEN ASSOCIATED WITH JAUNDICE.

The patient was born jaundiced, the colour being "green-yellow," and the condition lasted for six weeks. Since then no jaundice has been noticed until February of this year. The onset was sudden, and when the patient was first seen in May she was deeply jaundiced, being of an olive-green colour all over. The liver was greatly enlarged, extending to the umbilicus, and the spleen was also of considerable size, extending down to the same level. The blood-count at this time showed: red corpuscles, 4,824,000 per c.mm.; white cells, 15,200 per c.mm.; polymorphonuclears, 39 per cent.; lymphocytes, small, 13 per cent.; lymphocytes, large, 6 per cent.; eosinophiles, 2 per cent. No myelocytes or mast cells seen. The motions were brown or yellow in colour—not acholic; but the urine was deeply coloured and contained bile pigment. Wassermann reaction negative. After persisting for three months the jaundice has been gradually getting less during the last two months. The liver edge is now 1¾ in. above the umbilicus, but the spleen has slightly increased in size. A recent count shows a change in the blood picture: Red corpuscles, 2,360,000 per c.mm.; white cells, 38,000 per c.mm.; polymorphonuclears, 50 per cent.; lymphocytes, small, 28 per cent.; lymphocytes, large, 4.7 per cent.; myelocytes, 13.3 per cent.; eosinophiles, 3.7 per cent.; mast cells, 2.2 per cent. Nucleated red corpuscles are present, and a few of the myelocytes contain eosinophile granules. Hydropic degeneration of the nucleus is frequent, especially in the myelocytes and the large lymphocytes. The urine is still pigmented and contains bilirubin, but no urobilin.

Dr. Leonard Guthrie showed a case of

CONGENITAL INSUFFICIENCY OF OCULAR AND FACIAL MOVEMENTS

in a boy, æt. 4. At birth imperfect closure of the eyes was noticed and also that the face was devoid of expression. The whole face is motionless as far as the mouth; the skin of the face is smooth and not tightly stretched. The eyes cannot be fully closed, the eyeballs are in mid-position, the only ocular movement is convergence downwards and inwards. Pupils equal and react to light, less so to accommodation. Laughter is only represented by guttural grunts. The orbicularis oris is not paralysed, this being probably due to association of its action with that of the tongue. Electrical reactions cannot be obtained in any of the facial muscles except the orbicularis oris. The condition is regarded as an unusual form of myopathy affecting muscles supplied by the 3rd and the 7th nerves.

Dr. F. Langmead showed a case of "Cretinism." The appearance of the patient, a female child, aged five months, is characteristic. The child was shown because she exhibits two features which are characteristic of mongolian imbecility rather than of cretinism—(1) markedly incurved little fingers, (2) congenital morbus cordis.

Dr. E. Bellingham Smith showed a case of (?) "Cerebellar Encephalitis." The boy, æt. 8, was admitted as a case of cerebrospinal meningitis. July 25th: Sudden onset with headache, vomiting and aching pains. On admission the next day the boy was drowsy, face flushed, rigidity of the neck muscles, and some retraction of the head. The abdomen was retracted, reflexes exaggerated, plantar reflexes extensor, Kernig's sign and ankle clonus well marked. Temperature 103° F. Lumbar puncture revealed a turbid fluid, not under pressure, containing 0.075 per cent. albumin; globulin in a small precipitate. Glucose present, also many polynuclear cells and large lymphocytes. No organisms seen, cultures sterile. On August 8th commencing optic neuritis was noticed, which became more marked. On September 4th fluid from a second lumbar puncture was also sterile. September 9th, no paresis of the limbs, but well-marked ataxia, the inco-ordination being equally present on both sides. On September 15th the patient was put on pot. iod., since when the symptoms have rapidly cleared up, and the child seems now practically well.

Dr. Bellingham Smith also showed a case of "Infantile Paralysis" of early onset and with unusual deformities. The disease attacked the child when only two months old. It is now quite unable to sit up, and usually lies with both knees flexed and the hips abducted so that the thighs lie at right angles to the pelvis. The left leg can be readily brought down into a direct line with the trunk, but the right is incapable of complete inward rotation and abduction.

Dr. Porter Parkinson showed a specimen of "Neoplasmoid of the Sigmoid Flexure" from a boy, æt. 5. When admitted to hospital on July 17th there was a distinct, rounded, movable, tender lump, the size of an orange, in the right iliac fossa. On Sept. 29th, after several motions containing large quantities of blood, the child died. At the necropsy, the lump was found to be a distended sigmoid colon lying in the right iliac fossa and adherent to the adjacent small intestine. The walls of the sigmoid were much thickened with hard, whitish growth, the inner surface being ulcerated. A microscopical section showed largish, rounded, and tailed cells packed in the meshes of fibrous tissue alveoli. In the opinion of Dr. Porter Parkinson and of others the growth is a carcinoma.

Dr. J. D. Rolleston showed a specimen of extensive

DIPHTHERIA OF TRACHEA AND BRONCHI

from a girl, æt. 5. The specimen shows membrane closely adherent to the posterior surface of the epiglottis and interior of the larynx, from the lower end of which a thick continuous tubular cast extends to the bifurcation of the trachea and passes into each of the bronchi.

Dr. F. G. Crookshank showed a skiagram of a case of "Anomalous Development." The lower limbs were small, immobile, and presented webbing between the thigh and the calf. At the *post-mortem* examination it was found that the spinal column terminated at the 12th dorsal vertebra in a bony boss of small size. The spinal canal was completely closed. There were twelve pairs of dorsal nerves, but no lumbar nerves at all; and the legs were, seemingly, not innervated. A very rudimentary sacrum and coccyx were present. For several months before and after the date of the child's conception the mother had been in close daily association with a little boy, paralysed as the result of Pott's disease, who died when the mother was four months pregnant.

Mr. Duncan Fitzwilliams showed a specimen of "Extra-pleural Lipoma" from a child, æt. 6. The case had been shown at a meeting of the section in January as a case of lymphangeioma, resembling hernia of the lung. The swelling gradually became larger, and in September the lump was exposed and removed. It proved to be a pure lipoma with very little fibrous tissue. The portion in the neck communicated by a narrow isthmus growing down behind the subclavian artery with a much larger portion which lay within the thorax outside the parietal pleura. The tumour, which was very soft, was removed whole.

SECTION OF OPHTHALMOLOGY.

MEETING HELD WEDNESDAY, NOV. 5TH, 1913.

The President of the Section, Sir Anderson Critchett, Bart, F.R.C.S., in the Chair.

Mr. Sydney Stephenson showed a case of brawny scleritis at an early stage, which Mr. Treacher Collins thought was tenonitis. He had had a case of this condition, which persisted for a long time, as had this one. Mr. Holmes Spicer reminded the meeting of a case with similar appearance which he showed at a former meeting under the title "solid œdema of conjunctiva." That, however, had a syphilitic origin, which apparently was not the case here.

Dr. Deighton Davies spoke of a case under his care with a similar appearance. A small portion was examined and found to consist of round cells without a stroma. He enucleated, and on bisecting the globe he found a darkly pigmented sarcoma. He suggested the present case was one of sarcoma.

Mr. J. L. Barley showed a case of "keratitis punctata," and Mr. Killick one of complete persistent hyaloid artery.

Mr. A. S. Cobbledick showed an example of "ectasia of the cornea" four years after a perforating wound; and a case of rupture of choroid in a myope following labour. The latter he regarded as unique of its kind.

Mr. Bishop Harman showed a patient with new growth causing detachment; and

Mr. George Coats exhibited a dog with keratitis.

Mr. Chatterton showed a case of

TUBERCULAR IRITIS,

in order to elicit opinions as to the value of tuberculin injections for the condition.

Mr. Browning said he had treated a considerable number of such cases with tuberculin, and he knew of no case in which hæmorrhage had followed its use. The French seemed to think the hæmorrhages in this disease were of tubercular origin.

Mr. Mayou said he had treated numbers of cases of tubercular iritis with tuberculin and had not seen hæmorrhages during the treatment, which resulted in the absorption of the nodules and the subsidence of the iritis. It was the most successful way of treating the disease. He gave tuberculin provided there was no large tubercular lesion elsewhere, such as phthisis. He commenced with 1/10,000th, and worked up to as much as 1/250th T.R. Where lung trouble existed also, 1/100,000th caused severe reaction.

Mr. Macnab said he had recently treated two cases in this way, and both did exceedingly well.

Mr. Arnold Lawson confirmed the experience of other speakers.

Mr. Parsons showed a central unilateral retinitis.

Mr. **Hugh Thompson** showed a case of choroiditis starting as a ring round the macula.

THE LATE MR. NETTLESHIP.

The **President** made sympathetic reference to the death of Mr. Edward Nettleship, which brought a loss not only to the Society, but to the world of ophthalmology. Though evidently in failing health, his mental vigour was such that even as late as the recent International Medical Congress, he took a part in the discussions. His own memory of Mr. Nettleship carried him back to the time when he was curator at Moorfields, and he, Sir Anderson, was senior clinical assistant, and both Mr. Critchett (the speaker's father) and Sir Wm. Bowman had the highest opinion of Mr. Nettleship's knowledge as a pathologist. Yet with all his ability and knowledge he always bore himself with modesty. A resolution of condolence with his family was carried by all present upstanding.

Mr. G. **Coats** read a paper in which he reported some examples of

DISEASE IN THE ANIMAL EYE.

He described a form of keratitis characterised by the presence of a superficial vascular opacity in the cornea. The disease was of long duration, and had no evident association with distemper or other general illness. It sometimes occurred in more than one member of the same litter. Pathologically, it consisted in a replacement of the superficial layers of the cornea by a layer of inflammatory tissue. The human condition which it most nearly resembled was trachomatous pannus, but it differed from that disease in the absence of follicles, and of scarring or distortion of the lid, as well as by its not being confined to the upper part of the cornea. A case of retinal degeneration following distemper was described. The retinal changes were peculiar in that it was the bipolar cells of the inner nuclear layer which were chiefly affected, the ganglion cells showing only slight and probably secondary changes, the outer layers being mostly intact. In places, however, the rods and cones and their nuclei were also atrophic. These changes were most probably to be explained by the presence of a circulating toxine with a specific affinity for the retinal bipolars analogous to the specific action of nicotine on the ganglion cells.

A description of some cases of choroido-retinal degeneration and inflammation was prefaced by a discussion of the pathological points of distinction between these two conditions. A profound atrophy of the retina without adhesion to the choroid must be a degeneration. In old-standing cases of degeneration, however, an adhesion between the two membranes occurred, but it was usually not very intimate; the line of demarcation remained well defined, and the elastic lamina of the choroid was intact. The occurrence of cicatricial tissue was certain proof of precedent inflammation, and where it was present the adhesion was dense and the layers of the choroid and retina were distorted and disorganised, instead of being merely atrophic. A degeneration was often fairly uniform over a considerable area, an inflammation was patchy.

Examples of choroido-retinal degeneration in a dog, raccoon, wolf, wild sheep, ferret, wallaby, and hyæna were shown. The raccoon appeared to be an albino, yet a little pigment was present in the epithelium of the ciliary body and anterior part of the choroid, showing that pure albinism could not be diagnosed without a miscroscopical examination. The raccoon also showed nystagmus, a condition occasionally described in the lower animals. A case of choroiditis, cyclitis and keratitis in a bear, and one of anterior choroiditis in a peccary were also illustrated.

Two instances of canine irido-cyclitis were reported. The first was of plastic type, and was peculiar only in its occurrence in the dog, in which animal the condition appeared to be rare. The second, also in a dog, was characterised by an enormous thickening of the iris, due to infiltration with mononuclear cells of a special type. Posterior synechiæ and other features of plastic iritis were absent. The cause of the irido-cyclitis was obscure in both instances.

The paper was discussed by Mr. **Treacher Collins**, Mr. **Lawford**, Mr. **Sewell** (Veterinary Surgeon), Mr. **Rayner Batten**, Mr. **Bishop Harman**, Mr. **Holmes Spicer**, Mr. **Lang**, Mr. **Cruise** and the **President**, several of which gentlemen had been consulted in regard to animals' eyes; and Mr. **Coats** replied.

Mr. **Charles Wray** read a paper on

OBSTRUCTION OF THE LACHRYMAL DUCT AND ITS TREATMENT.

He believed it was a mistake to remove the sac when syringing failed, without attempting to cure by means of styles, or styles and probing combined, and thought it not unlikely that ectropion and its sequelæ might follow excision. Too much was heard of the satisfactory and immediate results, but too little of bad ones and of recurrences. After referring to the danger of adrenaline and chloroform when used at the same time, stress was laid on Harrison Butler's operation. According to the author, all cases of epiphora should be rhinoscoped, though he admitted he had received little or no help from the rhinologist. The author treated his cases in the following way: He injected cocaine by Mellen's method, and instilled a drop into the conjunctival sac. A Bowman's probe was then passed into the sac, and the point pushed forward under the palpebral ligament. He then cut down on the guide, taking care to note the click of the knife on the probe. So far the procedure was quite painless. He then placed crystals of novocain in the sac, and had recourse to probing. At times, if the stricture was impermeable, he forced a passage through the posterior wall of the duct. A piece of strapping was then placed just below the sac, so that the style when introduced did not press on the skin. A special style—gold-plated, and obtainable from Courlander, of Croydon—was then passed, and the latter was so constructed that when a piece of strapping was placed on its arms it could not move. Whilst it was *in situ*, argyrol 5 per cent. was used three times a day, or such other application as might be desirable. Later, when a firm-edged fistula had formed, the patient was instructed to irrigate the sac three times a day, passing the style at night and taking it out in the morning. To cure the fistula, it could be dilated, and while stretched all the cicatricial tissue cut away, after which the edges of the wound were brought together and covered with collodion. He proceeded to criticise the operations of Toti, Eichen and West. The first of these consisted in making a large open window between the sac and the nose, and as the nose in cases of lachrymal obstruction was so very often diseased, the operation, in his judgment, could scarcely receive the approval of ophthalmic surgeons. And the patient experienced considerable annoyance on blowing his nose, and the operation provided no vertical tube like the duct to carry the flow of tears opposed to the entry of organisms to the sac. Eichen side-tracked the tears to the antrum—*i.e.*, converted this cavity into a pool of stagnant tears. It also had the same objections as those urged against Toti's operation.

West's operation was for obstruction low down in the duct, and consisted in removing its nasal wall. It was better than the two foregoing operations, as some of the duct was left, but it had the serious objection that autolavage and autoprobing were impossible. The aim of the operation was to make a permanent fistula in the middle meatus, but the task of making one in erectile or semi-erectile tissue in a canal the size of a crowquill was almost impossible; and in the event of the duct being kept open by constant probing *via* the nose or canaliculus, the erectile tissue would be so damaged that a fibroid stricture would be bound to follow. He said his object was not so much to attract attention to his own operation as to obtain a formal expression of opinion as to the value of the newer operations of Toti, West and Eichen.

The will of the late Mr. Walter Whitehead, of Colwyn Bay and Manchester, surgeon, has been proved at £176,892 18s. 9d. net.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Meeting held Wednesday, November 5th, 1913.

The President, Mr. J. M. Cotterill, in the Chair.

Dr. John Playfair was elected President of the Society.

Mr. Cotterill then delivered his valedictory address, in which he dealt with the work done by the Society during the two years that he had been its president.

Dr. Ninian Bruce gave a communication on

THE SUPRARENAL GLANDS: THEIR COMPARATIVE ANATOMY, PHYSIOLOGY, PATHOLOGY, AND RELATION TO CLINICAL MEDICINE.

After dealing with the comparative anatomy of the suprarenals, Dr. Bruce referred to their rich vascular supply and its explanation in a direct secretion of adrenalin into the blood.

The adrenalin had a very powerful and very rapid action in constricting vessels and raising the blood-pressure. The effect was of very short duration. A repetition of the dose was followed by an identical result. A reduction in the dose was followed by an equivalent reduction in the effect. The effect could be prolonged by perfusing animals with very dilute solutions over a long period. The suprarenals maintained the normal tone of the cardio-vascular system. It acted on the neuro-muscular junctions, and only through the sympathetic system. The effects were similar whether the stimulus was through the sympathetic nerves or by the chemical secretion of the suprarenals. The whole of the sympathetic supply of the cardio-vascular system could be removed, since all the fibres passed through a few ganglia. Animals so treated did not die, but removal of the suprarenals was fatal. The chemical factor was the more important. A condition of suprarenal exhaustion might arise in certain circumstances. If guinea-pigs were killed with diphtheria toxin there was great congestion of their suprarenals. The extracts made from such suprarenals had no effect on the cardio-vascular system of cats.

The change in the suprarenals due to diphtheria was indirect, not specific. A similar exhaustion could be caused by other acute infections, metallic poisons, ricin and extreme fatigue. In Addison's disease the amount of adrenalin supplied to the blood gradually diminished. In acute cases there might be no pigmentation. It was suggested that in diphtheric toxæmia with heart failure, in asthenia after typhoid and influenza, and other conditions, the underlying factor might be suprarenal exhaustion.

Sudden death after removal of half of the thyroid for exophthalmic goitre might be partly due to a simultaneous affection of the suprarenals, and before such operations the blood-pressure should be examined. The treatment of suprarenal inadequacy was chiefly preventive. When it was suspected any increase of fatigue was to be avoided. The great difficulty in the administration of suprarenal was the rapidity with which it was used up. Some means of giving a continuous supply was required.

Dr. Byrom Bramwell said that the pigmentation in Addison's disease might be likened to the eruption of a fever. It might be absent or very slight, and more stress was to be laid on the asthenia. He had always been disappointed in the results of giving suprarenal in Addison's disease, but it was to be remembered that the underlying condition was generally a serious one. At present they were not in a position to accept the theory of suprarenal exhaustion to account for diphtheritic heart failure. There were gross myocardial and nerve lesions in that condition. He did not think that pigmentation in cases of exophthalmic goitre was necessarily evidence of suprarenal disease.

Professor Caird thought the paper embodied a useful piece of experimental pathology which might become applicable to the human subject. The two great difficulties at present were how to know when their patients were in danger of being carried off by suprarenal exhaustion and the evanescence of the substance in the glands after death so that *post-mortem* evidence was not readily available.

Dr. Ker said that anything which would combat heart failure in diphtheria would be an immense boon, but adrenalin in his hands had not been a success.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Medicine.

Meeting held Friday, October 31st, 1913.

The President, J. O'Carroll, M.D., F.R.C.P.I., in the Chair.

PATHOLOGY AND TREATMENT OF DROPSY, IN RELATION TO COLLOIDS.

The President of the Academy (Dr. Walter Smith) read a paper upon this subject, in which he expounded some recent views upon the causation and pathology of œdema and dropsical effusions. The chief factors of œdema are these:—

(1) Vascular—*i.e.*, blood-vessels and lymph-vessels. (*a*) Increased supply or inflow of transudate; (*b*) obstructed or diminished outflow through (i.) lymphatics, (ii.) veins and capillaries.

(2) Osmotic pressure.

(3) Physico-chemical alterations in the blood.

(4) Alterations in cell nutrition—(*a*) Blood-vessels and lymph-vessels; (*b*) tissue cells; (*c*) nervous influences.

(5) Turgescence of cells.

Special emphasis was laid upon the condition of watery turgescence of cells, and illustrative experiments were shown in favour of the hypothesis of Martin H. Fischer (Cincinnati) that even a very slight degree of, or increase in, acidity leads to turgor of cells.

Renal and cardiac dropsy were respectively discussed, mainly from the colloid chemical point of view, and the bearings of this idea upon treatment were pointed out.

The President remarked that the paper was a most valuable one. Referring to the possibility of œdema occurring without any discoverable fault of the kidneys or heart, he directed attention to a form of acute moderate dropsy met with in alcoholic cases without any sign of renal difficulty when examined by ordinary methods. This condition was found to clear up rapidly after a few days' rest. The rarity of œdema in cases of mitral stenosis, and its frequent occurrence in connection with mitral regurgitation, was a matter of interest. With regard to the evil effect of saline purgatives in Bright's disease, it struck him that possibly it might be that the normal tendency of the kidney to get dropsical itself may be increased by the absorption of the common salt—sulphate of magnesium—which was so often administered in cases of dropsy. He was also struck by the evil effect of normal saline injections in inflammatory conditions, especially in acute pneumonia.

Professor Thompson inquired if all œdema included in the definition meant accumulation of fluid in the tissue spaces. He pointed out that tissue fluid was different from the fluid present in the lymph channels. The inhibition idea was not, he thought, brought home so closely to the circumstances as one would like, and it must be admitted that there were other factors which were potent in causing œdema. Alteration in capillary pressure certainly produced no influence on increase of fluid in tissues, except in the case of the liver. He considered that alteration in the capillary pressure without alteration in the cell walls had no influence in the production of œdema.

Drs. Parsons, Crofton and Bewley also spoke.

Dr. Ellen M. Pickard, M.D.Lond., has been appointed Medical Registrar to the Royal Free Hospital.

BRITISH OTO-LARYNGOLOGICAL SOCIETY.

Meeting held Wednesday, October 29th, 1913.

Dr. Walton Browne (Belfast) in the Chair.

A paper was read by Mr. Adair Dighton (Liverpool) on

SOME INTERESTING CASES TREATED IN A PROVINCIAL CLINIC.

The cases he reported were of cavernous sinus thrombosis, latent cerebellar abscess lightened up by the mastoid operation, osteo-chondroma of the auricle, labyrinthitis and meningitis following polyp extraction and symptomless lateral sinus thrombosis.

This paper was discussed by Mr. Charles Heath, Drs. Walton Browne, Fred Spicer, Coubro Potter and Walker Wood.

A paper by Dr. H. D. McCulloch on

THE THERAPEUTICS OF RADIO-ACTIVE AGENCIES IN DISEASE,

with special reference to the cure of chronic nerve deafness and deaf-mutism, which had previously been circulated among the Fellows, was then discussed.

Dr. McCulloch affirmed his priority in the discovery in 1908 of this method of otological treatment. Adverting to the vast difference that existed between ordinary therapy and radio-therapy, he alluded to the biochemical and biological interactions that occurred in the former, and the purely catabolic physical changes that ensued in the latter. He submitted reasons why the hitherto employed medicinal and mechanical means had failed to remove the underlying cause. He deprecated inflation of the tubes in chronic catarrhal states until resolution had been effected *in situ* by radio-active agencies judiciously employed. Incidentally, he drew attention to the important immunising effect in subacute infections, referring to his previous contributions on that subject and to the amount of corroborative evidence that had since accumulated abroad. He exhibited and described various minute apparatus in the application of radio-active agents, He mentioned his gratifying experience in a typical case of Menière's vertigo, and he drew special attention to the promise of success this method held out in preventing deaf-mutism, the notes of one case being given. The paper was concluded by a tabulated list of 64 cases of hopeless deafness treated by him in 1911.

Dr. Walton Browne drew attention to a case of oto-sclerosis reported at the recent International Otological Congress, markedly benefited by radium. In this case the improvement had been maintained.

Mr. Charles Heath congratulated Dr. McCulloch on his interesting and scientific paper.

Dr. Coubro Potter required further information as to the selective action of the rays. Why did they act on certain cells, the pathological ones, and not on the normal cells. Also he could not quite understand from Dr. McCulloch the particular class of case likely to benefit by the rays. He would also like further clinical evidence to support the claims of improvement by this treatment.

Mr. Adair Dighton discussed the paper entirely from the aural point of view. To commence with, he could not understand how any one method could be expected to cure such diverse conditions as had been given in the paper. Then he strongly objected to the statement that this treatment "promised to be a boon in the prevention of deaf-mutism," as this was not only misleading but on the face of things impossible. Again, he objected to the loose way in which the terms "acquired deaf mute," "chronic deaf mute," etc., had been used—both being unknown conditions.

Mr. Pullin, Drs. Fredk. Spicer and Walker Wood joined in the discussion, the latter stating that he had seen four cases of Dr. McCulloch's, and tested them before and after three months' treatment, and though the hearing had not much improved, there was an improvement.

In reply to Dr. Coubro Potter, Dr. McCulloch said that although it was common knowledge that generally speaking abnormal tissue cells were influenced to the exclusion of normal ones, the term "selective action" could not be scientifically employed. He offered an analogical explanation of a lens and beam of sunlight. In reply to Mr. Pullin and his criticism of Prof. Bragg's view, as compared with Prof. J. J. Thompson's concerning electrons and matter, he appreciated the former. He could not accept Mr. Adair Dighton's definition of the kinds of mutism. In reply to Dr. Frederick Spicer, he said that the prevention of dermatitis in employing radium or mesothorium could only be learned by experience. He offered to demonstrate on a future occasion how this was guarded against in using the X-rays.

Mr. Charles Heath gave a demonstration of the usual methods of

DRAINAGE OF SUPPURATING EARS.

He said that a persistent discharge from an ear is uniformly accompanied by disease in the mastoid antrum, no matter whether the discharge escapes through the tensa or through Shrapnell's portion of the drum-head. He pointed out (and illustrated his statement by moist specimens, diagrams and patients) that when discharge escapes through a perforation in Shrapnell's membrane, the change of route is due to the fact that the channel leading down to the tympanum inside the incus is obstructed by swelling of the mucosa of the inner attic wall, and that if the parts outside the incus (including Prussac's space and Shrapnell's membrane) were not unduly weak and capable of being perforated by the pressure of the pus, complete obstruction and acute mastoiditis would result. He exhibited diagrams of swollen mucous membrane obstructing drainage through the Eustachian tube, the tympanum, the attic and the aditus, and described the symptoms they each produce. One of the patients he exhibited had three weeks previously undergone a conservative mastoid operation for so-called attic suppuration. The disease had existed for two years; there was a perforation in Shrapnell's membrane with a polypus projecting through it; there were deafness to air conduction (a 50-inch watch being inaudible close to the ear), severe pain and vertigo. Since the operation the pain and vertigo had ceased, and the patient could already hear the watch at 4 inches. Mr. Heath stated that he had treated a considerable number of cases with perforation in Shrapnell's membrane, and while upon the operating table they all proved to be cases of mastoid disease draining on the outer side of the incus instead of (as usual) inside it; pathologically they were, therefore, not cases of attic disease at all. He asserted that it is only when discharge from the antrum descends inside the incus that it is able to reach the tympanic cavity and escape thence in the usual way through a perforation in the membrana tensa. He remarked that if the case he had exhibited had been one of epi-tympanic or attic disease as the books erroneously state, his operation upon the mastoid antrum alone would not have given such complete relief as has been afforded. The result proved that the disease was in the antrum, and further, it was observed to be there during the operation. Mr. Heath referred the Fellows to his article in *The Lancet* of April, 1907, where he recorded other cases of this kind, which were afterwards exhibited before the British Laryngological and Otological Society.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Nov. 8th, 1913.

Vaccination for Typhoid Fever.

Vaccination, preventive and curative, is now largely employed in France for typhoid fever. All the doctors have received official circulars drawing attention to this new and, as has been proved, effective treatment and stating that a supply of vaccine is at their disposition when necessary.

As a preventive this vaccine will become in time as popular as the Jenner vaccine, and will be freely used for children and adults in periods of epidemics. Last summer a severe outbreak of typhoid fever occurred in the town of Avignon; nearly half the population was vaccinated with the result that the epidemic was stamped out. Naturally severe hygienic measure were taken also.

As to the counter-indications, the anti-typhoid vaccine should not be employed in subjects suffering from any acute or chronic affection; coryza, grippe, tonsillitis, bronchitis, pulmonary or febrile gastric affections, enteritis. Among the chronic affections may be classed tuberculosis, malaria, syphilis, cardiac and renal disease, diabetes.

Generally, says Army Inspector Dr. Schweider, it would be well not to choose a moment of mental fatigue (studies for examinations) or where the patient is debilitated or at the menstrual period of women.

The vaccine is delivered in ampoules of 2, 5, 10, and 20 cubic centimetres. Each ampoule contains a label indicating its origin and the date of its manufacture. The vaccine must be kept in a cold place and away from the light, in this way it maintains its effect over three months.

The syringe used may be that of Pravaz or Luer, but of a capacity, at least, of two and a half cubic centimetres.

The seat of injection is the left shoulder (the right in left-handed persons) behind the posterior edge of the deltoid and two fingers' breadth above the axillary fold. The skin is first painted with iodine, and the liquid injected slowly beneath the skin, under the aponeurosis or into the muscle, and the patient recommended to keep his arm quiet for two hours.

The vaccination requires four injections at intervals of from seven to ten days at the following doses:—

1st injection, half a cubic centimetre.
2nd injection, one cubic centimetre.
3rd injection, a cubic centimetre and a half.
4th injection, two cubic centimetres.

For children these doses will be reduced by one half. A drop of tincture of iodine seals the little orifice.

Although the patients need not interrupt their occupations, certain precautions should be taken, as abstention, the day of inoculation, from all fatigue or excess in eating and drinking. They should be made to understand that they should not consider themselves as immunised until they have received the complete series of injections, and not before twenty days have elapsed since the last injection.

The best time of the day for the injection is from four to six in the afternoon, as if any reaction took place it would pass away unnoticed during sleep.

The duration of the immunisation is not, at the present time, definitely fixed, but it is supposed to cover two years and a half.

As curative treatment, the vaccination influences favourably the course of the malady when employed in the early stage and provided that the spleen is not too much enlarged. Preference should be given to autovaccine, but this is not easy to obtain; the choice rests with the hetero-polyvalent vaccine of Wright. Under its influence the fever goes down slowly but progressively, and convalescence is less prolonged.

Antigonococcic Vaccine.

M. Charles Nicolle, Director of the Pasteur Institute at Tunis, announces his discovery of a vaccine against gonorrhœa. M. Nicolle, who has already made many savant researches on cholera, trachoma, whooping-cough, etc., has been studying for the last year the arduous problem of microbiological treatment of blennorrhagia.

The treatment appears simple: three or four injection every two or three days of two centimetre cubes of a solution containing millions of micrococci. After the first injection pain and general malaise disappear. In chronic cases, the patients are cured after a third or fourth injection, and in acute cases fifteen days suffice for a permanent cure.

But it is in purulent ophthalmia, the cause of so much blindness, that the vaccine of the French savant produces its most wonderful effects. One simple injection cures this dreadful disease.

M. Nicolle, who has treated by his vaccine, with constant success, over 200 cases of gonorrhœa, including several cases of purulent ophthalmia, is about to deliver his secret to the medical world.

Purulent Otitis.

Syringe the ear morning and evening with a warm infusion of tea or camomile. Fill the canal with the following mixture, allowing it to remain ten minutes, the head inclined towards the healthy side. Remove the liquid in excess by a plug of absorbent cotton wool.

Boric acid, 1 dr.
Subnit. of bismuth, 1 dr.
Benzoic acid, 10 gr.
Formal, 3 drops.
Glycerine, 1 oz.

AUSTRIA.

Vienna, Nov. 8th. 1913.

Radium Treatment of Internal Disease.

Radium-therapeutics still continues to be a subject of clinical investigation everywhere, and the influence of that unique element on morbid processes in internal organs gives rise to considerable variety of opinion, as well as of reported observation. Dr. Fritz Kraus (Prague) has just published the results of his very extensive and prolonged researches. He has found that of all forms of internal disorder sciatica responds most favourably to the methods of radium-therapy. Next in order of susceptibility he places the subacute and chronic forms of articular rheumatism. Striking improvement was also shown under the continued application of the influence of the radiations in conditions dependent on arterio-sclerosis, claudicatio intermittens, and angina pectoris; some of the results and sequelæ of cerebral hæmorrhage also underwent very striking improvement. And when, in the treatment of selected cases, the methods of emanation therapy were combined with those of thermo-penetration, the results were found to be highly satisfactory.

Argentum-Therapy in Gonorrhœa of Males.

The Hegonon treatment of quite recent cases of acute blennorrhœa gives very favourable results; the medicament having the great advantages of easy solubility, with complete absence of irritating qualities. The class of cases in which it was found to be most satisfactory by Dr. Ernst Rosenfeld, who has just published his results, were those in which the gonococci were shown by microscopic examination to occupy for the most part an extracellular position in the purulent discharge. In such cases, a completely abortive result was obtained by the injection, three times daily, for three to five days in succession, and for five minutes each time, of a $\frac{1}{4}$ per cent. solution; which was followed in turn, for three to five days, by the use of Janet's fluid, of the strength of 1/3,000 to 1/1,000.

Treatment of Aphasia.

At the recent meeting of the K.k. Gesellschaft in Vienna, the subject of aphasia was discussed by Dr. E. Fröschels, who emphasised the objectionable features of the classification of cases of aphasia according to the Wernicke-Lichtheim scheme, and referred to the expressed views of many authorities, according to which the nerve path for the production of spontaneous speech was not a direct one from the trans-cortex to Broca's centre, but one which passed by the centre for voice production. With regard to the treatment, Dr. Fröschels did not believe that aphasic patients could learn language again through the ear in the absence of a spontaneous regeneration of the speech faculties; so that it is much more essential to approach the senses of sight and touch by showing the patient the movement of the lips in speaking, and making him feel the currents of air. With regard to comprehension of the varieties of aphasia, some important conclusions were drawn from the results of treatment, inasmuch as the subjects of cortical motor aphasia learn to repeat words after another speaker before attaining spontaneous powers of speech, and the condition thus becomes transmuted into a so-called transcortical motor aphasia; this latter variety must be regarded as a retrograde stage or milder form of the cortical. Furthermore, that the symptom-complex of motor aphasia may develop as the result of a partial functional failure of the centre for articulate speech; that is to say, especially when it interrupts the inflowing current of sound images from without; but it does not develop spontaneously. Dr. Fröschels calls this form expressive sensory aphasia, in contradistinction to the receptive sensory aphasia, in which the current of voice-producing images from without is not interrupted.

A Case of Industrial Argyria.

Dr. L. Teleky exhibited a patient who displayed highly developed argyria of industrial origin. The development of the cutaneous stain was due to the fact that he had been engaged for five years (as a *perleneinzieher*) in the production of glass pearls. His employment consisted in the introduction of a freshly-made mixture of silver nitrate solution with milk sugar into glass tubes, from which the glass pearls were afterwards prepared.

HUNGARY.

Budapest, Nov. 8th, 1913.

The Study of Constitutions in Pediatrics.

Dr. Heim Pal remarks that a bird's-eye view of the history of medicine in the last hundred years shows a periodical prevalence and recurrence of medical conceptions which he explains as the result of a periodical prevalence and recurrence of certain constitutional tendencies. They are not passing fashions of thought, but the logical outcome of the conditions that confront practitioners in different decades. The vogue of venesection two generations ago is a typical instance of this; people were shorter, stockier, and more plethoric, and venesection often was urgently indicated. Now the predominance of the lean, the nervous, and the anæmic forbids venesection for the majority of patients although its importance under proper indications is recognised. Not only the conditions of life and hygiene, but also the character of the pathogenic microbes are constantly varying. Children used to thrive on milk, eggs, meat, and butter, and some do so still; but he declares, if we attempt to push such a diet for the children of the present day, fully 70 per cent. will grow thin and pale and lose their appetite. Any attempt to feed such infants with fat, especially the fat of milk, or any over-feeding is liable to be followed by the development of eczema, milk crust, urticaria, prurigo, recurring pharyngitis or coryza, bronchitis, adenoid vegetations, mucous stools, etc. With restriction of the ingestion of fat, the symptoms subside. Finkelstein, of Germany, ascribes this exudative diathesis to defective metabolism, but it is not necessary to go behind the simple fact that these symptoms are elicited by fat in the diet, and tend to subside when the intake of fat is reduced. It is remarkable. Heim continues, that it is the fat of cow's milk which is most injurous; the infants can frequently bear pig fat or cod liver oil much better. He has seen eczema heal under a course of cod liver oil. There is nothing in these children to reveal the tendency to this diathesis until the manifestations develop. In children with the exudative diathesis the reaction to tuberculous infection assumes the familiar picture of scrofula. The larger part of the clinical picture of scrofula is an artificial product, the result of forced feeding with milk, eggs and butter or overfeeding of any kind, and this part of the clinical picture may be eradicated by dieting, while a course of tuberculin may modify for the better the tuberculous element in the syndrome. Scrofula is the exudative diathesis plus tuberculosis. This diathesis modifies likewise the reaction to all other infections. It is an everyday experience that such children take vaccination very hard, and they are particularly susceptible to "children's diseases," especially scarlatina. This disease is less common than measles, as many children seem to be immune to it, and since Czerny's views in regard to the proper diet and treatment of children with exudative diathesis have been practically applied to the children in Breslau by himself and physicians trained in his service, the number of cases of scarlatina in the town has fallen off to a remarkable extent. Heim goes still further and asserts that the severer form of scarlet fever, fatal in three or four days, occurs only in children with the exudative diathesis plus a neuropathic constitutional tendency. Malignant scarlatina is analogous to the fatal driving in of eczema which we now know to be the toxic sepsis of infants with the exudative plus the neuropathic tendency. The latter tendency, he continues, may be recognised by the floating tenth rib and flabby muscles, the general nervousness and unstable temperature. With this tendency alone a change from breast to cow's milk is often beneficial. The change to artificial feeding should generally be reserved for the pure neuropathic constitution. The latter is usually associated with the exudative diathesis, and in this event any fat in the artificial diet will do harm. In these cases the superimposed injurious influence of both diatheses is apparent; no change of diet seems to benefit, and some intercurrent infection is liable to carry off the infant. The indications in these cases are for exclusive or mixed whey or buttermilk diet. Prurigo is a symptom of the exudative diathesis, he says, but the itching reveals the neuropathic tendency, as also the croup and asthma in the laryngitis and bronchitis due to the exudative diathesis. Further research on prevailing constitutional tendencies viewed from a broad outlook will certainly, Heim declares, open a new horizon for successfully influencing the health of the rising generation.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

GLASGOW.

Dr. James A. Adams's Candidature for Assessorship.

Dr. James A. Adams, who has just recently demitted office as President of the Royal Faculty of Physicians and Surgeons of Glasgow, was, on the 29th ult., at the half-yearly meeting of Glasgow University Council, nominated as one of their assessors in the University Court. As the two retiring assessors were also both nominated for re-election and the show of hands taken at the meeting could not be regarded as conclusive, a poll was demanded. Dr. Adams has now issued his address to the electors, the members of Council. In it he points out that while he represents primarily the interests of the graduates in medicine, he is also in touch with the interests of the teaching profession. He refers to the influence of the University over the extra-mural medical colleges and to the proposals concerning the inclusive fee, as to which, however, he does not state his views. Finally, he points out that the medical graduates are inadequately represented as regards numbers in the University Court, and he states that there has long been an impression that scientific and medical research has not been sufficiently encouraged in the University, apparently because the funds at the disposal of the Court have been allocated to less essential purposes. Dr. Adams's candidature will no doubt be supported by the medical profession, and especially by those members of it who have been connected, like him, with the Glasgow Royal Infirmary.

Glasgow Municipal Election.

The medical candidates in Glasgow municipal election met, as was to be expected, with divers luck. In the first place Bailie Dr. Edward McConnell, a tried representative, was returned to the Council without opposition. Another tried representative, however, Dr. James Erskine, was beaten at the polls by an untried candidate. The third medical candidate, Dr. D. McKellar Dewar, was successful in ousting a

Labour or Socialist member of the Council. Dr. Dewar is thus a member of the Council, and the number of medical members is five, as before.

Salaries for Assistant Medical Officers.

At a meeting of the Glasgow Parish Council on the 4th inst., the Chairman, in moving the approval of the minutes of the Chairman's Committee, drew attention to the new scale of Salaries for Assistant Medical Officers. He pointed out that there was a difficulty in getting assistant medical men to fill positions under the Council when vacancies occurred. They all knew, he said, that the Insurance Act had raised the value of medical service very materially, and that it was getting more and more difficult to get any men to accept office at salaries which were to some extent nominal. The Committee had, therefore, after full consideration, resolved to recommend that practically £50 be added to the early salaries when appointments were made.

At the same meeting the Clerk of the Council stated that, notwithstanding the Insurance Act, the outdoor medical staff in the respective districts had still as much work to do as formerly.

Principal Sir Donald Macalister, who has been seriously unwell for some time, is now recovering.

LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

THE ETHICS OF JOURNALISM.

To the Editor of The Medical Press and Circular.

Sir,—To me it is not at all surprising to find that in the few days which have elapsed since my last letter was written there have appeared a number of glaring illustrations of the facts I referred to. I send enclosed two advertisements from London papers which, as you can avouch, stand in the very front rank of journalism. These advertisements are printed in leader type among editorial matter. One occupies a full column, the other a smaller space. They are both distinguished by the sign "advt." at the foot in very small letters. The longer one belongs to a new development in a form of cruel quackery that has been exposed over and over again. It contains some obvious falsehoods; and if its character were not at once recognisable by astute editors and managers, it ought to have, at least, excited serious suspicion, and ought not to have been printed without inquiry. The shorter advertisement announces a new venture by a foreign impostor who styles himself "doctor." Its author is evidently akin to the class of swindlers of the same type often hailing from the United States who periodically exploit the simple British public. He undertakes to cure with one secret nostrum many groups of symptoms which are often classified under one name, but which are due to a great variety of totally different causes calling for equally varied treatment. A third advertisement which I enclose is from one of the leading provincial papers—a paper of great influence, always quoted among its fellows by its London contemporaries when the opinion of the country at any crisis needs making known. This paper goes one better. It prints a lengthy fraudulent puff among editorial matter without any sign whatever to mark it as a paid advertisement. The medical Press has nothing to do with commercial fraud, albeit doctors, not being business men, are commonly among its victims. It would be well if they could be warned against putting any trust in financial advertisements promising an easy way to wealth. Some time ago a great paper allowed its City editor to expose the character of some of these frauds, whilst at the same time they were being freely advertised in its own pages. I have preserved a copy of this paper.

I am, Sir, yours truly,

Henry Sewill.

The Old Rosery,
Earlswood Common.
November 8th, 1913.

To the Editor of The Medical Press and Circular.

Sir,—Although I have profound admiration for the man who, having unearthed a scandal, harries it as he would a fox that had been continually robbing his hen-roost until it was caught and destroyed, yet I cannot but think your correspondent, Mr. Sewill, might resign his attempts to suppress quackery as a hopeless quest. Not only do the leading newspapers pander to quacks in the most blatant fashion by publishing advertisements of the cruelest frauds on the public as editorial articles for the revenue the practice brings to their coffers, but one cannot pick up even the most reputable of magazines without one's eyes are caught by mendacious statements of the most marvellous so-called cures of blindness, deafness, heart-disease, consumption and the like to which flesh is heir. Unfortunately, the English Press, with a few honourable exceptions, has of late seemed bent on exploiting those illicit sources of income made notorious in their American prototypes, and so long as our Government derives a handsome revenue from the sale of patent medicine stamps, I fear it is a hopeless war to wage even in the public interest.

Recently one has noticed with pleasure that the county of Kent has prohibited the erection of hoardings which have in the past disfigured the fair countryside of the "Garden of England" with their obnoxious announcements of pills and the like cure-all-diseases. But there the movement stops, so far as England is concerned, and were your correspondent to travel across the American continent by train he would find matters still worse, whole tracts of country being literally hidden, and even the trees utilised with advertisements of this nature. Some of these even go so far as to announce that they "don't even ask a cent for the cure," yet their noble self-sacrificing proprietors can afford to pay heavy fees for publishing the intelligence that it has been effected "after the most eminent doctors have failed." Such is the gullibility of the public in this twentieth century of progress!

I am, Sir, yours truly,

A Sympathiser.

November 10th, 1913.

FAITH-HEALING (?) AT UNIVERSITY COLLEGE.

To the Editor of The Medical Press and Circular.

Sir,—*The Times* of November 6th contains a report of a meeting at University College on the previous day "to mark the opening of a medico-psychological clinic in London." Lord Sandwich presided. The following excerpts from his speech will enable your readers to estimate its quality and character. He said that "the mind had an immense power over the body. He did not pretend to medical or surgical science. There were few serious maladies he had treated without success. He might say he had never failed to relieve people in agonies of pain. There were people who dubbed him an impostor, and possibly a liar, but that was a matter of indifference to him, as he knew pain had been alleviated and the sick healed. He had been asked to explain his power, but he had nothing to explain; he only knew what happened. If he was possessed of that power there must be many others possessed of lesser powers of healing." The only medical speaker, Dr. Constance Long, seems to have made no reference whatever to Lord Sandwich's address. No doubt his statement will receive the serious consideration of the scientific and medical staffs of University College and Hospital. The profession surely, if not the public, are entitled to some explanations. Is it proposed to treat serious maladies of which the most prominent symptom may be "agonising pain," without attempting a diagnosis, and merely by relieving the pain by any possible means? It would be easy to name scores of surgical conditions alone in which mere suppression of pain must end in disaster, and often provide simply an euthanasia—lead to a perfectly preventable, albeit painless, death. If it seemed of any use one might feel inclined to urge Lord Sandwich to inquire into the nature of some of the cases of "agonising pain" which might be likely to present themselves at a University College clinic under the direction of "healers" like himself, who "do not pretend to medical or surgical science." In this connection, and in the case of a highly intellectual man like Lord Sandwich, a little learning for once would not be a dangerous thing. It might be an enormous advantage to himself if not to his patients if he would inquire into the nature of some of the cases of severe pain likely to be met with at the proposed clinic. It would not be difficult for Lord Sandwich to learn the nature and origin of the pain, say in such diseases as glaucoma, strangulated hernia, syphilitic gumma and inflammation of bone, cancerous and simple tumours involving nerves, acute appendicitis and gall-stones. With this knowledge he would recognise that medical and surgical science provides methods of diagnosing and relieving or curing a vast number of diseases which could not be dealt with successfully by any other means not purely miraculous. I have tried to confine myself to a mere statement ot facts. These, I think, are more than sufficiently important to claim a place in your pages; and as no point of honour or etiquette seems to call for my signature, I beg to be allowed to subscribe myself

Yours truly,

Scrutator.

London, W., November 7th, 1913.

THE RESTAURANT FLY.

To the Editor of The Medical Press and Circular.

Sir,—May I ask your attention for a moment to a point in practical sanitation that is curiously neglected by most of our sanitary authorities, namely, the presence of flies in restaurants. To the scientific mind there can hardly be a more disgusting object than a fly hovering about a table and from time to time alighting on bread, sugar, sauces, gravy, meat, and so on. The observer knows that the fly, following the instincts and the facts inherent to his life-history, has emerged from the nearest manure heap, or from any decaying garbage, animal or vegetable, which may be in the vicinity. It follows, of course, that the fly may bring to the viands any of the bacteria, pathogenic and non-pathogenic, that abound in fæcal and other forms of filth. Yet this source of danger to the citizen is preventable. Remove the breeding places of the flies and they will cease to reproduce their kind, especially if at the same time they are destroyed wholesale when they have wandered inside buildings. Why is the restaurant-keeper allowed to expose his customers to the annoyance and risk of disease conveyed by flies, when it is possible for him to rid himself of every one of these dangerous little pests by the use of formalin solution and other well recognised means of prevention? Why, indeed, unless it be the reluctance of Health Committees to interfere with the vested interests of licensed restaurants.

In the city of Prague, I learn from a paragraph in the *Daily Graphic* of November 4th, flies are few and far between—an immunity that is attributed to the soundness of sanitary rules and regulations. Why should London be behind Prague in so important an item of health?

Yours truly,

D. Walsh.

Harley Street, W.
November 9th, 1913.
